OpenStax

OpenStax provides free, peer-reviewed, openly licensed textbooks for introductory college and Advanced Placement® courses and low-cost, personalized courseware that helps students learn. A nonprofit ed tech initiative based at Rice University, we're committed to helping students access the tools they need to complete their courses and meet their educational goals.

Rice University

OpenStax is an initiative of Rice University. As a leading research university with a distinctive commitment to undergraduate education, Rice University aspires to path-breaking research, unsurpassed teaching, and contributions to the betterment of our world. It seeks to fulfill this mission by cultivating a diverse community of learning and discovery that produces leaders across the spectrum of human endeavor.

Philanthropic Support

OpenStax is grateful for the generous philanthropic partners who advance our mission to improve educational access and learning for everyone. To see the impact of our supporter community and our most updated list of partners, please visit openstax.org/foundation.

UNIT 5 CARE OF THE SURGICAL PATIENT

PREFACE

About OpenStax

OpenStax is part of Rice University, which is a 501(c)(3) nonprofit charitable corporation. As an educational initiative, it's our mission to improve educational access and learning for everyone. Through our partnerships with philanthropic organizations and our alliance with other educational resource companies, we're breaking down the most common barriers to learning. Because we believe that everyone should and can have access to knowledge.

About OpenStax Resources

Customization

Medical-Surgical Nursing is licensed under a Creative Commons Attribution 4.0 International (CC BY) license, which means that you can distribute, remix, and build upon the content, as long as you provide attribution to OpenStax and its content contributors.

Because our books are openly licensed, you are free to use the entire book or select only the sections that are most relevant to the needs of your course. Feel free to remix the content by assigning your students certain chapters and sections in your syllabus, in the order that you prefer. You can even provide a direct link in your syllabus to the sections in the web view of your book.

Instructors also have the option of creating a customized version of their OpenStax book. Visit the Instructor Resources section of your book page on OpenStax.org for more information.

Art Attribution

In *Medical-Surgical Nursing,* art contains attribution to its title, creator or rights holder, host platform, and license within the caption. Because the art is openly licensed, anyone may reuse the art as long as they provide the same attribution to its original source.

Errata

All OpenStax textbooks undergo a rigorous review process. However, like any professional-grade textbook, errors sometimes occur. In addition, the wide range of evidence, standards, practices, data, and legal circumstances in nursing change frequently, and portions of the text may become out of date. Since our books are web-based, we can make updates periodically when deemed pedagogically necessary. If you have a correction to suggest, submit it through the link on your book page on OpenStax.org. Subject matter experts review all errata suggestions. OpenStax is committed to remaining transparent about all updates, so you will also find a list of past and pending errata changes on your book page on OpenStax.org.

Format

You can access this textbook for free in web view or PDF through OpenStax.org, and for a low cost in print. The web view is the recommended format because it is the most accessible—including being WCAG 2.2 AA compliant—and most current. Print versions are available for individual purchase, or they may be ordered through your campus bookstore.

About *Medical-Surgical Nursing*

Summary

With more than half of all nursing students eventually working in medical and surgical environments, it is imperative that students build a solid foundation of knowledge, critical thinking skills, and patient-centered care practices to excel in these diverse settings. *Medical-Surgical Nursing* is designed to be a comprehensive guide for nursing students, equipping them with the essential knowledge and skills required to provide high-quality care. The ever-evolving field of health care demands that nurses be well-versed in both the science and art of nursing, capable of critical thinking, clinical judgment, and compassionate care.

Medical-Surgical Nursing encompasses a broad range of patient care situations, from managing chronic conditions

to providing post-operative care. The text balances concise explanations to facilitate understanding with rich reviews of pathophysiology, ensuring students grasp essential concepts without becoming overwhelmed. As a result, students come away with a deep understanding of the underlying mechanisms of diseases. *Medical-Surgical Nursing* integrates current best practices into each chapter. By staying informed about the latest advancements in medical-surgical nursing, students can deliver the highest quality care to patients. Beyond theoretical knowledge, the text emphasizes the development of practical skills and competencies. After reading *Medical-Surgical Nursing,* students will be better prepared to use their clinical judgment and critical thinking skills in a fast-paced environment.

Pedagogical Foundation

Medical-Surgical Nursing utilizes a blend of constructivism and experiential learning as its pedagogical framework. The text incorporates visual tools such as diagrams, flowcharts, and infographics to help students internalize complex information and create long-term understanding. Building on the foundational knowledge and skills acquired in previous nursing courses, this textbook expands students' learning with advanced concepts in medical-surgical nursing.

By encouraging students to apply their knowledge through real-world scenarios, case studies, and hands-on exercises, the textbook fosters experiential learning that enhances critical thinking and clinical decision-making skills. This approach not only prepares students for the complexities of medical-surgical nursing but also empowers them to provide high-quality, evidence-based care to their patients.

Organizational Framework

The table of contents for *Medical-Surgical Nursing* presents content in 38 chapters, organized into 7 thematic units.

- **Unit 1** establishes the foundational principles of medical-surgical nursing, covering professional practice, inter-collaborative care, health policy, evidence-based practice, and the integration of technology in health care. It also addresses culturally competent care and health promotion strategies.
- **Unit 2** focuses on the critical thinking skills essential for nursing by exploring the nursing process, clinical judgment, and ethical decision-making. It provides frameworks for recognizing, analyzing, and prioritizing patient care needs.
- **Unit 3** covers comprehensive health assessments and the management of pain, stress, and chronic illness. It emphasizes holistic patient evaluations and the development of effective communication skills.
- **Unit 4** details the management of various physiological conditions, such as fluid and electrolyte balance, respiratory and cardiovascular care, musculoskeletal and integumentary health, and more. It provides practical guidelines for patient care management.
- **Unit 5** guides students through the surgical experience, from preoperative to postoperative care. It highlights critical roles in ensuring patient safety, managing pain, and promoting healing and recovery.
- **Unit 6** addresses specialized topics such as genetics, oncology, palliative care, emergency care, and disaster response. It prepares nurses to handle specific conditions and scenarios with confidence and competence.
- **Unit 7** offers practical applications through unfolding case studies and NCLEX preparation. These sections enable students to integrate their knowledge and apply it in real-world clinical situations, fostering the transition from student to professional nurse.

Nursing Features

To further enhance learning, *Medical-Surgical Nursing* includes the following features:

- **Clinical Judgment Measurement Model** boxes guide students through the application of the Clinical Judgment Measurement Model. The content explores the critical thinking and decision-making processes necessary to navigate patient care at different points in the process, from recognizing cues to evaluating outcomes.
- **Clinical Safety and Procedures (QSEN)** align with the Quality and Safety Education for Nursing competencies by providing detailed explanations of safety protocols and procedures specific to medical-surgical nursing. This feature emphasizes the importance of patient safety and quality care and offers checklists, step-by-step, or tips on various safety practices.
- **Cultural Context** boxes explore the impact of cultural factors on nursing procedures and practices. Some features describe care provided in other countries, while other features discuss cultural considerations for

patients in the United States. Cultural Context boxes encourage students to approach each patient individually, respecting their culture and values.

- **Life-Stage Context** features describe topics that are affected by a patient's age. Age-related topics allow the students to critically think about what influences certain conditions and the specific considerations needed for patients at different life stages.
- **Link to Learning** features provide a very brief introduction to online resources—videos, interactives, collections, maps, and other engaging resources that are pertinent to students' exploration of the topic at hand.
- **Interdisciplinary Point of Care** features highlight the collaborative nature of modern health care by identifying the plan of care from various disciplines, including physical therapy, occupational therapy, social work, nutrition, pharmacy, case management, and respiratory therapy. These features help students appreciate the interdisciplinary approach to patient care, emphasizing the importance of teamwork in achieving optimal patient outcomes.
- **Read the EHR boxes** present students with real electronic health record (EHR) data, such as lab results, progress notes, or vital signs, for a specific patient. Each feature includes critical-thinking questions that challenge students to analyze the data, identify concerning information, determine expected findings, and question any anomalies. This exercise helps students develop the skills necessary for effective EHR utilization in clinical practice.
- **Real RN Stories** feature firsthand accounts from registered nurses in the field. These stories help students make connections to topics on a deeper level.
- **Unfolding Case Studies** present a hypothetical client scenario that unfolds in three parts across chapters, with each subsequent part presenting new information on the same client, to help foster clinical judgment. In each part of an unfolding case feature, the scenario is followed by two questions that require students to apply their knowledge of evidence-based care and allow them to practice with questions that mimic the style of Next-Gen NCLEX. The answers to these questions, with explanations, are included in the Answer Key for students at the end of the book.

Pedagogical Features

To support student learning, *Medical-Surgical Nursing* includes the following standard elements:

- **Learning Outcomes:** Every chapter section begins with a set of clear and concise student learning outcomes. These outcomes are designed to help the instructor decide what content to include or assign and can guide students on what they can expect to learn and be assessed on.
- **Assessments:** A variety of assessments allow instructors to confirm core conceptual learning, elicit brief explanations that demonstrate student understanding, and offer more in-depth assignments that enable learners to dive more deeply into a topic or history-study skill.
  - **Review Questions** test for conceptual apprehension of key concepts.
  - **Check Your Understanding Questions** require students to explain concepts in their own words.
  - **Reflection Questions** and **Competency-Based Assessment Questions** dive deeply into the material to support longer reflection, group discussion, or written assignments.
  - **What Should the Nurse Do?** and **Critical Thinking About Case Study Questions** assess students' clinical judgment skills using case-based scenarios. Students review either a single case or an unfolding case that reveals information gradually. In response to their observations of the patient, students must decide how to navigate the Clinical Judgment Measurement Model process. This approach challenges them to apply theoretical knowledge to practical situations, determining the most appropriate interventions based on the patient's specific circumstances.
- **Answers to Questions in the Book:** The assessments are intended for homework assignments or classroom discussion; thus, student-facing answers are not provided in the book. Answers and sample answers are provided in the Instructor Answer Guide for instructors to share with students at their discretion, as is standard for such resources.
- **Chapter Summary:** Chapter summaries assist both students and instructors by outlining the primary subtopics addressed within the chapter.
- **Key Terms:** Key terms are presented in bold text and are followed by an explanation in context. Definitions of key terms are also listed in the end-of-chapter glossary.

- **References:** References are listed at the end of each chapter.

About the Authors

Senior Contributing Authors

Senior contributing authors (left to right): Christy Bowen, Bridget Carey, Jessica Palozie, Maren M. Reinholdt

Christy Bowen, Chamberlain University. Dr. Christy Bowen DNP, RN serves as the Dean of Academic Affairs for Chamberlain University's BSN-Online. Dr. Bowen holds an ASN from Excelsior University, a BSN in Nursing and MSN in Nursing Education with a focus in Curriculum Development and Revision from Western Governor's University, and a Doctor in Nursing Practice in Nursing Leadership and Management from Capella University. Dr. Bowen has been a nurse for more than 20 years and is certified in the specialty of Critical Care nursing, and Wound Care. In her clinical practice she held roles such as Department Chair, Unit Educator, and Lead Nurse. In her Academia role, she has served as Lead Instructor, Curriculum Chair, Program Coordinator, Program Director, and Associate Dean of Faculty. Dr. Bowen has taught courses throughout all levels of nursing education such as associate, bachelor, master, and doctoral level programs. She enjoys teaching both clinical and didactic learning for nursing students. Dr. Bowen served as a key member of the curriculum team to develop a Concept-Based Curricula as part of the Texas Nursing Concept-Based Curriculum (TxNCBC) project; develop a standardized concept-based curriculum for the state of Texas. She has led over 50 Workshops as part of the Implementation and Customization service for schools across the US transitioning to Concept-based Nursing. She developed over 20 Board of Nursing Continuing Education (CE) Certified Workshops and presented as Keynote speaker for all workshops to Universities and Colleges across the US. Throughout Dr Bowens career she has received many prestigious awards including Nurse of the Year, Clinical Nurse Leader of the Year, Employee of the Year, Top Requested Nursing Education Consultant (NEC), Phi Theta Kapa Faculty Member of the Year, and Presidential Award Outstanding Faculty Service.

Bridget Carey MSN, RN, CWCN, LNC is an esteemed nurse leader and educator with over 15 years of clinical and academic experience. She holds a Bachelor of Science in Nursing (BSN) from Gwynedd Mercy University, a Master of Science in Nursing (MSN) with a focus on Nursing Education and Curriculum Development from Western Governor's University, and is a Board Certified Wound Care Nurse via graduate of the Rutgers School of Nursing's Wound Ostomy and Continence program. Bridget served as didactic and clinical adjunct faculty for the BSN-Express program at Holy Family University. Bridget is a published Medical Writer and Legal Nurse Consultant with a passion for advancing the field through evidence-based practice, innovative teaching methods, and elevating patient stories to foster systemic improvements. With experience as an active clinician and working across the continuum of health care, Bridget continues to weld the art and science of nursing by serving patients and providers from the classroom to bedside and boardrooms. She has reviewed and authored nursing curricula and clinical practice support with Wolters Kluwer/Lippincott, EBSCO and Dynamic Health, The Journal of Visualized Experiments (JOVE), HealthStream and Relias. She has authored, reviewed, and published several Continued Education courses for health-care providers, including a Wound Care 101 course with Texas Tech University.

Jessica Palozie, University of Connecticut. Dr. Jessica Palozie DNP, APRN, ACNP-BC, CNE has been an educator and practicing clinician for over a decade, specializing in acute care nursing with a focus on BSN and APRN students. As an Assistant Clinical Professor, she is deeply committed to the teaching philosophies of Benner and Bandura, tailoring education to meet the unique learning needs of her students. Dr. Palozie emphasizes the importance of leading by example and instilling confidence in student nurses, fostering both skills and knowledge essential for navigating today's complex health-care environment. A graduate of the University of Connecticut's Doctor of Nursing Practice (DNP) program, Dr. Palozie's academic journey also includes a Master of Science in Nursing (MSN) from UConn, a Post Master's Certificate in Nursing Education from the University of Hartford, and a Bachelor of Science in

Nursing (BSN) from Hartwick College. Her clinical interests include cardiology, women's health with a focus on infertility, and the integration of evidence-based practice (EBP) into clinical thinking. Dr. Palozie's research explores the adoption of EBP beliefs and attitudes among associate-prepared nurses, with a vision to increase the utilization of EBP guidelines in clinical practice. Dr. Palozie's dedication to education and research has been recognized through several prestigious awards, including the April 2018 Merit Faculty Award for her innovative integration of historical Hartford landmarks into nursing education and the October 2018 21st Century Grant for curriculum development. Her contributions continue to shape the future of nursing education and practice.

Maren M. Reinholdt, University of Rochester School of Nursing. Maren M. Reinholdt PhD, MSN, RN, CNE is an experienced educator of traditional, second degree/accelerated, and masters pre-licensure nursing students. She holds a BSN from Johns Hopkins University, a MSN in Nursing Education from Gonzaga University, a PhD in Nursing from Indiana University of Pennsylvania, and a BA in English, Theatre, and Secondary Education from Albright College. She has spent most of her time in clinical care in adult inpatient neurology and neurosurgery. She has coordinated and taught in-person and online in the didactic, laboratory, simulation, and clinical settings for Adult Health/Medical-Surgical Nursing, Child Health, Pathophysiology and Pharmacology, and Writing for Nursing courses. Dr. Reinholdt is a member of NLN, is a Certified Nurse Educator®, and a member of Sigma, International. Heather Moore, Xavier University.

Additional Resources

Student and Instructor Resources

We have compiled additional resources for both students and instructors, including Getting Started Guides, an instructor's answer guide, test bank, and image slides. Instructor resources require a verified instructor account, which you can apply for when you log in or create your account on OpenStax.org. Take advantage of these resources to supplement your OpenStax book.

Instructor's answer guide. Each component of the instructor's guide is designed to provide maximum guidance for delivering the content in an interesting and dynamic manner.

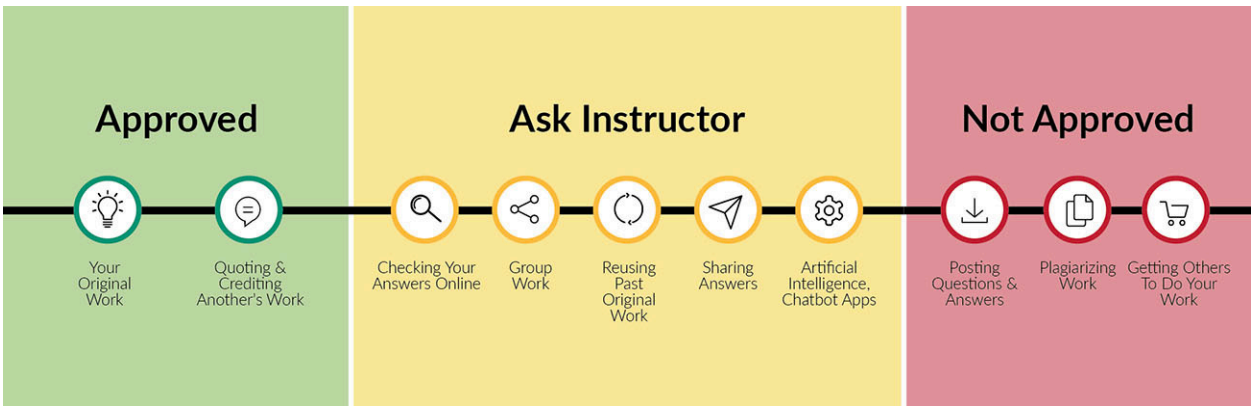
Test bank. With more than 1,100 assessments, instructors can customize tests to support a variety of course objectives. The test bank includes review questions (multiple-choice, identification, fill-in-the-blank, true/false), short answer questions, and long answer questions to assess students on a variety of levels. The test bank is available in Word format.

PowerPoint lecture slides. The PowerPoint slides provide learning objectives, images and descriptions, feature focuses, and discussion questions as a starting place for instructors to build their lectures.

Academic Integrity

Academic integrity builds trust, understanding, equity, and genuine learning. While students may encounter significant challenges in their courses and their lives, doing their own work and maintaining a high degree of authenticity will result in meaningful outcomes that will extend far beyond their college career. Faculty, administrators, resource providers, and students should work together to maintain a fair and positive experience.

We realize that students benefit when academic integrity ground rules are established early in the course. To that end, OpenStax has created an interactive to aid with academic integrity discussions in your course.



Visit our academic integrity slider (https://view.genial.ly/61e08a7af6db870d591078c1/interactive-image-defining-academic-integrity-interactive-slider). Click and drag icons along the continuum to align these practices with your institution and course policies. You may then include the graphic on your syllabus, present it in your first course meeting, or create a handout for students. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

At OpenStax we are also developing resources supporting authentic learning experiences and assessment. Please visit this book's page for updates. For an in-depth review of academic integrity strategies, we highly recommend visiting the International Center of Academic Integrity (ICAI) website at https://academicintegrity.org/ (https://academicintegrity.org/).

Community Hubs

OpenStax partners with the Institute for the Study of Knowledge Management in Education (ISKME) to offer Community Hubs on OER Commons—a platform for instructors to share community-created resources that support OpenStax books, free of charge. Through our Community Hubs, instructors can upload their own materials or download resources to use in their own courses, including additional ancillaries, teaching material, multimedia, and relevant course content. We encourage instructors to join the hubs for the subjects most relevant to your teaching and research as an opportunity both to enrich your courses and to engage with other faculty. To reach the Community Hubs, visit www.oercommons.org/hubs/openstax.

Technology partners

As allies in making high-quality learning materials accessible, our technology partners offer optional low-cost tools that are integrated with OpenStax books. To access the technology options for your text, visit your book page on OpenStax.org.

Special Thanks

The Division of Digital Learning at the Texas Higher Education Coordinating Board (THECB) has a history of dedicated research initiatives, services, and programs that have advanced open education in Texas by providing support, advocacy, and resources to Texas institutions in their OER efforts. The Division maintains a diverse OER portfolio including OERTX, a digital library and community space for open education work. The leadership and collaboration of the Division of Digital Learning staff made the OER Nursing Essentials (ONE) project possible, throughout research, planning, and development phases of the eight-textbook series.

This work was supported in whole or in part by the THECB. The opinions and conclusions expressed in this document are those of the author(s) and do not necessarily represent the opinions or policies of the THECB.

CHAPTER 1
Professional Medical-Surgical Nursing

FIGURE 1.1 Medical-surgical nurses care for a variety of patients in many different settings. (credit: modification of work "All of Us Participant" by NIH Image Gallery/Flickr, Public Domain)

CHAPTER OUTLINE

INTRODUCTION Medical-surgical nursing has become one of the largest nursing specialties. Medical-surgical nurses provide care for adult patients of all ages who are preparing for or recovering from surgery, as well as for patients with complications related to a variety of long-term illnesses. Nursing care incorporates a diverse patient population and a variety of disease processes, enabling medical-surgical nurses to apply a broad knowledge base and become experts in their field. Medical-surgical nurses also develop advanced organizational and prioritization skills, as well as strong assessment and communication skills. They are the leaders who coordinate patient care among the interdisciplinary team.

Medical-surgical nursing is practiced in a variety of settings within the health-care industry. Inpatient settings include hospitals, skilled nursing facilities, and long-term care facilities. Outpatient settings include clinics, same-day surgery centers, other nontraditional settings, and patients' homes. For this reason, the medical-surgical field offers many options where nurses can choose to practice.

1.1 Professional Nursing Practice

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Review key concepts of professional nursing
- Describe the competencies for the Quality and Safety Education for Nurses and role of The Joint Commission
- Define the nurse's role in providing patient-centered care

Nurses are an asset to their communities. The nursing profession is a calling for many, and it is an essential component of quality health care. Nurses take on many roles, from patient advocates to wellness educators, while also providing direct patient care. The nursing profession has evolved in recent decades so that evidence-based practice (EBP) is now the focus of patient care. Nurses also provide holistic care in a variety of specialized roles.

Professional Nursing Concepts

In the 1800s, hospitals typically comprised three primary units: medical, surgical, and obstetrics. In the mid-20th century, little distinction was made between surgical and medical nurses. However, by the 1960s, surgical nursing had become its own specialty; medical-surgical nursing became a more distinguished specialty around 1991, and the profession has continued to evolve. Today, medical-surgical nursing is one of the largest nursing specialties (Joseph, 2019; American Medical-Surgical Nurses Association, n.d.-b).

The Nurse's Role

Nurses work on the front lines of health care. They assess patients' symptoms and vital signs, document changes in condition, and evaluate the response to treatment. They also administer medications and operate medical equipment. The nurse is typically the first health-care worker to recognize when a patient is having a medical issue. It is their responsibility to immediately report the issue to the relevant provider to avoid adverse outcomes. The nurse remains with their patient during the patient's course of treatment. The nurse follows the progress of each of their assigned patients and keeps their best interest at heart. Nurses may also serve as a patient's case manager, taking the lead in coordinating medical care and advocating for the patient's physical, emotional, mental, cultural, and spiritual needs.

Because nurses have many roles, they acquire deep knowledge in a wide range of fields. An individual nurse has many specific roles to choose from, including bedside nurse, health coach, nurse navigator, case manager, nursing supervisor, home health nurse, hospice nurse, health writer, and nurse consultant. Nurse leaders, or those who enjoy management, may choose a role such as unit manager, clinical manager, or director of health services. Roles for advanced practice registered nurses include nurse practitioner, clinical nurse specialist, nurse midwife, and nurse anesthetist; these nurses have advanced training from a higher-level degree program such as a master's or doctorate. Regardless of one's focus, being a nurse opens the door to many opportunities in a variety of settings, including entrepreneurship beyond the health care industry.

The nursing **scope of practice**—the range of activities a licensed nurse is permitted to perform—is determined at the state level by a two-step process: (1) the state legislature passes a law, known as the **Nurse Practice Act** (American Nurses Association n.d.); and (2) regulatory bodies, such as the state nursing board, then create and implement rules and regulations intended to protect the public. Each state has its own rules and regulations. It is imperative as a licensed professional to be aware of the limitations of your practice in the state in which you work and where to find this information.

LINK TO LEARNING

The American Nurses Association articulates the nursing scope of practice (https://openstax.org/r/77scopepractice) explaining the areas in which each type of nurse can act. It is critical that a nurse understands their scope and role in the profession.

Professional Organizations

Nurses can choose to belong to a number of professional organizations. One of the most significant ones, with which

most nurses are likely familiar, is the American Nurses Association (ANA). The ANA was founded in 1896 as the Nurses Associated Alumnae; it changed to its present name in 1911. Its goal is to advance and protect the profession of nursing. According to the ANA, "patients' interests are best served by a health-care system in which many different types of qualified health professionals are available, accessible, and working together—collaboratively" (American Nurses Association, n.d.). Formal membership in any nursing organization generally requires membership fees that help fund the organization's political lobbying activities to support the causes of nurses, expand research, collect and disseminate resources, and provide networking, and educational and specialty certification opportunities for its members.

Another important organization for medical-surgical nurses is the Academy of Medical-Surgical Nurses (AMSN), which was founded in 1990. The AMSN's commitment is to "quality patient care through professional development, certification, scholarship, and advocacy" (American Medical-Surgical Nurses Association, n.d.).

LINK TO LEARNING

Specialties within the nursing profession have professional associations and organizations that support education and provide a subset scope of standards of practice. For example, the Academy of Medical-Surgical Nurses (https://openstax.org/r/77amsn) is the only professional association specifically for medical-surgical nurses. The role and mission of the organization is to support medical-surgical nurses throughout their professional careers.

Quality and Safety Education for Nurses

The **Quality and Safety Education for Nurses (QSEN)** project focuses on preparing future nurses to promote the quality of care and safety of patients in health-care systems (QSEN Institute, n.d.-a). The QSEN is a framework that weaves best practices from the Joint Commission Accreditation Standards and the Magnet model. The QSEN aims to redesign the "what and how" of nurses' delivery of care to ensure high-quality, safe patient care. QSEN's vision is "to inspire health care professionals to put quality and safety as core values to guide their work," with a focus on the following six main competencies:

- EBP
- informatics
- patient-centered care
- quality improvement
- safety
- teamwork and collaboration (QSEN Institute, n.d.-b)

LINK TO LEARNING

To learn more about the QSEN project and access their resources, visit the QSEN website that describes knowledge, skills, and attitudes (https://openstax.org/r/77qsen) for nurses.

Joint Commission Best Practices

The Joint Commission, formerly Joint Commission on Accreditation of Healthcare Organizations, is an independent, not-for-profit, peer-review organization that sets standards for quality care, quality improvement (QI), and patient safety for any organization and workers in the health-care industry. The standards set forth from the commission become the foundation for best practices in the health-care industry, including nursing standards of care. The Joint Commission has the power to accredit health-care facilities, ensuring their compliance with guidelines set by the Centers for Medicare and Medicaid Services and enabling them to receive federal reimbursement for services.

The Joint Commission believes nurses play an important role in health care and should be involved in developing safety and improvement initiatives. This belief led to The Joint Commission's support and integration of the QSEN. Ongoing priorities of the nursing profession include, but are not limited to, improving standards and recommendations for infection prevention, workplace violence, suicide prevention, emergency management,

environmental sustainability, and health-care equity for all, which are tied to the QSEN. Furthermore, each year, The Joint Commission gathers information related to emerging patient-safety issues. This information is used to create specific programs for the organization's National Patient Safety Goals (NPSGs). NPSGs are critical organizational elements to reduce negative patient outcomes and improve delivery of overall quality of care. Examples of NPSGs include improving the accuracy of patient identification and improving the effectiveness of communication among caregivers.

LINK TO LEARNING

Read The Joint Commission's National Patient Safety Goals (https://openstax.org/r/77jointcomm) on their website.

Patient-Centered Care

One model known as **patient-centered care** (PCC) is designed to promote optimal individual outcomes. The model requires listening to patients to understand what they value most, then using the information as the catalyst for health-care decisions. PCC encourages the patient and family to be a part of the health-care team, actively collaborating in the decisions that will formulate a customized plan of care and guide treatment decisions for the patient.

Scope and Attributes of PCC

PCC is essentially personalized care; providers work with each patient to develop and deliver a customized plan of care. Common elements of PCC include:

- collaboratively coordinating care by including the patient and family as essential team members
- encouraging the patient's family, as defined by the patient, to be present in the care setting
- ensuring the organization's mission and values are driven by patient-centered goals
- equally valuing the patient's emotional well-being and physical comfort
- incorporating the patient's emotional, mental, spiritual, social, and financial perspectives into their care
- promoting compassionate, quality care, and patient safety
- providing the right care at the right time in the right place
- respecting the patient's and family's values, culture, and socioeconomic status
- sharing information in a timely manner so the patient and their family can make well-informed decisions

PCC benefits patients as well as health-care providers and organizations. Overall, it improves patient satisfaction scores and enhances the reputation of health-care organizations, which, in turn, influences reimbursement rates. PCC boosts morale and productivity among providers because they share in their patients' experiences and improves the efficient use of hospital resources, which subsequently provides improved, individualized patient outcomes ("What is patient-centered care," 2017).

Examples of PCC in Nursing

Of all members of the health-care team, the nurse spends the most time with a patient; thus, they play the biggest role in PCC. The nurse's role in PCC includes responsibilities such as

- ensuring the patient's needs and concerns are at the center of health-care decisions and treatment plans
- inviting family members to become part of the care team by participating during rounds or shift changes
- including the patient and family in discussions and treatment decisions
- knowing what is most important to the patient and honoring their directives
- providing timely updates for the patient and their family

REAL RN STORIES

Nurse: Lisa
Years in Practice: Ten
Clinical Setting: Medical-surgical unit

Geographic Location: South Carolina

Lisa, a nurse in South Carolina, is providing care for Mr. Marshall, who has diabetes and is noncompliant with his physician's treatment plan, resulting in frequent hospitalizations. Lisa has been a nurse on the medical-surgical floor for 10 years and has developed a trusting relationship with Mr. Marshall and his family. Lisa remains mindful of the importance of providing PCC for Mr. Marshall, despite his noncompliance.

Knowing it is important to her patient, Lisa confirms during each hospitalization that Mr. Marshall does not want to receive heroic measures if his heart should stop beating or he should stop breathing. Upon confirmation, Lisa ensures that a do-not-resuscitate order is signed by the patient and then filed in his medical record. Lisa goes the extra mile to ensure Mr. Marshall and his family are informed of the latest test results and includes them in the decisions for Mr. Marshall's plan of care during his hospitalization; they also participate in designing his discharge plans. Mr. Marshall isn't always easy to get along with, but because he trusts Lisa; they share a special rapport that contributes to his overall satisfaction while in the hospital.

Lisa is well respected at the hospital and among her team members because of her diligence in ensuring Mr. Marshall's interdisciplinary team functions in a cohesive manner. Working as a case manager, she updates the team regularly to ensure there are no delays in care. Lisa has found that her initiatives to promote PCC in conjunction with improved outcomes and patient safety have inspired her peers to implement similar processes with their patients. Not only have Lisa and her team's efforts become greatly appreciated by their patients, the hospital has given a special award to the medical-surgical unit for their continued efforts to promote patient satisfaction and ensure positive outcomes.

1.2 Intercollaborative Care

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the roles of members of an interdisciplinary health-care team
- Identify best practices for effective communication methods
- Define critical thinking and clinical judgment

A team-based approach called **intercollaborative care** is designed to promote person-centered care to improve patient and health system outcomes. This is achieved through shared responsibilities, interactive planning, and collaborative decision-making. When a team of health-care providers works closely with the patient and their loved ones to make quality health decisions, it is possible to provide holistic, **whole-person care** that focuses on all the patient's needs (National Center for Complementary and Integrative Health, n.d.).

There are many different generally, however, the goal of a **collaborative care model** is to manage patient care more effectively and to improve patient outcomes (Worsham, 2022a). Benefits of a collaborative care model include improved quality in care, reduced cost, and increased convenience to the patient. These benefits are achieved through a unified approach that uses data sharing, a streamlined referral process, and integrated scheduling.

The Intercollaborative Health-Care Team

Regardless of its specific composition, an intercollaborative care team aims to use PCC to achieve improved patient outcomes. The efficiency of the team is determined by each team member's ability to work cohesively and in tandem, creating a streamlined workflow of communication and delivery of care.

An interprofessional heath care team comprises many individuals from a range of disciplines, such as nurses, physicians, social workers, and dietitians. As intercollaborative team members, nurses have a great impact on PCC and optimal patient outcomes. The nurse's knowledge and experience contribute to the development, implementation, and ongoing improvement of quality care and patient safety as well as the associated initiatives within the health-care delivery system.

Members of an interprofessional team often work together in the same facility. However, teams may also include specialists who work in the community, such as pharmacists, chiropractors, and optometrists. Efficiency within the team structure is necessary for all members to work effectively together. To improve the efficiency of this process and create stronger teams, some practice groups choose to partner within the same location, such as a primary care

group and a behavioral health group, to collaboratively provide holistic care. Furthermore, the increasing availability of telehealth has streamlined the collaborative patient care process by allowing providers to coordinate with additional team members as needed.

When PCC is not implemented, patients may experience a lack of individualized attention and consideration of their unique needs and preferences. For example: Mary, a 65-year-old female grappling with a chronic health condition, undergoes a challenging hospital admission during which the health-care team primarily focuses on the medical facets of her illness, focusing on one component versus the whole person.

Throughout her stay, Mary receives minimal information about her treatment plan, potential side effects, and anticipated outcomes, yet she directed about what to do. The health-care providers overlook inquiring about her preferences, because of the busyness on the unit, leaving Mary feeling like a mere statistic rather than an individual with unique needs. The lack of personalized attention and understanding of her background and values results in an impersonal and disconnected health-care experience for Mary. Subsequently, the treatment plan prescribed for Mary fails to consider her lifestyle, values, and cultural background. The oversight leads to a lack of motivation on Mary's part to adhere to the prescribed regimen, which potentially could result in complications. The cumulative effect of neglecting preferences and Mary's emotional well-being diminishes Mary's trust in the health-care system, ultimately influencing her willingness to share crucial information and follow medical advice.

Communication

Communication is an essential component for establishing an effective workflow within the interprofessional team. Teams can set themselves up for successful communication by clearly defining each member's role and outlining their expected responsibilities; teams should then meet regularly to confirm everyone is fulfilling their responsibilities and catch potential problems before they negatively affect patients. All these efforts help promote a coordinated effort when providing collaborative patient care.

Effective Methods of Communication

Effective communication requires more than just speaking and writing well. It includes nonverbal communication such as interpreting facial expressions and body language, listening attentively, and developing positive relationships with colleagues, patients, and family members.

A variety of software options are available to enhance effective communication between intercollaborative team members. One key tool is the **electronic health record (EHR)**, a digital copy of a patient's medical history. EHRs, which will be further discussed later in this chapter, allow each team member to read the notes of other health-care professionals, avoid duplication, and better implement the patient care plan. Additional benefits of EHRs include written and legible documentation and dashboards that offer alerts to help the team avoid potential adverse events—for example, from inadvertently prescribing incompatible medications. Some EHRs can be shared with patient portals, enabling patients and providers to communicate directly across multiple platforms.

ISBAR Technique

The **ISBAR** technique is a common tool clinicians use to structure written and verbal communication about a patient's condition. It is easy to remember and helpful for highlighting the critical points that require immediate attention or action. Table 1.1 identifies the components that make up ISBAR.

ISBAR Technique	Description	Example
I = Introduction	Introducing who you are, your role, where you are, and why you are communicating	Hi, This is Susie Jones. I am the registered nurse in the Emergency Department caring for Ms. Kennedy. I am calling to give her transfer report.
S = Situation	A brief statement describing the problem	Ms. Kennedy is an 80-year-old woman in Observation Bay 321, admitted last night at 22:30. She arrived via ambulance from Marshall's Place Nursing Home, where she reportedly fell in the bathroom.
B = Background	A concise overview of the situation	Ms. Kennedy is diabetic and has Alzheimer disease. All supporting documentation has been entered into the chart, including a DNR. Family was notified of the fall by the nursing home. I contacted the son with an update after the admission. Family expected to meet with the physician this morning.
A = Assessment	Analysis or summary of what you observed or thought	Diagnostic X-ray reveals a left hip fracture. Physical examination shows bruising to the left hip. Skin warm, dry, intact. Patient reports severe pain. Morphine administered by emergency department staff at 01:30.
R = Recommendations	A suggested action to address the problem	Consultation scheduled with surgeon for this morning. Continue morphine as needed for pain. Follow-up with surgeon regarding next steps.

TABLE 1.1 Components of ISBAR

ISBAR provides a simple structure that can be replicated by each team member to keep communication on track, creating a workflow for the intercollaborative team while also promoting patient safety.

LINK TO LEARNING

The Institute for Healthcare Improvement provides this web page with information about SBAR, including downloadable guidelines and a worksheet (https://openstax.org/r/77ihi) for implementing the technique.

Influence on Critical Thinking, Clinical Judgement, and Decision-Making

Nurses are faced daily with complex situations and issues resulting from advanced technology, high-acuity care, ethical and cultural issues, and an aging population with complex disease processes. The decision-making process related to problem solving in health care is equally complex and requires critical thinking.

A multidimensional, systematic, and organized way of reasoning is known as **critical thinking**. It involves purposeful, outcome-directed thinking and requires mindfulness, effort, practice, and experience (Benner et al. 2008). Critical thinking skills develop over time as foundational knowledge and key concepts combine with nursing

experience. Critical thinking enables the nurse to draw conclusions that lead to creative and appropriate decisions that promote effective solutions and positive outcomes. Components of critical thinking include

- asking questions and gathering information
- validating and analyzing information
- drawing on past clinical experiences
- maintaining a flexible attitude
- considering available options
- formulating decisions

Nurses use **clinical judgment** to make decisions about patient care based on observations, assessments, and interpretations of relevant information, goes beyond the application of technical skills and involves the integration of both empirical knowledge and practical wisdom. Two nurses with different levels of clinical judgment may review the same data from a patient and arrive at opposite decisions regarding care. The nurse with better clinical judgment will be more likely to understand the data and consequently to make a better decision that produces a better outcome for the patient (American Association of Colleges of Nursing, n.d.). The National League for Nursing has taken a firm stance that clinical judgement is a better problem-solving approach than the nursing process (Ignatavicius & Silvestri, n.d.).

Applying both critical thinking and clinical judgement in nursing care decisions is called **clinical decision-making**. Critical thinking enables nurses to sift through all the data and make evidence-backed decisions. Clinical judgement is the synthesis of the information, and clinical decision-making is the result. When nurses use this skill, they draw on their own experiences with patients as well as relevant, quality research they have gathered to choose the best course of action for a particular patient in a particular context.

Let's summarize and provide applicable examples of critical thinking, clinical judgment, and clinical decision-making.

- Critical thinking: A nurse critically assesses a patient's EHR, noting a sudden change in vital signs. Critical thinking is demonstrated as the nurse questions potential causes, considers relevant factors such as medications or recent interventions, and decides to gather additional information through direct patient assessment or by consulting with other health-care team members. The nurse analyzes the situation to form an initial hypothesis about the cause of the changes in the patient's condition.
- Clinical judgment: In a fast-paced emergency department setting, a nurse is caring for a patient with chest pain. Clinical judgment comes into play as the nurse integrates subjective and objective data, recognizing the urgency of the situation. The nurse forms a comprehensive understanding of the patient's condition, considering potential diagnoses and anticipating the need for prompt interventions such as an electrocardiogram or administration of medication. Clinical judgment guides the nurse in prioritizing actions to ensure the patient receives timely and appropriate care.
- Clinical decision-making: A nurse, after critically analyzing a patient's laboratory results and using clinical judgment to understand the implications, engages in clinical decision-making. In this scenario, the nurse decides to collaborate with the health-care team to adjust the patient's medication dosage and initiate additional monitoring. Clinical decision-making involves selecting the most appropriate interventions based on the analysis of data and the application of clinical judgment to improve patient outcomes. The nurse actively participates in creating and adjusting the patient's care plan to address the evolving clinical situation.

Clinical Judgment Measurement Model

The National Council of State Boards of Nursing developed the Clinical Judgement Measurement Model as an evidence-based framework to identify and enhance the cognitive skills essential for nurses to make effective clinical judgments. The model comprises six key cognitive skills:

1. Recognize cues: Identify relevant information or cues from the patient's condition and the health-care environment.
2. Analyze cues: Critically examine and interpret the collected cues to form a comprehensive understanding of the situation.
3. Prioritize hypotheses: Evaluate potential hypotheses or explanations for the patient's condition and prioritize them based on their significance and relevance.

4. Generate solutions: Develop a range of possible interventions or solutions in response to the prioritized hypotheses.
5. Take action: Implement the chosen interventions or actions on the basis of the generated solutions, considering the patient's unique needs and the clinical context.
6. Evaluate outcomes: Assess the effectiveness of the interventions by evaluating the outcomes and comparing them to the expected results. This step involves reflecting on the success of the chosen actions and making adjustments if necessary.

The Clinical Judgement Measurement Model outlines a systematic approach to clinical judgment, emphasizing the cognitive skills required for nurses to make informed and appropriate decisions in the complex health-care environment. The model guides nurses through the process of recognizing and analyzing cues, prioritizing hypotheses, generating solutions, taking action, and evaluating outcomes. This structured framework supports nurses in developing and applying their clinical judgment skills, contributing to improved patient care and outcomes. This topic is discussed further in a later chapter.

1.3 Health Policy and Ethical Considerations

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe health policy and the role of the nurse as they relate to patient-centered care
- Identify social determinants of health
- Explain core principles of ethics and their application to health care

Health policy regulates the delivery of health-care, with the focus on optimal patient outcomes. Everyone has the right to have access to the highest quality and safest care, regardless of their social status or other factors that might affect their health. This idea is the core of health-care reform, an important issue of our day. Ethical considerations are also key to ensuring that all patients are treated fairly and justly, with dignity and respect. Ethical health care promotes trust and confidence.

What Is Health Policy?

The laws and regulations that define the actions and decisions that promote a society's health goals make up its **health policy**. Regardless of one's profession or position in society, everyone has a stake in health policy. Nurses, however, have a unique perspective because they work directly with patients, observing firsthand the types of reform that would best serve the community.

Advocacy in Nursing

Nurses have a frontline role in direct patient care, giving them firsthand experience in all aspects of the health-care system. As direct care providers, nurses also understand what individual patients value the most—a key consideration in providing quality PCC. Nurses varied experiences enable them to provide a voice of expertise as advocates for health-care reform, particularly with respect to the delivery of care and patient safety. With the support of the ANA, nurses work diligently to make their voices heard at all levels where health policy decisions are made.

The Affordable Care Act

The Affordable Care Act (ACA) led to a significant regulatory overhaul and expansion of health-care coverage in the United States. It was signed into law in March 2010 to promote health equity throughout the country. The goals of the ACA include providing health coverage without limits and protecting people with preexisting conditions. The ACA has led to historic health-care advancements, enabling millions of Americans to have access to essential health benefits such as preventive care, wellness visits, rehabilitative care, mental health care, and prescription medications.

Social Determinants of Health

Factors that appear to fall outside of the healthcare system but play an active role in the health outcomes of a population are called **social determinants of health (SDOH)**. They include environmental factors (e.g., where one was born, where one grew up), as well as a broader set of factors that shape daily life, such as access to health care and education, economic stability, community development, social and society norms, education, and political

systems. A person's race and ethnicity can also play roles in their health; for example, certain groups are genetically predisposed to certain diseases. Examples of SDOH include

- access to healthy food and physical activity
- education, language, and literacy skills
- job opportunities and income
- race and ethnicity
- safe housing and transportation

SDOH can result in health disparities and inequities, which is why it is important for public health organizations to partner with education, transportation, and housing sectors to improve underserved residential communities.

Ethics

The study of right and wrong actions is called **ethics**. Each profession has its own code of ethics, providing an agreed-upon framework for making and evaluating decisions. In this respect, ethics is different from morality. Although the terms are often used interchangeably, ethics generally refers to standards of right and wrong that are agreed on by a particular community (e.g., a professional nursing organization); morality refers more to a personal standard that an individual uses to determine what is right and wrong.

Nurses make life-and-death decisions daily, making ethics an especially important foundation for the nursing profession. Ethical decision-making respects the patient's rights and individuality and ensures equitable treatment and care that aligns with each patient's beliefs and values (Sinaiko et al. 2019; Ethics in health care 2023). The ANA and other professional nursing organizations work diligently to develop ethics and human rights policies at the state, national, and international levels. The ANA Center for Ethics and Human Rights was established to help nurses navigate the ethical complexities of life-and-death decisions commonly found in everyday practice. Regardless of the present-day challenges in health care, the ANA's Code of Ethics for Nurses unites nurses in advocating for safe, quality care for all patients and communities, regardless of socioeconomic status.

LINK TO LEARNING

Read the entire ANA Code of Ethics (https://openstax.org/r/77anaethics) on their website.

Ethics in Nursing

The nursing code of ethics provides a solid foundation for nurses as they navigate the complex health-care system. It reminds nurses to keep several ideals foremost in mind as they make decisions and practice their skills. The following are four main principles in the field of nursing ethics:

- Patient **autonomy** acknowledges that patients have the right to maintain control and make their own decisions related to treatment and care.
- Provider **beneficence** refers to the health-care provider's responsibility to act in their patient's best interests. The ANA defines beneficence as "actions guided by compassion."
- The principle of **justice** means treating all patients fairly.
- Provider **nonmaleficence** refers to the health-care provider's responsibility to do no harm (Gaines, 2023).

CULTURAL CONTEXT

Patient Dilemma: Cultural Context in Health Care Decision-Making

Scenario

Imagine a patient—let's call him Mr. Nguyen—who finds himself grappling with difficult health-care decisions without a clear understanding of his treatment options. Mr. Nguyen, an older adult who has emigrated from Vietnam, lacks fluency in the local language and faces barriers in accessing culturally appropriate health-care information. Furthermore, he has no family members available to assist him in making critical decisions, such as choosing

between treatment options or considering a do-not-resuscitate order.

Cultural Barriers to Understanding

Mr. Nguyen's cultural background and language barriers present significant challenges in navigating the health-care system. Without access to information in his native language or cultural context, he struggles to comprehend complex medical terminology and treatment plans, which hinders his ability to actively participate in decision-making processes regarding his care.

Nursing Role in Cultural Competence

In such cases, nurses play a pivotal role in bridging cultural gaps and advocating for culturally sensitive care. By recognizing Mr. Nguyen's unique cultural needs and communication preferences, nurses can collaborate with interpreters or cultural liaisons to ensure he receives information in a manner that aligns with his cultural beliefs and values. Through patient education and empowerment, nurses empower individuals like Mr. Nguyen to make informed decisions about their health care, ultimately promoting health equity and enhancing patient outcomes.

Ethical Dilemmas

Nurses will inevitably face ethical dilemmas due to the nature of their work with people. Regardless of the specific circumstances of a given dilemma, here are some common causes of ethical dilemmas in nursing:

- assignments that are contradictory to personal, cultural, or religious beliefs or to the Code of Ethics for Nurses
- burnout associated with unsafe practices
- complicated family dynamics of patients
- dishonesty of peers
- hostile work environments, such as bullying in the workplace
- life and death decisions that must be made
- patients who refuse treatment
- short staffing or staff who fail to meet their responsibilities

Avoiding ethical dilemmas is impossible, but equipping yourself with knowledge and resources to face these dilemmas is essential. The most important thing is to deal with each situation in a professional manner that promotes quality care and patient safety.

The best way to recognize an ethical dilemma is to take notice of how a situation causes you to think and feel. You may feel pulled in two directions as you consider two courses of action. Neither course of action may be clearly incorrect; instead, each may emphasize different principles and values. You may feel you have to choose between right and wrong or that either choice could have negative consequences. Your facility should have some resources to help you make your decision, so be sure to consult them.

Examples of Ethical Dilemmas in Nursing and Health Care

Ethical dilemmas come in all shapes and sizes. Table 1.2 describes a few examples.

Dilemma	Possible Solution
Holly, a nurse on the medical-surgical floor, has been assigned to work on the postpartum floor due to short staffing. Although Holly has been a nurse for 5 years, she has limited experience working with postpartum patients. It is not uncommon for nurses to be reassigned to other areas, but the dilemma occurs when Holly finds herself being asked to provide care she does not regularly perform: helping a mother who is having trouble with breastfeeding.	Holly should notify a supervising nurse that she has limited experience with this type of care and ask for guidance. The supervising nurse should either accompany Holly to the patient's room to provide instructions for the patient and Holly, or assign an experienced nurse to help Holly. If the supervising nurse refuses to help, it might be necessary for Holly to contact the next highest person in the chain of command or to locate resources on how to teach a new mother about breastfeeding.
Bill is a new nurse. He has worked on the medical-surgical floor for a few weeks, but his training on the floor was cut short due to short staffing and he is working unsupervised for the first time. One of Bill's patients recently had a total hip replacement; there are orders for the patient to be turned every 2 hours. Bill doesn't feel comfortable turning his patient alone, knowing that he could cause harm to the new hip if the patient isn't turned properly.	Bill should contact his nursing supervisor to express his concerns. The supervising nurse should either assist Bill with turning the patient or assign an experienced nurse to help him; whoever assists should also take the opportunity to review the proper technique. If the supervising nurse refuses to help Bill, he should contact the next highest person in the chain of command or ask another nurse on the floor for help.
Steve and Sandy are nurses caring for cardiac patients. Today was an unusually busy day, which resulted in Steve forgetting to report to the physician that one of his patients experienced an abnormal spike in blood pressure. The patient's blood pressure returned to normal with no incident, so Steve chose not to document the occurrence. Later in the day, Steve told Sandy what had happened. Sandy now finds herself in a dilemma: she knows that nurses are responsible for providing safe, competent care for all patients and she ought to report Steve's error and bad decision; however, she worries this will damage what, to this point, has been a positive working relationship with Steve.	Sandy could begin by encouraging Steve to retroactively document the blood pressure spike and report it to the physician. If Steve still does not do this, Sandy should report the incident to the supervising nurse. It's true this might damage her working relationship with Steve, but the safety and well-being of patients are more important.

TABLE 1.2 Ethical Dilemmas

1.4 Evidence-Based Practice

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define evidence-based practice
- Discuss the components of nursing research and its applicability to patient care
- Differentiate between evidence-based practice in nursing and nursing research
- Discuss the applicability and impact of quality improvement initiatives on patient care

The process of **evidence-based practice** involves making clinical decisions based on the best available evidence from the most up-to-date research. By keeping up with the latest research, nurses can implement EBP into their patient care. Nurses using EBP promote better outcomes with reduced costs and increased patient satisfaction. Implementing EBP requires lifelong learning and a desire for QI in your nursing practice. It also requires disseminating evidence-backed results so other nurses can implement the same processes into their own practice—with the ultimate goal of improving policies throughout the health-care system. The ultimate return on this

investment will be nursing excellence.

EBP in Nursing

EBP enables nurses to implement best practices into patient care. Not only does EBP maintain the relevance of health-care practices, it also ensures practices remain current. Nurses involved in the delivery of care are instrumental in analyzing the **data**, or evidence, from current research and refining the processes related to QIs (which you will learn about later in this module). This firsthand knowledge is vital to continuous improvement of quality patient care.

EBP in nursing requires the critical thinking and judgment skills that come with experience and training. The nurse's decision-making process should include using research-based evidence in combination with their clinical expertise while also incorporating the patient's values and expectations into the process. This can be accomplished through the following actions:

1. asking clear questions to determine the patient's desired goals
2. learning to locate evidence from credible sources and read research reports critically
3. analyzing the validity of the evidence and research
4. applying the evidence to clinical practice, combining your nursing expertise with the new information
5. assessing the outcome to determine its efficacy and how it might benefit other patients

Using EBP in your nursing practice begins with identifying the specific issue or problem to solve. Nurses can then locate solutions that are appropriate for the population they are working with and share them with their patients and families to ensure they are part of the decision-making process. Doing all this enhances nursing autonomy, fine tunes critical thinking and confidence, and sharpens the nursing practice with new interventions and protocols.

Nurses who incorporate EBP into their practice also become more familiar with new technologies and treatments while promoting the growth of science in nursing and closing the gap between theory and practice. All these benefits help to ensure positive patient outcomes (Faubion, n.d.).

History of EBP in Nursing

Some believe the origins of EBP trace back to the 1800s, when Florence Nightingale gathered data and formulated conclusions related to unsanitary conditions and failing health while working as a nurse in military hospitals during the Crimean War (1854–1856). Nightingale brought to nursing a systemic, knowledge-based approach that relied on the best possible research and access to government statistics and expertise. Nightingale recognized that health data that governments routinely collected were not being used to inform decisions about health policy. Unfortunately, when Nightingale initially presented her ideas and philosophies, they were largely ignored, though her insights about using the best available evidence provided a useful framework for her own nursing practice.

The formal term *evidence-based practice* gained prominence in the latter part of the 20th century; however, along with Florence Nightingale, several major developments in the field of professional nursing paved the way for the integration of evidence into nursing care. Nursing research began gaining recognition as a formal field of study in the early to mid-20th century. The establishment of nursing research as a distinct field continued to evolve over several decades.

The late 19th to early 20th centuries saw a significant shift toward professionalism in nursing. For example, the National League for Nursing was established in 1893 and advocated for scientific principles in nursing education and practice. The nursing process began to emerge as a formal framework for EBP in the 1950s and 1960s. The introduction of the clinical nurse specialist role also occurred in the 1950s, reflecting a shift toward specialization and expertise within nursing. The mid-20th century saw the establishment and growth of nursing research journals, providing a platform for disseminating evidence. Then, during the 1970s and 1980s, there was an increased emphasis on developing evidence-based guidelines to standardize care. Systematic reviews and meta-analyses gained prevalence during this period.

The 1980s were also notable for the implementation of quality assurance (QA) programs. Hospitals began to implement QA programs to establish accountability to the community for appropriate, quality care and the associated costs. Eventually, The Joint Commission, formerly known as The Joint Commission on Accreditation of Healthcare Organizations, required QA programs for reimbursement of services and accreditation. The Joint

Commission then developed a model that included objective, measurable indicators to monitor, evaluate, and communicate patient care.

By the 1990s, health-care providers had recognized the difficulty of using criteria from regulatory agencies to measure quality of care. These criteria measured minimal expectations but did not identify problematic causes or processes for improvement. The resulting movement, named Continuous Quality Improvement, seemed a more effective mechanism to improve the quality of health care. Whereas QA focuses on incidents and errors, Continuous Quality Improvement focuses on the interrelated processes that affect patient outcomes and satisfaction. Consequently, The Joint Commission revised its standards to affirm patients' right to age-specific care that respects their dignity and their cultural, spiritual, and psychosocial values.

Nurses can be involved in QI in a variety of ways, including incorporating EBP into patient care guidelines. Because bedside nurses are involved in direct patient care, they are instrumental in analyzing the latest data and refining processes accordingly. Practicing EBP in this manner is a way to minimize the theory–practice gap. The **theory–practice gap** in nursing refers to the divide between theoretical knowledge acquired in academic settings and the practical application of that knowledge in real-world clinical settings. This gap can create challenges for nursing professionals as they attempt to translate theoretical understanding into effective patient care. Theoretical knowledge is essential for informed decision-making and EBP, but the ability to seamlessly apply that knowledge at the bedside is crucial for delivering quality patient care.

Nursing Research

Inquiry that is systematically designed to provide knowledge for important issues relevant to the nursing profession is considered **nursing research**. It is designed to generate evidence to help nurses make evidence-based decisions that improve the care and quality of life for their patients. Nursing research not only provides the data that inform EBP, it can also help in a variety of problem-solving situations. For example, by eliminating actions that do not achieve desired outcomes, nurses can help to contain the costs of care.

Approaches to Nursing Research

Many research opportunities and roles exist for nurses. As clinicians, nurses should remain informed about current issues and trends in their specialized area of clinical practice. Some nurses go further, using the best available clinical evidence to initiate QI projects in their practice. Other nurses become members of interprofessional teams to confront complex health problems, or they work as independent nurse-scientists and formulate a line of scientific inquiry. Researchers may conduct clinical studies to generate knowledge related to the guidance of clinical practice. They may work as a team, combining clinical, theoretical, and methodological skills to conduct collaborative studies. Regardless of one's role, common goals of nursing research are to better understand factors that affect health and illness; to discover innovative methods to detect, diagnose, treat, and prevent disease; and to justify changes to ineffective practices.

Research does not have to be complex or long term. Consider a floor nurse who asks patients to complete a simple, anonymous survey about their satisfaction with their hospital experience. Patients' responses can identify problems and point hospital staff toward potential solutions. Through these and other methods, each nurse can be a part of expanding the scope of nursing knowledge through the research they conduct, read, and disseminate.

Qualitative Research

A method called **qualitative research** focuses on personal experiences obtained through observation and interaction with patients. Table 1.3 describes common designs for qualitative research.

Design	Goal	Process
Phenomenology	To describe a phenomenon as an individual experiences it	Researchers interview people familiar with the specific phenomenon being studied, then draw conclusions based on the data.
Grounded theory	To understand how people are influenced by their interactions with other people and groups (Noble & Mitchell, 2016)	After interviewing each patient and their family members, researchers use the data to develop a theory about what they observed (Noble & Mitchell 2016).
Ethnography	To understand the influences of culture on individuals	Researchers interview members of the culture being studied, then synthesize the data into a description of that culture's unique characteristics and influences.
Narrative inquiry	To understand how an individual interprets specific events in their history	Researchers consider the content and structure of the narratives that each individual shares, then analyze each narrative for themes.

TABLE 1.3 **Qualitative Research Designs**

Quantitative Research

A method called **quantitative research** uses deduction and generalization from empirical evidence to draw conclusions. Objective data gathered by the senses from observations or experiments is known as **empirical evidence**. It is generally depicted by numbers in charts and tables for statistical purposes. Examples include identifying percentages, averages, and the mean of data. Researchers then determine whether the evidence supports or refutes the theory in question and to what extent conclusions can be generalized to a larger population.

Quantitative research can be experimental or nonexperimental. Experimental studies have an active intervention that affects the study participants, whose response to the intervention is measured. Experimental designs require a control to establish a correlational relationship between variables or make justified predictions. The experiments are usually double blinded, meaning information that may influence the participant or the experimenter is withheld until after the experiment is complete. This prevents biases either from the participant's expectations or the observer's assumption, which may influence the results. For example, researchers studying a new medication would not know which of the participants receives the medication and which receives a placebo; the participants would also be unaware.

Experimental designs include true experimental design and quasi-experimental design. In a true experimental design, the experiment is conducted in a controlled environment to study relationships, usually among two groups who receive different treatments through a randomly assigned process. Pharmacology research is a classic example that demonstrates whether a medication has a desired effect on the participant. A quasi-experimental design is similar to a true experimental design except it does not include random assignments.

A nonexperimental study offers no new intervention; instead, researchers closely observe study participants to analyze their behavior, or they analyze existing data to find patterns. Nonexperimental designs include descriptive studies and correlation studies.

Descriptive studies involve observing people or phenomena to provide a detailed depiction. In these studies, the observer describes the observed phenomenon, notes the frequency of its occurrence, and categorizes the gathered information. Essentially, descriptive studies aim to offer a comprehensive account of the characteristics and occurrences related to the individuals or events under observation. For example, one might observe and document the care practices in a hospital's critical care unit. The observer would detail the various nursing interventions performed (e.g., medication administration, wound care), note the frequency of each intervention, and categorize the information. In this descriptive study, the aim is to provide a comprehensive snapshot of the care activities in the critical care unit, shedding light on the common practices and their occurrence patterns.

Correlational studies focus on exploring the relationship between two variables. In these studies, researchers measure the identified variables, analyze the obtained data, and present their findings in statistical form. For example, a correlational study might investigate the relationship between the frequency of patient education sessions (variable A) and the level of patient adherence to a prescribed treatment plan (variable B). By measuring both variables and using statistical analyses, researchers can explore whether there is a correlation between the amount of education provided and the extent to which patients adhere to their recommended treatments. The results may help health-care professionals understand the potential impact of education on patient adherence.

Overview of the Nursing Research Process

The nursing research process is a systematic and organized approach nurse researchers follow to investigate and explore various aspects of nursing practice, patient care, and health-care outcomes. It involves a series of steps that guide the research process, from identifying a research problem to disseminating the findings. Here is a general description of the nursing research process:

1. Identify the research problem: The first step is to identify a research problem or question that requires investigation. This can be derived from gaps in knowledge, clinical observations, or the need to improve patient outcomes.
2. Review existing literature: Once the research problem is identified, a comprehensive review of existing literature is conducted. This helps the nurse researcher to understand what is already known about the topic and identify the research gaps that need to be addressed.
3. Formulate research objectives or questions: Based on the identified research problem, clear and specific research objectives or research questions are developed. These objectives or questions guide the direction of the study.
4. Design the study: The next step is to design the research study. This involves making decisions about the research design, sample size, data collection methods, and ethical considerations. The research design can be experimental, observational, qualitative, or quantitative, depending on the nature of the research question.
5. Obtain ethical approval: Before conducting the study, ethical approval must be obtained from the appropriate research ethics committee or institutional review board. This ensures that the study is conducted ethically and protects the rights and welfare of participants.
6. Collect data: Once the study design and ethical approval are in place, data collection can happen. Depending on the design, researchers may collect data through interviews, surveys, observations, medical records review, or other appropriate methods.
7. Analyze data: The collected data are then analyzed using appropriate statistical or qualitative analysis techniques. This helps researchers draw conclusions and answer the research objectives or questions in the next step.
8. Interpret and draw conclusions: The analyzed data are interpreted, and conclusions are drawn on the basis of the findings. The nurse researcher examines the results in the context of the existing literature and evaluates their implications for nursing practice, patient care, or policy.
9. Communicate findings: The next step is to disseminate the research findings to the wider nursing and health-care communities. This can be done through academic publications, conferences, presentations, or other appropriate means. Sharing the findings contributes to the advancement of nursing knowledge and informs EBP.
10. Evaluate and apply findings: Finally, the impact of the research findings is evaluated and considered for potential application in nursing practice. This may involve integrating the findings into clinical guidelines, protocols, or policies to improve patient outcomes and enhance nursing practice.

Throughout the nursing research process, it is important for nurse researchers to adhere to ethical principles, maintain the privacy and confidentiality of participants, and ensure the validity and reliability of the study findings. Collaboration with other health-care professionals and stakeholders is also important to enhance the relevance and impact of the research.

Phases of the Research Process

Nursing research is conducted in five phases (Brunt & Morris, 2023):

1. Conceptual phase
2. Design and planning phase

3. Empirical phase
4. Analytic phase
5. Dissemination phase

Phase 1: Conceptual

The conceptual phase in nursing research involves the identification and development of research ideas, hypotheses, and theoretical frameworks. It sets the foundation for the entire research process. At the start of a research project, researchers typically formulate a research question or hypothesis. They use skills such as creativity, deductive reasoning, insight, as well as a solid grounding in previous research on the topic of interest. Table 1.4 lists important issues that nursing researchers consider when developing a research question:

Considerations	Examples
Substantive issues	Is the research question significant?
Clinical issues	Could the findings be useful in clinical practice?
Methodological issues	How can the study be designed to yield high-quality evidence?
Practical issues	Are adequate resources available to do the study?
Ethical issues	Can this question be addressed without committing ethical transgressions?

TABLE 1.4 Important Considerations for Nursing Research

To organize the goals of a research project, nursing researchers often use **PICOT**, an acronym that reminds researchers of five key elements of an effective question. Table 1.5 lists these five elements and gives examples relevant to nursing research. The PICOT question is versatile, allowing assessment across different clinical domains like intervention, diagnosis, etiology, prevention, prognosis or prediction, quality of life, or therapy. When in the research phase, it's crucial to craft the PICOT question effectively, aiming for an evidence-based recommendation that enhances patient care and outcomes as the result.

PICOT Format	Examples
P = Population or Problem	Who are the patients to be studied? What characteristics are we focusing on (e.g., age, race, gender, disease, health status)? What problem is being addressed (e.g., mortality, morbidity, compliance, satisfaction)?
I = Intervention	What specific intervention (e.g., therapy, medication, educational approach) will be implemented?
C = Comparison	What alternative(s) will we compare the intervention to (e.g., placebo, no intervention, different medication)?
O = Outcome	What will be measured and how? What is the identified goal (e.g., fewer symptoms, increased satisfaction, reduced mortality)?
T = Time Frame	How long will the intervention be implemented and data collected?

TABLE 1.5 PICOT (Brunt & Morris 2023)

Phase 2: Design and Planning

During this phase of a study, researchers brainstorm and determine which method they will use for their study. From a broad perspective, research methods are the techniques researchers use to gather and analyze information

relevant to a research question or topic. The goal of this process is to limit errors that could contaminate conclusions or invalidate findings. An example of an error that could contaminate or invalidate nursing research is selection bias. This occurs when there is a systematic difference between the characteristics of the group that is selected for the study and the larger population from which it is drawn.

For example, imagine a study in which researchers want to investigate the effectiveness of a new nursing intervention for managing pain in postoperative patients. If the researchers only include patients who voluntarily agree to participate in the study, there might be a bias toward individuals who are more willing or motivated to try new interventions. This selection bias could lead to overestimating the effectiveness of the intervention because the sample may not be representative of the entire population of postoperative patients. Addressing and minimizing such biases are crucial in the methodological planning phase of nursing research to ensure that the study's findings accurately reflect the broader population and can be applied more reliably to real-world clinical settings.

Phase 3: Empirical

During the next phase, researchers collect data. Collectively, the pieces of gathered information are referred to as a data set. Quantitative data include numbers and other objectively measurable information; qualitative data consist of subjective descriptions of observations or experiences. The empirical phase is often the most time-consuming part of the investigation; it is conducted in accordance with the data collection plan (where, when, and how the data will be collected) that was determined during the planning phase.

Phase 4: Analytic

The analytic phase must be done in a processed, orderly manner to enable researchers to discern and validate relevant patterns and relationships in the data. After researchers have analyzed the data, they determine how the study's findings can best be used in clinical practice. This is when the researchers come full circle to answer the research question from phase 1. However, research is not complete until the results are disseminated in the final phase.

Phase 5: Dissemination

In the final phase of a study, the researchers communicate their findings so others can use the information in their clinical practice. This phase also allows other researchers to try to replicate the study to see if they obtain similar results. Researchers typically communicate by publishing a research report so others can easily access it. The most common types of research reports are theses and dissertations, books, presentations, and journal articles.

Many studies do not have a direct impact on clinical practice; ideally, however, the concluding step of research is to plan for its application to the clinical setting. Even when researchers are unable to implement such a plan, they can still contribute to the process by developing recommendations on how practicing nurses might someday implement the findings. Of course, many studies produce inconclusive results or even data that contradict the hypothesis. These findings are useful, too! They can help guide future researchers to identify flaws in the study or to develop better hypotheses that are supported by data.

Roles and Responsibilities in Nursing Research

Nursing researchers strive to promote participant safety and well-being during a study. They develop plans to ensure the study runs smoothly while keeping the participants fully informed. Researchers also rely on clinical nurses to put their findings into action. The efforts, successes, and failures of practicing nurses often lay the groundwork for future research. Working in tandem, researchers and clinicians continue to close the gap between theory and knowledge-based practice.

Ethics and the Research Process

Researchers often face ethical dilemmas when designing studies. Institutional review boards exist to ensure that studies are designed ethically, with the welfare of participants foremost in mind. The three major ethical principles incorporated into most research guidelines are beneficence, justice, and respect for human dignity. Recall that beneficence is the principle of doing good while also protecting the participants from physical and psychological harm and exploitation (nonmaleficence). Justice includes the right to fair and equitable treatment and to privacy. Privacy may be maintained through **anonymity**, wherein the researchers do not know each participant's identity, or through formal confidentiality procedures that safeguard the information provided by the participants.

Respect for human dignity ensures the participants' right to autonomy, also known as self-determination, which

means they have the freedom to control their own activities, including their choice to participate in the study. To ensure this, at the beginning of the study, the researchers provide each participant with a **full disclosure** that completely describes the study, including the risks and possible benefits. Each participant also signs an **informed consent** indicating they have a thorough understanding of the study and agree to voluntary and informed participation.

Once all data have been collected, researchers sometimes offer debriefing sessions for the participants. This process provides the participants an opportunity to learn about the study, ask questions, and voice any complaints.

Application of Nursing Research and EBP in Practice

EBP and nursing research have similarities, but they are not the same. The main difference between the two is their purpose. The purpose of research in nursing is to evaluate current knowledge and theories to formulate better nursing practices for improved patient outcomes. The purpose of EBP in nursing is to use the evidence from research to make informed decisions regarding patient care and outcomes. EBP is vital to providing the highest quality of patient care and safety. As defined by Melnyk and Fineout-Overholt (2023), EBP typically includes seven steps:

1. encouraging a spirit of inquiry or curiosity
2. asking questions
3. searching for evidence
4. appraising the evidence
5. integrating the evidence into practice
6. evaluating outcomes of the practice change
7. sharing the results

Examples of Nursing Research

Nurses are firsthand observers while providing patient care, enabling them to directly assess and document processes and ideas that could be improved through further investigation. The topics nurses may choose to research are endless; they are the drivers of evidence-based knowledge to promote improved patient outcomes. Here are just a few examples of the countless possible topics for nursing research:

- adapting nursing in a digital era
- causes and prevalence of stress in nurses
- ethics related to artificial hydration and nutrition
- personalized diets for older adults to promote healthy aging
- strategies for raising awareness of cancer-causing air pollution
- the opioid crisis and its social impacts

Regardless of the topic, the process begins with developing a question (often using the PICOT format), choosing the design for your research, and setting clear goals (Riva et al., 2012).

Examples of EBP in Nursing

EBP is intended to promote positive outcomes through shared decision-making, but another essential goal is to prevent complications. These achievements, in turn, help reduce health-care costs, improve patient satisfaction (which further improves reimbursement rates), and reduce the demand for health-care resources, enabling organizations to reallocate resources to other areas where they will be more effective. Table 1.6 lists some examples of EBP in nursing.

Example	Outcome
Elevating the head of a patient's bed between 30° and 45°	Supports the airway and reduces the risk of aspiration
Turning and repositioning a patient every 2 hours	Helps to maintain clean, dry skin and prevent skin breakdown

TABLE 1.6 Examples of EBP in Nursing

Example	Outcome
Wearing personal protective equipment as necessary, using proper hand hygiene, and maintaining a clean environment	Prevents hospital-acquired infections and reduces the spread of other infections
Administering oxygen when treating chronic obstructive pulmonary disease	Improves the survival rate by reducing the risk of hypoxia (a deficiency of oxygen reaching the body tissues) and organ failure

TABLE 1.6 Examples of EBP in Nursing

Quality Improvement

The framework used to improve patient care and outcomes in a systematic manner is called **quality improvement**. This is accomplished with standardized processes and structures to reduce variation and achieve predictable results to improve patient outcomes. Processes might include standard protocols for operating procedures, education, and training. Structures might include up-to-date technology and a culture of quality that ensures everyone is working together to deliver quality health care for patients. A QI mindset encourages providers to become leaders in researching and delivering positive changes and improvements in every component of the health-care system.

The QI process involves a collaborative effort from various stakeholders within a health-care setting, including health-care professionals such as physicians, nurses, administrators, and support staff. Nurses play a crucial role in the QI process, contributing their frontline experience and expertise in patient care. They actively participate in identifying areas for improvement, implementing changes, and monitoring outcomes. Nurses are instrumental in ensuring that quality standards are met, patient safety is prioritized, and EBPs are integrated into daily care.

Models for QI

When undertaking a QI project, it is important to use a model that will guide the project and provide feedback related to progress. Two common QI models used in nursing originated in the manufacturing industry: the Six Sigma model and the Lean Model. The Six Sigma model was created by Motorola. Its main goals are to decrease variation and defects in products (Earlam, 2016). The Lean model was created by Toyota. Its main goals are to eliminate waste and improve efficiency so tall work adds value (John's Hopkins Nursing Center for Nursing Inquiry, 2022).

A third QI model was developed specifically for health care by Associates for Process Improvement in partnership with the Institute for Healthcare Improvement (IHI). The resulting Model for Improvement was created by expanding the plan-do-study-act (PDSA) cycle. The PDSA cycle is a continuous process that works to improve quality by following the steps of the scientific process: making a hypothesis (plan), testing the hypothesis (do), examining the results (study), and reporting the results (act).

Phase 1

The Model for Improvement is divided into two phases. Phase 1 begins by asking three pertinent questions:

1. What are you trying to accomplish?
2. How will you know that a change is an improvement?
3. What changes can you make that will result in improvement?

These questions help structure the phase, which consists of setting aims, establishing measures, and selecting an intervention (changes).When setting aims, or goals, it helps to use the SMART format:

- *Specific:* Make goals straightforward, stating specifically what you want to happen.
- *Measurable:* Choose goals with outcomes that can be measured to assess your progress.
- *Achievable:* Ensure goals are attainable and not overambitious.
- *Relevant:* Choose goals that align with those of your organization.
- *Time-bound:* Set a reasonable time frame in which to attain each goal.

Establishing measures helps the team determine if a change results in a tangible improvement. There are four common types of QI metrics:

- Balancing metrics involve assessing unintended consequences or potential negative impacts of QI initiatives. Although the primary focus is on improving specific aspects of care, it's essential to monitor for any adverse effects on other areas. Balancing metrics help prevent unintended harm and ensure a balanced approach to QI efforts.
- Outcome metrics are used to assess the results or impacts of health-care processes or interventions. Examples include patient outcomes such as mortality rates, readmission rates, complication rates, and patient satisfaction scores. Outcome metrics provide insights into the overall effectiveness of health-care practices.
- Process metrics focus on the steps or activities involved in delivering health care. They measure the efficiency, reliability, and adherence to established protocols. Examples include the time it takes to complete a specific procedure, compliance with evidence-based guidelines, and adherence to safety protocols.
- Structure metrics assess the organizational and environmental factors that can influence the delivery of healthcare. These may include the availability of resources, staffing levels, infrastructure, and the implementation of best practices. Monitoring structure metrics helps ensure the necessary components are in place to support high-quality care.

For example, suppose a hospital wants to decrease its rates of hand-borne infections. The QI team might use the *structure* measure of the availability of hand-sanitizer pumps, the *process* measure of handwashing compliance rates, the *outcome* measure of hospital-acquired infection rates, and the *imbalance* measure of skin breakdown among the staff.

The final step in phase 1 is selecting an intervention or solution. This is accomplished by determining the cause of a particular problem. QI teams do this by conducting a root cause analysis. By determining the root cause of a problem, you can more easily determine the appropriate interventions.

Phase 2

The second phase of the Model for Improvement is to test the intervention using the PDSA cycle:

- Plan: Identify stakeholders—anyone who is key to the project's success or otherwise invested in it—and begin building the implementation team. This should include management and clinical staff as well as patients and their families. It's also important to know which stakeholders, if any, may hinder the advancement of the project, to determine how frequently to engage with everyone. For example, a nondisclosure or identification of a conflict of interest can halt a study.
- Do: Take the necessary time to set the plan in motion, implementing the intervention while collecting and documenting data relevant to the project's success.
- Study: Analyze the data and compare the actual results to the initial hypothesis.
- Act: Take the necessary time to act on what was learned. Did it work? Do you need to adapt changes to begin a second PDSA cycle because the first approach didn't quite attain your goal? Or do you need to abandon the intervention because you observed no improvement or a worse outcome?

Attributes of QI

The goal of QI is to adopt a reputable model to guide a project while collecting and analyzing data and testing the effects of interventions. Implementing QI is vital to any organization that seeks to provide quality care and improve efficiency, safety, and patient outcomes. Here are some recent examples of QI by health-care organizations (Health Catalyst Editors, 2022):

- Allina Health implemented an initiative for pharmacist-led medication therapy management that reduced the cost of care and improved patient outcomes.
- Mission Health in North Carolina began using a data-driven approach to promote early sepsis identification and standardize the treatment of sepsis.
- UnityPoint Health established a prioritization and implementation approach to improve outcomes that produced the following results: (1) the deployment of interventions in sepsis alerts, order sets, and other clinical support tools resulted in variable costs being reduced; (2) the reductions in level of service resulted in patients returning home sooner; and (3) there was an increase in sepsis screenings being completed and an increase in sepsis order sets being used in the emergency department.

1.5 Health-Care Delivery Systems

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the impact that various service providers and agencies have on health-care systems
- Differentiate between the types of preventive services available in health-care systems
- Identify factors affecting health-care delivery

The **health-care delivery system** consists of all the individuals and organizations collectively responsible for providing and overseeing health care in an area. These components include providers (e.g., physicians, nurses, technicians), facilities (e.g., hospitals, private practices), and insurers, all of which operate in a variety of configurations, from independent practices to groups and networks. They may be in the public sector or private sector; they may be for-profit or not-for-profit organizations; and they may emphasize primary, secondary, or tertiary prevention. The system also includes regulators from state and federal agencies.

Health-care delivery systems change as the needs and expectations of populations change. Systemic changes are influenced by factors such as shifting population demographics, an increase of chronic illnesses or disabilities, a heightened focus on social and economic conditions, and technological advances.

Types of Health-Care Services and Agencies

Health care is provided by many different providers and agencies working in a variety of settings, such as hospitals, skilled nursing facilities, clinics, assisted living facilities, and in-home care. Agencies that provide in-home care may offer a range of services, such as physical and occupational therapy, palliative care, hospice, and infusion therapy. A variety of community services may also be available, including public health departments, physical therapy centers, dialysis centers, senior centers, and adult day care centers.

Although access to health insurance is a determinant to access routine health care, government agencies and programs exist to help low-income populations access services as well. These include Medicare, Medicaid, the Department of Health and Human Services, the Department of Family and Children Services, the Department of Behavioral Health and Developmental Disabilities, and the Area Agency on Aging, to name a few. There are also Medicaid Waiver Programs to help with in-home care services or to assist with accommodation in personal care and group homes. The names of these agencies may vary from state to state. Patients often require the medical community to provide guidance, education, and support on an individual basis to access all the services available to them.

Inpatient Services

Hospitals provide inpatient services for patients who are acutely ill, experiencing complications from a disease, or undergoing or recovering from a surgical procedure. Additionally, some hospitals provide specialized care. For example, there are children's hospitals, hospitals with cardiac care units, cancer centers, burn units, and many other specialty centers. Even hospitals that provide the same inpatient services may be structured in a variety of ways. Some hospitals are-for profit entities, whereas others also have a nonprofit component. Additionally, states designate certain hospitals as providers of care for the area's low-income population (indigent care).

Subacute inpatient settings are for patients who still need skilled care but are no longer sick enough to remain in the hospital. This type of care is provided in skilled nursing facilities (sometimes called nursing homes), as well as in specialty hospitals for patients who require certain services, such as those receiving ventilatory support. Another type of subacute setting is independent rehabilitation centers, which may be housed within hospitals or nursing homes. There are also specialized rehabilitation centers for conditions such as brain injuries and in Veterans Administration hospitals, where military veterans may be recovering from spinal cord injuries or learning to live with blindness.

Outpatient Services

Many people who live at home still need outpatient, or ambulatory, care. This care, which provides employment opportunities for many health-care workers outside of hospitals, includes diagnostic, observation, treatment, and rehabilitation services. Examples of outpatient services include

- acute care clinics

- centers for chemotherapy and radiation treatment
- dialysis centers
- imaging centers for computed tomography scans, magnetic resonance imagining, ultrasounds, mammograms, and other types of scans
- laboratories for processing outpatient blood samples
- outpatient surgery centers
- settings for physical and occupational therapy
- wound care centers

Post-Acute Services

Patients who are well enough not to require inpatient care as they recover from an acute condition may benefit from a variety of post-acute services in the community. The goal of post-acute care is to increase a person's ability to care for themselves and to promote as much independence as possible. Outpatient post-acute services are offered by many providers and include the following:

- Assisted living facilities provide medical oversight for medically frail persons who can no longer live safely at home.
- Home health agencies provide skilled care as well as physical and occupation therapy for patients in their home.
- Hospice agencies support patients with a prognosis of 6 months or less to live.
- Infusion therapy agencies deliver intravenous medications or fluids to patients who need them.
- Memory care facilities assist individuals at risk of wandering, such as those with diagnoses such as Alzheimer disease and other types of dementia.
- Personal care and group homes provide medical oversight in a residential, family-type environment and tend to be less expensive than traditional assisted living facilities. For low-income individuals, Medicaid waivers can assist with this expense.
- Rehabilitation centers provide physical and occupational therapy to improve strength and mobility for people recovering from illness, injury, or stroke.

Adult Care Services

Every community includes people who require assistance to stay in their homes. Community-based services that can provide this help include in-home care and adult day care.

In-home care is different from home health care. In-home agencies provide a care assistant: some are certified nursing assistants and personal care aides, others are individually trained by the agency they work for. These aides help with bathing, dressing, grooming, and light household chores and errands. The care is supervised by a nurse in the agency, but no skilled care is involved. Aside from private pay, different types of funding are available that vary from state to state through Medicaid and associated waiver programs. Additional programs are available for individuals with developmental disabilities, veterans, and other special populations. The Area Agency on Aging is a good resource for seniors to find and gain access to community services.

Adult day care centers provide respite for caregivers, enabling them to continue working or otherwise live their life while their loved one is being cared for. Unlike traditional senior centers, where relatively healthy individuals can socialize, exercise, and take classes, adult day care centers are for individuals who have physical and cognitive conditions that require supervision and a higher level of need. Research has shown that these services have a positive impact not only on patients but also their caregivers (Kiger, 2017; Ellen et al., 2017).

Public Health

Public health agencies, through government funding, shoulder much of the responsibility of providing care to the underserved, the uninsured, and other at-risk populations. The goal of public health is the prevention of premature death and disability through measurable improvements in health status and quality of life. To ensure success, political figures may need to be better trained in public health so that legislation and policies go beyond the science to also consider how economic, ideological, and personal factors can affect the needs of people in the public health system.

The decision-making process within political systems at the national, state, and local levels is the vehicle through which public health initiatives and delivery systems are funded. Health is a key determinant of economic vitality, but

it is dependent on the effectiveness of health-care delivery systems. To sustain economic vitality and development, the workforce requires affordable health care as well as affordable housing, transportation, and other social and economic determinants. Thus, the outcomes related to public health are directly related to and reliant on the decisions of elected officials, many of whom do not necessarily see how their decisions affect the delivery of public health. Facilitating constructive dialog between public health advocates and legislators could lead to sustainable improvements to public health policies and programs.

Types of Preventive Services

Wherever an individual or organization is situated within the health-care delivery system, their ultimate goal is to promote quality care and improved outcomes by meeting each patient where they are. Depending on the progression of their particular disease or illness, a patient may seek any of three main types of preventive services: primary, secondary, or tertiary.

Primary Prevention

The goal of **primary prevention** is to prevent disease before it occurs. This can be accomplished by making lifestyle changes to correct unhealthy choices or unsafe behaviors, preventing exposure to environmental hazards, and taking measures to increase resistance to disease or injury. Strategies for primary prevention include

- becoming more knowledgeable about the signs and symptoms of and risk factors for relevant diseases or illnesses within one's family, such as diabetes, high blood pressure, stroke, and pulmonary and heart-related diseases
- choosing to be immunized against infectious diseases
- choosing to eat healthier foods
- making better, more informed choices regarding exercise, diet, and other behaviors
- supporting enforcement to mandate safe practices such as wearing seatbelts
- supporting legislation to control the use of hazardous environmental products

Vaccination programs to prevent infectious diseases, public health campaigns promoting healthy lifestyles and behaviors, and education on the importance of regular exercise and a balanced diet all fall under primary prevention. Community health centers, schools, workplaces, and public health departments are common physical locations for primary prevention efforts.

Secondary Prevention

The goal of **secondary prevention** is to promote early diagnosis and treatment to slow the progression of a disease or injury and reduce its long-term impacts. This process begins with early detection and incorporates strategies such as:

- modifying work for injured or ill workers to enable them to return to work safely
- regularly screening for cancers (e.g., mammograms to screen for breast cancer; oral screenings to detect mouth cancers)
- screening for high blood pressure
- taking low doses of aspirin daily to prevent a stroke

Secondary prevention often occurs in health-care facilities and clinical settings. Examples include hospitals, clinics, diagnostic centers, and physician offices, where screenings, health check-ups, and early detection activities are conducted.

Tertiary Prevention

The goal of **tertiary prevention** is to decrease the impact of an ongoing illness or injury (e.g., educating people about how to manage their long-term condition). Effective tertiary treatment can help patients regain mobility and bodily function and maintain a positive quality of life. Examples include

- chronic disease management programs (e.g., diabetes, depression) to slow the disease's progress and develop modifications to promote quality of life
- palliative care to reduce and relieve symptoms of chronic illness
- stroke rehabilitation programs
- vocational rehabilitation programs to retrain injured or ill workers for new jobs

Tertiary prevention is frequently implemented in rehabilitation and specialized care facilities. Hospitals with rehabilitation units, outpatient rehabilitation centers, and chronic disease management clinics are common physical locations for tertiary prevention efforts. Support groups and counseling services may also be located in community centers or health-care institutions.

Factors Affecting Health-Care Delivery

As previously discussed, SDOH are the economic and social factors that affect health outcomes. These nonmedical factors (e.g., where individuals are born, live, and age) have a direct impact on daily life and are directly influenced by larger forces such as economic policies, social norms, development agendas, and political systems.

How effectively a health-care system addresses SDOH plays a major role in whether that system promotes **health equity**, giving everyone the same fair opportunities to attain the highest level of health outcomes. In contrast, systems that fail to adequately address SDOH tend to be rife with **health inequities**, or disparities. In fact, research indicates that SDOH can have a greater impact on health outcomes than health care or lifestyle choices can.

Patient Demographics

Population demographics directly influence the need for health care and its delivery. In fact, the effectiveness of traditional health-care delivery in the United States has been greatly affected by changing demographics, necessitating innovative changes throughout the health-care delivery system (Vespa et al., 2020). Not only is the US population increasing but its composition is changing due to a variety of factors, including immigration and social trends. Other factors that affect patient demographics are birth and death rates, socioeconomic status, cultural diversity, the relative sizes of different age groups, the number of people living in urban versus rural communities, and the number of homeless people versus the number of families in an area. Table 1.7 summarizes some of the main ways that US demographics are changing.

Category	Major Changes
Age	By 2034, older adults are projected to outnumber children for the first time in US history. One in every five Americans is projected to be of retirement age.
Diversity	By 2028, the foreign-born share of the US population is projected to be higher than any time since 1850. By 2045, non-Hispanic White people are no longer projected to make up the majority of the US population. By 2060, one in three Americans (32 percent of the population) is projected to be a race other than White, and the number of people who identify as two or more races is projected to grow some 200 percent.
Growth	During the 2020s, the US population is projected to grow by about 0.7 percent annually. By 2030, immigration is projected to become the primary driver of population growth.

TABLE 1.7 US Demographic Trends (US Census Bureau, 2020)

Beyond 2030, the US population is projected to grow slowly, to age considerably, and to become more racially and ethnically diverse.

Access to Health Care and Insurance

Although access to health care is an important determinant of health, having health insurance is even more important. Health insurance is an essential factor to accessing routine health care, especially preventive care, and it is directly correlated with better health outcomes. It ensures a regular source of care with the most appropriate use of health services, which, in turn, improves access to disease screening, early detection, and care for chronic and acute conditions.

People without health insurance are at an increased risk of going without health care. This is particularly damaging for children, because lack of access to health care promotes poor health and decreased productivity throughout their lives and increases the risk of premature death.

Advances in Technology

Many advances in technology have resulted in changes within the health-care delivery system. The introduction and spread of **telehealth**, sometimes called e-health or m-health (mobile health), has enabled patients to access health-care services remotely, though personal computers, tablets, or smartphones, rather than in person. Telehealth has been exceptionally helpful in remote areas where access to health-care facilities is limited. Goals of telehealth include

- facilitating patients' self-management of their care
- improving communication and coordination of care among all members of the health-care team
- keeping people safe from infectious diseases such as COVID-19
- making access to health care easier for those with limited mobility or transportation
- offering primary care and specialist care simultaneously (e.g., through an online conference call or meeting)

Additionally, through a range of innovations such as remote monitoring, patient portals, personal health apps, and accessible personal health records, technology has brought about much-needed changes in the health delivery system to improve patient outcomes (Nursing informatics n.d.). Rapid, reliable communication is one of the most important aspects contributing to patient safety, and the aforementioned innovations have greatly improved turnaround times for physician orders and enabled everyone on the care team to access EHRs more quickly, resulting in reduced medical errors, fewer delays to patient care, and lower costs of health care.

Triple-Aim Initiative

The IHI has developed a framework intended to optimize the performance of health-care delivery systems by pursuing three dimensions simultaneously: (1) improving the patient experience of care, (2) improving the health of the population, and (3) improving health equity by reducing the per capita cost of health care.

IHI calls this initiative "Triple Aim." Triple Aim recognizes that chronic health problems resulting from an aging population with increased longevity have become a global challenge and created new demands on medical and social services. Though it broadly focuses on health at the community level, Triple Aim requires systemic, ambitious improvement at all levels of the system (IHI, n.d.).

The IHI believes communities and organizations that successfully implement Triple Aim will have healthier populations because they will identify problems and solutions upstream, before they require acute health-care services; this will alleviate the need for complex care coordination and decrease the burden of illness. Furthermore, stabilizing or even reducing the per capita cost of care will allow private providers to be more competitive, relieving the pressure on publicly funded health-care budgets and giving communities greater flexibility to invest in SDOH such as schools and the environments where people live and work.

The Institute for Healthcare Improvement (https://openstax.org/r/77ihitriple) provides an in-depth look at the IHI Triple Aim Initiative.

1.6 Systems-Based Practice

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define systems-based practice
- Evaluate the role of the nurse in the delivery of systems-based practice
- Discuss the role of interdisciplinary teams in health-care delivery

A system can be defined as "a collection of interdependent elements that interact to achieve a common purpose" (Nolan, 1998). In **systems-based practice** (SBP), a clinician considers the multiple systems that are involved in a patient's condition and uses evidence about their interactions to develop a treatment plan that incorporates the intricacies involved in the patient's care. It takes time to acquire knowledge about all the relevant systems and to acclimate to systems-based thinking. The clinician who achieves this can use the skill to determine the interventions most likely to address all the patient's issues. (Johnson et al., 2008; Marshfield Clinic, n.d.;

HealthStream, 2021)

What Is Systems-Based Practice?

SBP focuses on the broader context of patient care, including the recognition that multiple layers make up the health-care system. These layers include

- consumers of care (patients and their families)
- delivery systems (hospitals, physician networks, drug and technology companies, community resources)
- insurers of care (private companies, Medicare, Medicaid)
- providers of care (physicians, nurses, health-care teams that provide direct care)
- purchasers of care (individuals, employers, governments)

Recognition of establishments such as the structures, systems, rules and regulations, payor sources, as well as the impacts of each to patient care provides a comprehensive understanding of how these entities need to work together as a whole and why their collaboration is important. Examples of SBP in health care include

- approaching identified problems with the goal of solving them versus relying on a workaround
- developing insight into the legal, political, regulatory, and economic factors that influence the delivery of health care
- having an understanding of cost containment, resource allocation, patient advocacy, and interdisciplinary collaboration in the delivery of quality care
- recognizing the outcome of individual and group actions on quality care and patient safety
- understanding how each different care setting works together for patients
- working in interdisciplinary teams to improve patient outcomes

SBP assumes that each patient exists in a context of interconnecting, interdependent systems. These systems may be large or small, complex or relatively simple, The ability to recognize each system and understand how they work together and fit into the overall structure is essential to promoting the quality of patient care while also reducing errors.

Microsystems

Although health-care providers work within a complex system, the area in which they conduct their daily work is considered a **microsystem**. Microsystems coexist with other microsystems that are typically embedded within a larger health system or organization. For a small-scale example, consider a surgical team, a cardiology unit, and a dialysis/renal unit: these are all microsystems housed inside a larger macro-organization: the hospital. Each microsystem has a common core of elements, including a focused type of care, a defined patient population, skilled staff trained to provide the care processes, and the needed information and technology to support these processes. Effective microsystems evolve over time and can foster collaboration.

Macrosystems

A **macrosystem** is the culture or society that surrounds smaller systems and gives them structure. Its components include laws, rules and regulations, government agencies, political systems, social policies, and educational resources, all of which have a direct impact on health care, public health, health equity, and the systems in which health care is delivered. SBP incorporates the multiple layers (microsystems) that make up health care (a macrosystem) into the context of quality patient care, patient safety, and health outcomes (Sawatzky et al., 2021).

Role of the Nurse in SBP

Nurses are a key component of an effective SBP strategy. Effective nurses recognize how they function within their respective microsystem as well as how their actions affect each aspect of the macrosystem in which they work. They are responsive to the complexities of these systems and able to call on all the other resources available to them. They can determine the cost of care, analyze risks and benefits, advocate for quality patient care, work within an interdisciplinary team, identify system errors, and develop and implement system solutions.

It is also important to note that systems can be improved upon. As frontline care providers, nurses can effect change because they observe firsthand the impacts of various systems on delivering patient care. These observations can be used to bring about changes to improve patient safety and quality care, which are the goals of

SBP.

Role of the Interdisciplinary Team

SBP applies to all areas of health care. Mastering SBP enables a clinician to have a thorough understanding of every direction to which care can lead as well as what is optimal for each patient.

SBP also encourages providers to pay attention to health equity and work together to improve the delivery of care. Effective teamwork is essential to developing competence in SBP. Bringing together team members with specialized skills and training from a variety of disciplines improves both the delivery of care and outcomes for each patient. By implementing interdisciplinary patient rounds, team members can brainstorm solutions to identified problems and coordinate their implementation.

For example, consider the newer routine of having grand rounds on a unit each day at a specific time. Several members of the interdisciplinary team come together to review the needs of the patient and the health plan. The team often consists of the patient's nurse, charge nurse, house supervisor, physician, pharmacist, social worker, physical therapist, and dietitian. By working together, the team begins to see how each team member contributes a valuable perspective to the care for each patient, enabling the team to develop holistic approaches that enhance the delivery of PCC. Communication among all team members involved in the patient's care also enables the team to have a better understanding of the patient's needs and expectations.

1.7 Technology and Informatics

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the importance of informatics in nursing
- Explain how technology has affected nursing education and practice
- Explain the impact of the Health Insurance Portability and Accountability Act (HIPAA) on delivering care

As technology has evolved in health care, nurses have used these advances to improve patient care in numerous ways. The huge leaps in health-care technology over the past few decades have resulted in invaluable tools. Examples include the use of medical devices and mobile health apps to help monitor patient care, and the use of EHRs to document and track patient's medications, tests, laboratory results, and orders. These technological advancements, in conjunction with the field of nursing informatics, have promoted the efficiency, effectiveness, and safety of patient care.

Informatics

The specialty that uses information and technology to improve the efficiency of health care and its delivery is called **nursing informatics**. This field of nursing focuses on methods of storing the three building blocks of communication as well as wisdom in computer programs and software so they can be analyzed and used to support improvements in health care (Nursing informatics, n.d.).

Let's look at how these four components—data, information, knowledge, and wisdom—breakdown.

- The term *data* refers to raw, unprocessed facts or observations. In nursing, data can be objective and measurable information collected during patient assessments, such as vital signs (e.g., heart rate, blood pressure, temperature) or laboratory values. Examples include numeric values representing a patient's blood glucose levels or a list of recorded symptoms (e.g., pain scale scores).
- Information is processed and organized data that provides context and meaning. It transforms raw data into a structured form, facilitating understanding. In nursing, information may involve interpreting and contextualizing data to support decision-making. For example, aggregated vital signs data, over time, enable providers to detect trends and patterns that help identify changes in a patient's condition.
- Knowledge involves the synthesis and interpretation of information to derive insights and conclusions. It reflects a deeper understanding and application of information in specific contexts. In nursing, knowledge integrates information to guide clinical reasoning and decision-making. For example, a nurse may apply information from a patient's medical history and about current symptoms and responses to interventions to formulate a comprehensive care plan.

- Wisdom is the ability to make sound judgments and decisions based on a deep understanding of situations. In nursing informatics, wisdom goes beyond knowledge and involves the application of experience and ethical considerations to guide actions and outcomes. An example is making informed decisions about patient care that not only consider clinical data and knowledge but also incorporate ethical principles, patient preferences, and long-term implications for well-rounded and compassionate care.

In nursing informatics, the progression from data to wisdom reflects the evolution of information into actionable insights, ultimately contributing to improved patient outcomes and the overall quality of nursing practice.

The Importance of Informatics

Nursing informatics is essential in helping nurses make informed decisions. Nurses have always used data, information, and knowledge in their daily practice. With the advancement of nursing informatics, however, these components are immediately available for each patient to assist each nurse in making sound decisions about care and effectively communicating these decisions—and their outcomes—with the interdisciplinary team. In addition to developing communication and information technology, nursing informaticists also work as educators, researchers, and software engineers to develop evidence-based policies and procedures for organizational use in the nurse's clinical practice.

Application to Professional Nursing

Nurses need quick access to each patient's medical history, medication lists, laboratory values, and imaging results, as well as to notes from physicians and other members of the interdisciplinary team. All this information gives a comprehensive picture of a patient's clinical status, enabling the nurse to make informed decisions to improve patient outcomes and to effectively communicate with all members of the interdisciplinary team. Communication is, without doubt, one of the most important components of patient safety. Nursing informatics has been instrumental in developing and advancing the capabilities of EHRs (discussed later in this module) and the ability of physicians to immediately input digital orders for patient care. This has effectively reduced medical errors, patient care delays, and health care costs.

Technology in Nursing Education

Throughout one's nursing education, it's important to stay abreast of the advancements in technology. This enables nurses to remain in sync with the industry's expectations for health-care delivery and with patients' expectations for health outcomes. More fundamentally, technology has come to play a vital role in nursing education, from learning in a classroom (and assessing that learning) to conducting research in the field. Even what counts as a "classroom" has evolved as technological advances have enabled many educational institutions to move to online platforms.

A particularly important advance in technology for nursing education has been the development of high-tech simulation laboratories ("sim labs") using manikins that closely resemble real people. The manikins are programmed to simulate real-life patients and clinical situations; for example, they can talk and blink, their pupils dilate, and their "heart" beats. This enables nursing students to work in an environment that parallels the real world. After each sim lab experience, students can debrief, talking through what went right and wrong, which further promotes their knowledge and critical thinking skills. Working through simulated scenarios during nursing school better prepares nursing students for their entry into high-pressure clinical situations. After graduation, nurses may still use simulations to renew certification skills such as cardiopulmonary resuscitation.

Technology in Nursing Practice

New medical technologies also make nurses' lives easier when delivering care and, when used properly, they can also improve patient safety and outcomes. Today, a variety of technologies help nurses complete their daily routines while decreasing human mistakes and errors—especially important when working long hours with a heavy caseload. Technology will never replace the human experience, which is crucial for positive patient outcomes, but with the right balance, it can help ease the demands associated with direct patient care. Examples of technologies that facilitate routine nursing tasks include

- automated intravenous infusion pumps
- centralized command centers
- EHRs
- portable monitors

- smart beds
- telehealth and apps
- wearable devices

Technology has also enabled the use of e-prescribing, enabling a prescriber to electronically send an accurate, error-free, and understandable prescription directly to a pharmacy from the point of care. This has become an important element in improving the quality of patient care.

Electronic Health Records

EHRs provide immediate access to patient information, enabling the nurse to access a patient's medical history, medications, and laboratory and other test results to promote sound decision-making. EHRs also promote effective communication between the providers within the interdisciplinary teams, minimizing delays in treatment, reducing errors, and improving health-care costs.

In 2009, the Health Information Technology for Economic and Clinical Health (HITECH) Act was signed into law. HITECH's main goal was to encourage the adoption of EHRs by creating a financial incentive for providers to transition from paper to electronic records. In addition, HITECH strengthened existing regulations to ensure electronic data remain secure. As a result, many providers have implemented the use of portals for patients to access and even record or supplement their own health data (US Department of Health and Human Services, 2017; Alder, 2023).

The Health Insurance Portability and Accountability Act

The **Health Insurance Portability and Accountability Act (HIPAA)** became federal law in 1996. It created national standards to protect patient privacy, primarily by prohibiting the disclosure of health information without a patient's consent or knowledge. It has two components: the HIPAA Privacy Rule and the HIPAA Security Rule.

The HIPAA Privacy Rule provides standards relating to the use and disclosure of an individual's health information, which is known as "protected health information" (PHI), by "covered entities" that are subject to this rule. The Privacy Rule also provides standards for individuals' rights to understand and control how their health information is used. The covered entities include health-care providers and practices, health plan providers, health-care clearing houses, and business associates such as billing and claims processors, data analysis providers, and utilization review entities. The primary goal of the Privacy Rule is to protect individuals' health information while also enabling the flow of the health information needed to provide quality care (Alder, 2023).

The HIPAA Security Rule protects public health information, which is a subset of information covered by the Privacy Rule. This subset includes individually identifiable health information that a covered entity creates, receives, maintains, or transmits in electronic form (known as electronic protected health information [e-PHI]); it does not apply to PHI transmitted orally or in writing. To ensure compliance with the Security Rule, all covered entities must ensure confidentiality, maintain integrity, and provide accessibility to all e-PHI; be aware of and safeguard against anticipated threats to the security of e-PHI; provide protection against any anticipated impermissible uses or disclosure not permitted by the Privacy Rule; and ensure compliance by their employees (Alder, 2023).

Summary

1.1 Professional Nursing Practice

- Medical-surgical nurses provide care for adult patients of all ages who are preparing for or recovering from surgery. They also care for patients with an exacerbation of symptoms or complications related to a variety of long-term illnesses.
- Patient safety is of the utmost importance when it comes to quality health care.
- The nursing scope of practice is the range of activities a nurse is permitted to perform, as defined by state's regulatory body.
- The QSEN project focuses on six main competencies: patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics.
- Each year, The Joint Commission gathers information related to emerging patient-safety issues. The organization then uses this information to create specific programs for its National Patient Safety Goals.
- PCC is essential to quality care, positive patient experiences, and optimal patient outcomes. Of all members of a care team, the nurse spends the most time with a patient, so they typically play the biggest role in PCC.
- PCC involves listening to each patient to understand their values, concerns, and directives. This practice should be the center of each individualized plan of care and treatment decision.
- The patient and their family should be treated as team members who participate in discussions and treatment decisions.
- Team members should provide information in a timely manner to ensure the patient and family are making well-informed decisions.

1.2 Intercollaborative Care

- Effective communication requires a wide range of skills. These skills include nonverbal modes of communication such as interpreting facial expressions and body language, listening attentively, and developing positive relationships with each team member, patient, and family member.
- ISBAR is an acronym that stands for Introduction, Safety, Background, Assessment, and Recommendation. The ISBAR format provides a structure of written communication that can be replicated by each team member to keep communication on track, create a workflow for the intercollaborative team, and promote patient safety.
- The intercollaborative health-care team comprises many individuals and entities. It works collaboratively through a team approach to promote whole-person care, which is patient-centered to promote optimal patient safety and outcomes.
- Critical thinking is a multidimensional, systematic, and organized way of thinking.
- Clinical judgement refers to the mental processes by which nurses draw on their knowledge and experiences to interpret the information in a particular case.
- Clinical decision-making refers to the process of drawing on experiences, research, and other sources of quality evidence to choose the best course of action for a particular patient in a particular context.

1.3 Health Policy and Ethical Considerations

- Health policy is defined by the World Health Organization as "the decisions, plans, and actions that are undertaken to achieve specific health-care goals within a society." It regulates the delivery of health care with the focus on optimal patient outcomes.
- Health policy is driven by nurses who are direct providers of patient care and, therefore, understand what patients value most, which is key to quality PCC.
- Being at the bedside, nurses develop a voice of expertise to advocate for health-care reform, including the delivery of care and patient safety.
- With the support of the ANA, nurses work diligently to make their voices heard at all levels where health policy decisions are made.
- SDOH are the nonmedical factors that have an influence on health outcomes. They include environmental factors such as where one was born, grew up, lived, and aged.
- SDOH also include a broader set of factors that shape daily life, such as access to health care and education, economic stability, community development, social and society norms, political systems, and race and

ethnicity.

- Ethics is the study of right and wrong actions. Ethical nursing emphasizes the principles of autonomy, justice, beneficence, and nonmaleficence.
- Autonomy acknowledges that patients have the right to maintain control and make their own decisions related to treatment and care.
- Justice is the principle of treating all patients fairly.
- Beneficence refers to the health-care provider's responsibility to act in their patient's best interests. The ANA defines beneficence as "actions guided by compassion."
- Nonmaleficence refers to the health-care provider's responsibility to do no harm.

1.4 Evidence-Based Practice

- Evidence-based practice (EBP) is the process of making clinical decisions based on the best available evidence from the most up-to-date research.
- EBP enables nurses to implement best practices in patient care.
- EBP promotes better outcomes, reduces costs, increases patient satisfaction, and maintains the relevance and currency of health care practices.
- Nurses involved in the delivery of care are instrumental in analyzing the current data (evidence) and refining the processes related to quality improvements.
- Nursing research provides the evidence that guides nurses in EBP.
- Research is conducted in five phases: conceptual, design and planning, empirical, analytic, and dissemination (Riva et al., 2012).
- Researchers often use the PICOT format to ensure their questions specify the population (or problem), the intervention, the comparison, the outcome, and the time frame.
- EBP and nursing research are similar, but they have different purposes. The purpose of research in nursing is to evaluate current knowledge and theories in order to formulate better nursing practices for improved patient outcomes, whereas the purpose of EBP in nursing is to use the evidence from research to make informed decisions regarding patient care and outcomes.
- QI focuses on improving the interrelated processes that affect patient outcomes and satisfaction.
- Nurses have a variety of ways to be involved in QI, including by analyzing nursing research and incorporating relevant findings into patient care guidelines.
- With EBP, assessing patient outcomes is the framework to develop standardized plans of care and clinical guidelines to promote QI.
- The quest for evidentiary knowledge that bridges the gap between theory and practice to improve patient outcomes continues to close with the advances and implementation of EBP.

1.5 Health-Care Delivery Systems

- The health-care delivery system is the organized manner in which health care is provided. It includes clinicians, facilities, insurers, and regulators.
- Inpatient services may be provided in hospitals, skilled nursing facilities, and rehabilitation centers.
- Outpatient services may be provided in outpatient surgery centers, acute care clinics, and a variety of specialty centers.
- Other services provide support for patients in their home settings, including some post-acute services and adult care services.
- Public health agencies use government funding to provide health care to a large, diverse population, including the poor and uninsured.
- Health-care systems provide different types of preventive services. Primary prevention aims to prevent disease before it occurs. Secondary prevention promotes early diagnosis and treatment to slow the progression of a disease or injury. Tertiary prevention aims to decrease the impact of an ongoing illness or injury.
- Advances in technology have changed the health-care delivery system. Telehealth is especially helpful for patients living in remote areas with limited access to health-care facilities.
- Factors that affect patient demographics include birth rates, the aging population, the number of people living in cities versus rural communities, the numbers of homeless people versus the number of families in an area,

socioeconomic status, and cultural diversity.
- SODH include income; job stability versus unemployment; education; access to insurance, routine health care, and quality care; and cultural diversity.

1.6 Systems-Based Practice

- SBP is health care that considers the multiple systems and interactions involved in a patient's condition and incorporates them into patient care.
- SBP requires team members to recognize microsystems (the relatively small systems in which each provider works) and the larger macrosystem in which all these systems coexist.
- SBP also requires team members to learn how to effectively use the systems in an interdependent manner, which is the cornerstone to providing optimal health care.
- Systems also include the rules and regulations that determine the relationships between components of the system and their responsibilities to patients and to each other.
- Nurses must recognize how different people function within each system as well as how each person's actions affect each aspect of the system.
- Nurses must have an awareness of the complexities of the system as well as a responsiveness and an ability to call on the other resources within the larger context and system of health care.
- Nurses should also be aware of the cost of care, clearly understand risks and benefits, possess advocacy skills for quality patient care, participate in interdisciplinary teamwork, and have the abilities to identify system errors and develop and implement system solutions.
- Interdisciplinary teamwork is essential to developing competence in SBP in today's health-care environment. It brings together team members with specialized skills and training from a variety of disciplines, thereby improving the delivery of care, patient outcomes, and health equity.
- Interdisciplinary teamwork encourages the coordination of solutions to identified problems.
- Interdisciplinary teamwork helps team members appreciate how others contribute to the care for each patient, leading to more holistic approaches and enhancing the delivery of PCC.
- Interdisciplinary teamwork promotes communication between each team member involved in the patient's care, enabling the team to have a better understanding of the patient's values and expectations.

1.7 Technology and Informatics

- Nursing informatics is defined by the ANA as "the specialty that integrates nursing science with multiple information and analytical sciences to identify, define, manage and communicate data, information, knowledge and wisdom in nursing practice."
- Nursing informatics focuses on the storage of data, information, and knowledge in computer programs and software in order to help health-care providers offer high-quality, safe patient care.
- Nursing informatics helps nurses make informed decisions and reduces medical errors, patient care delays, and health-care costs.
- Nurses use and communicate data, information, and knowledge in their daily practice.
- With the advancement of nursing informatics, patient information and interdisciplinary team notes are immediately available to each nurse for each patient to help with sound decision-making for patient care.
- In the nursing profession, technologies can help with daily routine processes and decrease the incidence of human mistakes and errors, especially for nurses working long hours with a heavy patient caseload.
- Technologies will never replace the human experience that is crucial for positive patient outcomes, but with the right balance, they can help ease the demands associated with direct patient care.
- HIPAA became federal law in 1996.
- HIPAA created national standards to protect a patient's privacy by preventing their health information from being disclosed without their consent or knowledge.
- HIPAA has two components: the HIPAA Privacy Rule and the HIPAA Security Rule.
- The Privacy Rule provides standards relating to the use and disclosure of an individual's health information, known as protected health information, by covered entities that are subject to this rule.
- The Privacy Rule also provides standards for individuals' rights to understand and control how their health information is used.
- The Security Rule protects public health information, which includes individually identifiable health

information that a covered entity creates, receives, maintains, or transmits in electronic form (known as electronic protected health information); it does not apply to PHI transmitted orally or in writing.

Key Terms

anonymity state of being unknown; refers to a participant in a study whose identity is not disclosed
autonomy right to make one's own decisions related to treatment and care
beneficence responsibility to act in the patient's best interest
clinical decision-making application of both critical thinking and clinical judgment to make decisions about nursing care
clinical judgment process by which nurses make decisions about patient care on the basis of observations, assessments, and interpretations of relevant information
collaborative care model approach to health care in which a team of providers works together to manage patient care more effectively and improve patient outcomes
critical thinking multidimensional, systematic, and organized way of reasoning
data pieces of information that help researchers answer questions and draw relevant conclusions
electronic health record (EHR) digital version of a patient's medical history; enables providers to immediately access information about a patient's health, including conditions, medications, and test results
empirical evidence objective data gathered by the senses from observations or experiments
ethics study of right and wrong actions
evidence-based practice process of making clinical decisions on the basis of the best available evidence from the most up-to-date research
full disclosure process of providing a complete description of a study or medical procedure, including the risks and possible benefits
health equity condition in which everyone has the same fair opportunities to attain the highest level of health outcomes
health inequities disparities created by socioeconomic systems and the status of different populations
Health Insurance Portability and Accountability Act (HIPAA) federal law to protect sensitive patient health information from being disclosed without the patient's consent or knowledge
health policy laws and regulations that define the actions and decisions that promote a society's health goals
health-care delivery system individuals and organizations collectively responsible for providing and overseeing health care in an area
informed consent legal document an individual signs to indicate a thorough understanding of a study, medical treatment, or procedure and to agree to participate
intercollaborative care team-based approach that uses shared responsibilities, interactive planning, and collaborative decision-making to promote person-centered care and improve patient and health system outcomes
ISBAR acronym that stands for Introduction, Safety, Background, Assessment, and Recommendation. The ISBAR format provides a structure of written communication that can be replicated by each team member to keep communication on track, create a workflow for the intercollaborative team, and promote patient safety
justice principle that all patients should be treated fairly
macrosystem culture or society that surrounds smaller systems and gives them structure
microsystem relatively simple, localized system, such as the one in which a health-care provider directly works
nonmaleficence responsibility to do no harm
Nurse Practice Act law passed by a state's legislature regulating nurses' scope of practice
nursing informatics specialty that uses information and technology to improve the efficiency of health care and its delivery
nursing research inquiry that is systematically designed to provide knowledge for important issues relevant to the nursing profession
patient-centered care (PCC) model of care that requires listening to patients to understand what they value most, then using the information as the catalyst for health-care decisions
PICOT acronym based on the elements of a clinical research question: population or problem, intervention, comparison, outcome, time frame
primary prevention health care intended to prevent disease before it occurs

qualitative research inquiry that focuses on personal experiences obtained through observation and interaction with patients
Quality and Safety Education for Nurses (QSEN) project focusing on the preparation of future nurses to promote the quality and safety of health-care systems
quality improvement (QI) framework to improve patient care and outcomes systematically
quantitative research inquiry that uses deduction and generalization from empirical evidence to draw conclusions
scope of practice range of activities a licensed person is permitted to perform as part of their work
secondary prevention health care that promotes early diagnosis and treatment to slow the progression of a disease or injury
social determinants of health (SDOH) nonmedical factors that have an influence on health outcomes
systems-based practice health care that considers the multiple systems involved in a patient's condition and uses evidence about their interactions to develop a treatment plan that incorporates all the entities involved in the patient's care
telehealth use of digital communications technology to remotely provide health-care services
tertiary prevention health care intended to decrease the impact of an ongoing illness or injury
The Joint Commission independent, not-for-profit organization that sets standards for quality care, quality improvement, and patient safety for organizations and workers in the health-care industry
theory–practice gap divide between theoretical knowledge acquired in academic settings and the practical application of that knowledge in real-world clinical settings
whole-person care holistic care that focuses on all of a patient's needs

Assessments

Review Questions

1. What action reflects The Joint Commission's contribution to a health-care organizations' improvement initiatives?
    a. setting standards for quality care, QI, and patient safety
    b. excluding nurses from safety and improvement initiatives
    c. focusing on emergency management and infection prevention
    d. eluding the National Patient Safety Goals

2. What component reflects a key element of PCC?
    a. excluding the patient's family from the care setting
    b. ignoring the patient's emotional well-being
    c. customize care based on the patient's values and perspectives
    d. respecting the patient's physical comfort

3. Ms. Hutto is complaining of pain (8 out of 10) in her lower back and abdomen. As the patient's nurse, you determine her abdomen is soft but distended, with positive bowel sounds in all four quadrants. Interventions such as ambulation, position changes, warm compresses, and warm prune juice have provided no relief. This scenario highlights what component of the ISBAR communication tool?
    a. situation
    b. background
    c. assessment
    d. recommendation or request

4. What is the primary goal of an intercollaborative care team in the context of patient-centered care?
    a. achieving financial targets
    b. streamlining administrative processes
    c. improving patient outcomes through personalized care
    d. minimizing the workload for health-care providers

5. A nurse is caring for a 72-year-old female with a diagnosis of atrial fibrillation. When making his shift change report, the nurse realizes that 4 hours ago, he administered 0.5 mg of the patient's antiarrhythmic medication

instead of 5.0 mg. When the nurse realizes the error and calls the physician to report the incident, what ethical principal is described in this situation?

a. nonmaleficence
b. justice
c. autonomy
d. beneficence

6. Mr. Johnson is scheduled for an endoscopy. Despite the excruciating abdominal pain he is experiencing, Mr. Johnson refuses to have the procedure. What ethical principal is described in this scenario?

a. beneficence
b. justice
c. autonomy
d. nonmaleficence

7. What option is a social determinant of health?

a. medical history
b. promotion of healthy choices
c. homelessness
d. life expectancy

8. As a nurse practicing EBP, what process related to improving patient satisfaction will be most effective?

a. checking on each patient's pain level every 4 hours
b. administering medications as close as possible to the administration times
c. making rounds on each patient hourly
d. offering a bath daily to each patient

9. Joann, a nurse in the medical-surgical unit, would like to implement a project to improve the cleanliness of patient rooms. Aside from the nurses, what group of key stakeholders should be included in the planning?

a. hospital maintenance staff
b. physical therapists and technicians
c. housekeeping staff and unlicensed assistive personnel
d. occupational therapy team

10. A nurse manager has received an increase in patient complaints that monitor alarms are sounding for extended periods, which is disrupting their sleep and creating unnecessary anxiety. After close observation, the nurse manager realized the nurses appeared as if they did not hear the alarms while charting. What type of QI plan would be most appropriate for the nurse manager to consider for her unit?

a. a plan of correction related to nurses not promptly addressing the monitor alarms
b. a process improvement project to address alarm fatigue
c. a plan to ensure all the patients have standing orders for medications to relieve their anxiety
d. a plan to have the nurses increase the volume of the monitor alarms

11. Ms. Blanchard is presently being treated for a new diagnosis of high blood pressure. Her primary care physician has recommended that, in addition to her daily dose of medication, Ms. Blanchard should also stop smoking. This recommendation demonstrates what level of prevention?

a. primary prevention
b. secondary prevention
c. tertiary prevention
d. intermediary prevention

12. What is an example of a statement that reflects the role an agency has on the health-care continuum?

a. Agencies provide a variety of in-home care, including physical and occupational therapy.
b. Government agencies exist to supplement middle-class populations.

c. All hospitals provide inpatient services at low to no cost to patients in need.
d. Subacute inpatient settings are no longer needed for sick patients.

13. What is the best description of systems-based practice in health care?
a. the focus on individual patient care, considering their immediate medical needs
b. the use of advanced medical technologies to enhance PCC and outcomes
c. recognizing the various layers of the health-care system and understanding how they impact patient care
d. implementing standardized procedures in health-care settings to ensure consistency in patient treatment

14. What is a nursing informaticist?
a. a nurse who is skilled at communicating complex information to patients
b. a nurse who is an expert on laws protecting patient information
c. a nurse who develops technologies that securely store and communicate information
d. a nurse who uses information and technology to improve the efficiency of health care

15. How has technology affected nursing education, particularly in sim labs?
a. by reducing the need for clinical experiences in real health-care settings
b. by providing high-tech sim labs with realistic manikins for hands-on practice
c. by eliminating the importance of critical thinking skills in nursing education
d. by decreasing the need for online platforms in nursing courses

Check Your Understanding Questions

1. What are the six main competencies of Quality and Safety Education for Nurses?

2. Identify examples of PCC in which the nurse takes an active role.

3. Identify two different social determinants of health and explain how they can affect a person's health.

4. What is the difference between EBP and nursing research?

5. Identify social determinants that affect the delivery of health care.

6. In your own words, define systems-based practice.

7. What building blocks of communication influence nursing?

8. What is the purpose of the Health Insurance Portability and Accountability Act?

Reflection Questions

1. Reflect on a recent patient you may have cared for during clinicals or discussed in a recent scenario in class. What questions could you have asked to guide you through the critical thinking process?

2. A 35-year-old patient with a history of opiate misuse is admitted to the emergency department with multiple stab wounds. Two days after extensive surgery to repair the wounds, the patient reports severe, unrelenting pain and reports the administered pain medication (an opioid) is not diminishing the pain. Because of the patient's history of substance use, some staff members do not believe the patient's reported pain level; they assume the patient just wants to obtain more medication. Keeping in mind the four main principles of nursing ethics, how do you address pain relief for this patient? How would you address the views of the staff members who believe the patient should not receive additional medication?

3. In your own words, describe what evidence-based practice is and why it is used in the nursing profession.

4. Why is SBP important in nursing?

5. Describe the impact of an interdisciplinary approach to health-care delivery.

6. How has medical technology improved the delivery of health care?

What Should the Nurse Do?

Mary, a nursing student in her final year of training, is about to start her clinical rotation at a busy urban hospital. She is eager to apply her knowledge and skills in patient care while adhering to the competencies outlined by the QSEN. During her first day on the medical-surgical unit, Mary encounters a patient named Mr. Johnson, a 65-year-old man admitted with a diagnosis of congestive heart failure.

1. What steps should Mary take to ensure she is adhering to the QSEN competencies in her care of Mr. Johnson?
2. How can Mary ensure that she effectively engages Mr. Johnson in his care to provide patient-centered care?
3. How can Mary empower Mr. Johnson to actively participate in his care decisions and express his treatment preferences to the health-care team?

Emily, a registered nurse working in a community health center, is caring for a diverse patient population. She encounters Mrs. Lopez, a patient with low income who is struggling to access affordable health-care services due to financial constraints. Emily recognizes the importance of advocating for Mrs. Lopez's needs and ensuring she receives patient-centered care despite socioeconomic challenges.

4. What SDOH might Emily consider when caring for Mrs. Lopez?
5. How can Emily fulfill her role as an advocate for Mrs. Lopez in providing patient-centered care?
6. How can Emily apply core principles of ethics when advocating for Mrs. Lopez's health-care needs?

Mark is a nurse working in a community health clinic that provides preventive health-care services to a diverse population. He encounters several patients with different health-care needs, ranging from preventive screenings and vaccinations to chronic disease management and health education. Mark navigates various factors influencing health-care delivery, including the role of health-care agencies and the availability of preventive services.

7. What actions should Mark take to differentiate between the types of preventive services available in the health-care system?
8. How can Mark discuss the impact agencies have on health-care systems based on his experiences in the community health clinic?
9. What factors affecting health-care delivery should Mark consider when providing care to patients in the community health clinic?

Competency-Based Assessments

1. During patient assessment, what cues might indicate that a patient's care is not adequately patient-centered, and how would you address these cues?
2. If a patient expresses dissatisfaction with their care, outline the steps you would take as a nurse to address their concerns and enhance the patient-centeredness of their care.
3. Explain how effective communication methods play a crucial role in the interdisciplinary health-care team. Provide examples of best practices for communication that enhance collaboration among team members.
4. Define critical thinking and clinical judgment in the context of health care. How do these cognitive processes impact the roles and interactions of members within an interdisciplinary health-care team?
5. As part of providing PCC, the nurse should determine a patient's cognitive abilities as well as any relevant knowledge deficits or learning disabilities. You are assigned to teach an older adult patient about medications they will be taking at home. Create a plan for assessing this patient's condition and psychosocial situation to determine how to best instruct her about her medications. Explain how you would modify your teaching plan if the patient were hard of hearing, visually impaired, or unable to read or write.
6. Identify three SDOH and explain how they can affect a patient's experience of care. Describe strategies a nurse can use to address these determinants and enhance PCC.
7. Describe a situation where ethical principles clash with health policy, creating a challenge for the nurse in advocating for PCC. How can the nurse navigate this dilemma to ensure ethical considerations guide patient care?
8. As a clinical nurse, how can you effectively incorporate both EBPs and nursing research into your daily practice to enhance patient care?

9. How can nurses actively engage in QI efforts to enhance the overall health-care experience for patients?

CHAPTER 2

Culturally Competent Care

FIGURE 2.1 Addressing culture is vital to effective health care. (credit: "Iraqi doctor" by Debbie Morello/USAID, Public Domain)

CHAPTER OUTLINE

INTRODUCTION Nursing student Jane is caring for a woman who emigrated from Sri Lanka. Jane does not speak the patient's language and is not sure how to proceed to address her unique needs, values, and beliefs about health and illness. She delivers good-quality care by administering medications properly and safely and by providing attentive nursing care but fears she may be missing important elements of her spiritual and cultural care. She wants to learn more about her culture to provide appropriate patient education to the patient and her family. Her experience with this patient has made her more interested in truly learning how culture can impact health and healing. By learning more about how culture can impact a person's health and wellness, nurses can provide effective care, improve health outcomes, and avoid stereotypes or biases that may hinder the quality of care.

2.1 Concepts in Culture

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the concepts of culture and race
- Describe cultural competence and cultural humility
- Discuss the importance of culture to nursing care

A fundamental principle of nursing is that every patient deserves to be respected and valued. This is especially important in a diverse society like ours, which contains individuals from a wide variety of cultural backgrounds.

Nurses who consider the impact of culture show respect for each patient's unique identity, beliefs, and needs. Patients who speak different languages or practice different customs or traditions may also have different ways of expressing themselves and interpreting other people's behavior. Learning to identify and accommodate these practices allows nurses to establish effective communication, which is essential for proper diagnosis and treatment. Sensitivity and open communication help nurses avoid biases that may impact the quality of their care. A **bias** is a tendency for or against a thing, person, or group, usually in an unfair manner. Furthermore, respecting the cultures and diversity of all patients is mandated by regulatory bodies and codes of ethics. Patients have the right to receive, and nurses are ethically bound to provide, culturally sensitive care (Office of Minority Health, n.d.). Culturally sensitive nursing care leads to improved health outcomes (Sharifi et al., 2019).

What Is Culture?

The characteristic beliefs, values, customs, traditions, behaviors, history, and artifacts shared by a particular group of people are considered their **culture**. It consists of a people's language, religion, social norms, art, cuisine, and many other components of society, and it plays a crucial role in shaping individual perspectives and behaviors, including health practices (Office of Minority Health, n.d.). Therefore, culture is a vital consideration in nursing care. Culturally relevant nursing care acknowledges and incorporates the cultural beliefs, values, and practices of patients into their health-care experience. Through this approach, nurses develop **cultural sensitivity**, which is the awareness of cultural differences and the potential impact they may have on an individual's beliefs, behaviors, and experiences. Culturally sensitive nurses recognize and respect their patients' diverse backgrounds and tailor care to meet each person's specific needs and preferences.

Differentiating Culture and Race

People sometimes confuse culture with terms such as *race* or *ethnicity*. For centuries, people held the belief that people could be divided into distinct racial groups, based on inherited physical characteristics, to justify racism, slavery, and all manner of discrimination. Today scientists reject this notion of race based solely on skin color. Instead, **race** is considered a social construct used to group people by certain physical, social, or geographic characteristics, such as skin color, language, or country of ancestry. For example, Black Americans practice a wide variety of religions, have different social traditions, and trace their ancestry to different parts of the world including Africa and the Caribbean.

Another social construct, **ethnicity** refers to shared key cultural traits, including traditions, heritage, and ancestry (Foronda et al., 2016). Nurses should not assume that people who share an ethnicity belong to the same culture. For example, the 2020 U.S. Census identified "Hispanic or Latino" as an ethnicity (Jensen et al., 2021), but this category includes people from any region with a Spanish or Spanish-influenced culture, including Spain, Mexico, Cuba, Puerto Rico, and many other parts of Central and South America and the Caribbean. All these subgroups have their own distinct cultural practices.

A culture based on ethnicity is often considered a primary element of culture, whereas secondary elements extend beyond the physical features and include other features (National Human Genome Research Institute, 2023). Members of a cultural group may share other characteristics, including age, sexual identification, social class, spiritual practices, and geographic location. Culture is also found in specific vocations or places of employment, for example, different companies may have different work cultures. Cultural groups can be found in the categories of marital or family status, political affiliations, levels of education, military service, hobbies, and any number of interests, beliefs, or practices. For example, married couples have a culture distinct from single people, and military members share a unique cultural bond distinctly different from that of the general public.

Generalizations and Stereotypes

A cultural group is made up of individuals who may be different in many ways but who nevertheless share several key traits. Concluding that every individual in a particular cultural group shares the same values, beliefs, or practices is a generalization. A statement may be true of a cultural group in general but not apply to every specific member of that group. For example, it is generally true that members of certain cultures avoid making eye contact with authority figures. A Chinese patient may consider it disrespectful to meet a provider's eyes, and a Muslim woman may consider it inappropriate to have a male provider (Galanti, 2000). However, nurses should not assume that every Chinese or female Muslim patient feels this way. To do so would be stereotyping.

A **stereotype** is a widely held but oversimplified assumption about a particular group of people. Stereotypes can

result from malice or bigotry, as when people hold racist or sexist views, and apply generalizations about a group to individual members of that group. Stereotypes often perpetuate fixed and biased ideas, portraying people in an unfavorable light without considering their individuality. Even when they do not put patients in physical danger, stereotypes can prevent nurses from building meaningful, trusting relationships with the individuals in their care each day. It is important to note that neither stereotypes nor generalizations can represent the full diversity and complexity of individuals within a cultural group. However, generalizations are typically grounded in observed, verifiable evidence, while stereotypes often rely on biases, assumptions, or misconceptions about a particular group.

Cultural Competence in Nursing

Multicultural awareness has become increasingly important for nurses as travel and communication have produced a "smaller," more interconnected world. Because we do not work in isolated communities where everyone is the same, we must be able to treat diverse populations effectively. This skill is part of **cultural competence**, which is the ability to effectively interact with individuals from different cultures. For example, nurses exhibit culturally competent care by delivering culturally tailored patient education and health promotion materials to help bridge the gap between health-care information and the patient's cultural beliefs and practices, enhancing their understanding, compliance, and self-management skills.

LINK TO LEARNING

Review this tool kit for cultural competence in nursing (https://openstax.org/r/77toolkit) provided by the American Association of Colleges of Nursing.

Evolution of Cultural Competence

The emergence of cultural competence as a concept in the nursing profession began with approaches such as the Sunrise Model, developed by Madeline Leininger in 1991, and Josepha Campinha-Bacote's Process of Cultural Competence in the Delivery of Healthcare Services, developed in 2002 (Leininger & McFarland, 2006; Campinha-Bacote, 2011). (See 2.2 Cultural Assessment for more information on these models.) As more nurses realized not only the necessity but also the value of delivering culturally relevant and sensitive care, the objective of cultural competence began to be incorporated into nursing curricula and professional standards (Marion et al., 2016). Some state boards of nursing have made cultural competence training a requirement for licensure, and nurse researchers are increasingly exploring evidence-based practices to guide culturally competent care (Gradellini et al., 2021; Long, 2012, 2016). Consequently, the utilization of resources like cultural assessments, cultural competence training programs, and cultural brokering services expanded. A **cultural broker** is a person who translates sociocultural differences between cultures. This could include nuances related to body language, expression, systems differences across cultures, or even how an experience may be viewed from a certain cultural lens. Cultural brokering goes beyond simple language interpretation.

REAL RN STORIES

Nurse: Sarah, RN
Years in Practice: Three
Clinical Setting: Cardiac step-down unit
Geographic Location: Suburban West Coast

Sarah, a registered nurse, was assigned to care for Mr. Patel, a 70-year-old immigrant from India who had recently undergone a cardiac procedure. Sarah understood the significance of providing culturally sensitive care to Mr. Patel and his family to promote a positive health-care experience. Upon meeting Mr. Patel, Sarah noticed his hesitancy and apprehension to be in the hospital. She decided to take a proactive approach by engaging in open and respectful communication. Knowing that Mr. Patel primarily spoke Gujarati, Sarah worked with the hospital's language services to arrange for a Gujarati interpreter to attend all interactions, either virtually or in person, when possible.

Sarah's efforts to bridge the language and cultural gap were instrumental in building trust with Mr. Patel and his family. She took the time to learn about their cultural values, religious beliefs, and health-care preferences. She discovered that Mr. Patel valued family involvement in decision-making and preferred natural remedies alongside conventional medicine. She used this knowledge to collaborate with the health-care team and adapt the care plan to align with these preferences. She involved his family in discussions, explaining medical procedures, medications, and potential side effects. As Mr. Patel progressed in his recovery, Sarah witnessed the positive impact of culturally sensitive care. The open lines of communication and shared decision-making resulted in increased patient satisfaction, improved adherence to the care plan, and a smooth transition to home care.

Cultural Humility

An attitude of openness, self-reflection, and lifelong learning regarding cultural differences is called **cultural humility** (Nguyen et al., 2020). Nurses with cultural humility recognize and challenge their own biases, practice respectful and nonjudgmental attitudes, and strive for equitable and patient-centered care. They also acknowledge the inherent power imbalances that exist in health-care settings. Nurses should be aware of the historical and systemic factors that contribute to health-care disparities among diverse populations, such as systemic racism and mistrust of health-care systems. By actively disrupting power imbalances, nurses can advocate for equitable care, promote social justice, and work toward reducing health-care disparities.

Elements of Cultural Humility

To effectively practice cultural humility, nurses must cultivate the essential elements listed in Table 2.1 (Nguyen et al., 2020).

Element	Description	Example
Self-awareness	Nurses must engage in continuous self-reflection to recognize their own cultural biases, assumptions, and limitations. By doing so, nurses become more open to learning about other cultures and challenging their preconceptions.	A nurse who has treated many Chinese American patients begins seeing an increasing number of recent immigrants from China. The nurse recognizes these new patients have different cultural backgrounds and therefore may not respond positively to approaches that have previously worked with Chinese American patients.
Openness to learning	Nurses practicing cultural humility approach encounters with individuals from diverse cultures as learning opportunities. They acknowledge gaps in their knowledge and actively seek reliable information about different cultures, including beliefs, traditions, values, and health-care practices.	The nurse admits they do not know enough about Chinese culture to provide culturally competent care to the recent immigrants. After discussing the issue with several Chinese American colleagues at the hospital, they are directed to several relevant books, podcasts, and websites.

TABLE 2.1 **Elements of Cultural Humility**

Element	Description	Example
Respectful communication	Effective communication is crucial for cultural humility, Nurses should strive to engage in active listening, using open-ended questions and empathetic responses to understand patients' cultural experiences and health-care needs. They should also be prepared to request translators to bridge language gaps.	The nurse does not speak Mandarin Chinese, the language spoken by her new patients. However, the hospital has contracted with a translation service, and the nurse is able to ensure an interpreter is always present for appointments, either virtually or in person.
Nonjudgmental attitude	Culturally humble nurses know enough about specific cultures to make reasonable generalizations about patients from those cultures. However, they refrain from stereotyping individuals based on their culture, and they do not negatively judge behavior that they do not sufficiently understand.	The nurse is accustomed to having warm, collaborative relationships with her Chinese American patients, particularly the younger ones who were born in the United States. The nurse is therefore surprised when younger patients from China remain distant, even guarded, after multiple appointments, but they assume the patients have understandable reasons for this behavior, and they remain positive during visits.
Collaborative partnership	Cultural humility promotes a collaborative partnership between nurses and patients. Nurses acknowledge patients as experts on their own culture, value patients' input, and actively involve them in making decisions regarding their care.	After several months, the nurse is pleased to find her efforts paying off. Her new patients are asking more questions about their health care, and while they still tend to defer to their providers' judgments, the nurse has used information from their conversations to help shape their treatment plans. With more time and positive reinforcement, the nurse believes the patients will become increasingly comfortable as active collaborators in their care.

TABLE 2.1 Elements of Cultural Humility

What Cultural Humility Achieves

Cultural humility is a vital part of the effort to promote patient-centered care and eliminate health-care disparities (Danso, 2018). In the context of nursing practice, cultural humility achieves several important outcomes relevant to these goals. First, it fosters respectful, nonjudgmental interactions with patients from diverse cultural backgrounds. Nurses practicing cultural humility recognize the inherent value of everyone's culture and avoid making assumptions or stereotypes based on cultural differences. This approach builds trust, strengthens nurse-patient relationships, and encourages open communication. The concept of **cultural safety**, which aims at creating an environment that is safe, respectful, and affirming for individuals of all cultures, particularly those from marginalized or oppressed backgrounds, also extends to the larger health-care system. Nurses bring cultural safety to the organizational and societal levels when they advocate for inclusive practices and policies that respect the rights and dignity of all individuals, and when they challenge discriminatory practices or barriers that may exist within their community. The following are examples of advocating for cultural safety:

- insisting that health-care providers use a language line or medical interpreter that speaks the patient's native language when providing information or obtaining consent
- collaborating with dietary services to offer a patient culturally appropriate food choices
- involving family members in decision-making

CLINICAL SAFETY AND PROCEDURES (QSEN)

QSEN Competency: Patient-Centered Care

Definition: Recognize the patient and family as a full partner in providing coordinated and compassionate care based on respect for the patient's preferences, values, and needs.

Knowledge: The nurse will integrate understanding of the multiple dimensions of patient-centered care and recognize how diverse backgrounds function as a source of patient and family values.

Skill: Provide patient-centered care while maintaining respect and sensitivity to their values. The nurse will do as follows:

- Complete a cultural assessment to determine the patient's values, preferences, and expressed needs.
- Document any patient requests in the medical record.
- Coordinate with ancillary staff in order to meet patient needs.
- Utilize resources as appropriate, such as a medical interpreter, to communicate with the patient and family.

Attitude: The nurse will respect and encourage patient expression of values and willingly support patient-centered care when a patient's values are different.

Impact on Health-Care Delivery

Culture influences an individual's beliefs, values, attitudes, and behaviors in all aspects of their life, including health and health care. It shapes their understanding of illness and wellness, as well as their perceptions of health-care providers and expectations of health-care services. By recognizing and acknowledging these cultural beliefs, health-care providers can engage in open and respectful discussions with clients and accommodate a patient's cultural preferences. Some cultures may prioritize natural or herbal treatments over pharmaceutical interventions or have specific dietary requirements (e.g., Jewish people may keep kosher, Muslim people may eat halal food, and Hindu people may not eat beef). Another example is a primary nurse who adjusts medication administration times to accommodate prayer times for a religious patient.

Cultural norms and values also affect patients' communication styles, expressions of pain or discomfort, and attitudes toward sharing personal information. Health-care providers need to be aware of these cultural nuances to ensure effective communication and care delivery.

2.2 Cultural Assessment

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe best practices for performing a cultural assessment
- Explain the models and theories that guide cultural assessment
- Explain the impact of a cultural assessment on patient outcomes

Completing a cultural assessment on a patient is important for nurses to provide holistic and patient-centered care. A **cultural assessment** is a method for systematically gathering information about a patient's cultural beliefs, values, practices, and perceptions as they relate to health care. A cultural assessment enables nurses to deliver care that respects individual cultural values, beliefs, and practices. By incorporating cultural consideration into nursing assessments, interventions, and care planning, nurses can improve health outcomes, enhance patient satisfaction, and contribute to the elimination of health-care disparities.

Performing a Cultural Assessment

A cultural assessment of a patient can take on many forms but should address some main factors that can easily be overlooked in a health-care setting. Assuming that all people are the same and view the world through the same lens is not a way to provide patient-centered care. Best practices for performing cultural assessments are informed by the work of numerous theorists. A model by Giger and Davidhizar is widely used.

Giger and Davidhizar's Transcultural Assessment Model

Giger and Davidhizar's Transcultural Assessment Model is a model used by the nursing and medical professions to providing culturally competent care to diverse patient populations (Giger & Davidhizar, 2002). Marilyn Giger and Ruth Davidhizar as nurse researchers and theorists contributed to transcultural nursing with the development of the Transcultural Assessment Model. The model is a standardized approach to assess cultural factors in nursing practice. The purpose of the model is to guide nurses in conducting a comprehensive and culturally sensitive assessment of patients by collecting data on the impact of cultural factors on health beliefs, health care–seeking behaviors, and treatment preferences (Giger & Davidhizar, 2002).

LINK TO LEARNING

Read this article on transcultural nursing (https://openstax.org/r/77transcultural) to learn more about Giger and Davidhizar's Transcultural Assessment Model and to see a visual of its application to nursing practice.

The Transcultural Assessment Model includes considering language barriers, nonverbal cues, and culturally appropriate communication styles, and understanding cultural perspectives on time, attitudes toward punctuality, scheduling, and the perception of illness (Giger & Davidhizar, 2002). The nurse must also recognize biological differences influenced by ethnicity, genetics, and race that may impact health outcomes. An example is the importance of recognizing that Black Americans are at higher risk of developing hypertension or sickle cell anemia. Cultural factors also influence the prevalence of high-risk behaviors such as substance misuse, unprotected sex, or unhealthy dietary practices. Nurses must assess and be aware of patient dietary restrictions, such as Orthodox Jewish people who request the kosher eating practice of not combining meat and dairy foods together and having food blessed by a rabbi. Pregnancy and childbearing practices are also impacted by culture as are rituals surrounding death, dying, and end-of-life care.

Cultural Considerations

When performing a cultural assessment, the views around several important concepts should be explored. These concepts are time, space, communication, social organization, environmental control, and biological variations. The following sections explore what is meant by each of these concepts and how they impact cross-cultural health-care experiences.

Communication

The concept of communication varies among different cultures due to a range of factors, including language, nonverbal cues, communication styles, and cultural norms. Communication is a complex process influenced by cultural values, beliefs, and practices, and even defined roles within the culture.

CULTURAL CONTEXT

Decision-Making across Cultures

Although it is assumed that people aged 18 years or older make their own decisions, that is not the norm in all cultures and family structures. For example, in the Hispanic patriarchy, the dominant male is in charge as the key decision-maker. In some African American cultures, the matriarch is considered a key decision-maker and must be counseled for family decisions. Social status within the Japanese culture may require the son of older parents to be the sole decision-maker, even if the eldest child or children are daughters. It is important to include the appropriate members of your patient's family to ensure everyone has the correct information and informed health-care decisions can be made.

Language plays a fundamental role in communication. All languages have distinct language patterns, such as dialects or slang, that can pose challenges in conveying and understanding messages accurately. Health-care professionals should be aware of language differences even within the same culture and utilize certified medical interpreters or translation services when necessary to ensure clear and accurate communication with patients. It is important to find out what language services are available at your health-care facility, including telephonic, live

interpreters, or even the use of live streaming for American Sign Language services.

Communication includes both verbal and nonverbal elements, with 90 percent of messaging coming mainly from nonverbal communication, which includes body language, facial expressions, gestures, and eye contact (Park & Park, 2018). In some cultures, eye contact may be seen as a sign of attentiveness and respect, such as in North American culture, while in others, it may be considered disrespectful or confrontational, as in American Indian or Asian cultures. Being sensitive and aware of these differences helps health-care professionals avoid misinterpretations and misunderstandings.

Communication styles can vary along a continuum, ranging from direct to indirect. In some cultures, direct communication is preferred, which is expressing thoughts and opinions explicitly, such as in North American or German cultures. However, in other cultures, such as American Indian or Asian cultures, indirect communication relies on nonverbal cues and context. Hierarchical structures represent the way individuals identify authority figures and social structure, and these also vary within cultures. Many cultures have a male hierarchy, which traditionally gives authority and preference to males making key decisions.

CLINICAL JUDGMENT MEASUREMENT MODEL

Analyze Cues: Determining Communication Style

Ms. Gonzalez has been admitted to the medical-surgical unit for a urinary tract infection. She seems very quiet and won't give the nurse a medical history. Twenty minutes later, her husband arrives on the unit and asks to speak to the nurse. When the nurse arrives, Mr. Gonzalez admits that his wife knows little English and that he can answer any questions the nurse has. The nurse decides to utilize a medical interpreter, who reveals that Ms. Gonzalez would prefer her husband to be in the room for all conversations.

The nurse compares the closed-off body language of Ms. Gonzalez before her husband arrived to the more open, relaxed body language she exhibits now that he's in the room. The nurse makes a note in the chart to have a medical interpreter and the patient's husband available for any care conversations or education.

Another element of cultural communication is high context versus low context, which considers the amount of implicit information shared. High-context communication requires an understanding of the background of the situation and person. For example, eye contact and physical touch can be interpreted in many ways without a context. In contrast, low-context communication, such as clear verbal communication and concise written communication, does not need additional context and conveys what someone is saying without having to read into a double meaning.

Cultural norms regarding politeness, formality, and respect can significantly impact communication. For example, some cultures prioritize maintaining harmonious relationships and may use indirect language to convey messages or avoid confrontation. In contrast, other cultures may value directness and explicitness. Being aware of these cultural variations helps health-care providers navigate sensitive topics and maintain effective communication. A nurse may be puzzled why a family is not making a critical health-care decision, but knowing there are layers of meaning and cultural implications may help the nurse develop more empathy.

Because communication is so complex, even when we speak the same language, remember that asking a patient an open-ended question to explain *what* they understand is better than asking the closed-ended question of *if* they understand.

Time

The interpretation of the concept of time varies among different cultures, and it significantly influences individual's behaviors, attitudes, and expectations. Some cultures may have a stricter monochronic approach to completing tasks on time, while others may complete multiple tasks at once and not pay a lot of attention to time. In health-care settings, understanding these cultural variations in the interpretation of time can help health-care providers communicate effectively, manage appointment scheduling, and address patient expectations. Being aware of these differences allows for more culturally sensitive and patient-centered care delivery.

Space

The concept of space is an important cultural concept for nurses to understand because it ,significantly influences patient care and interpersonal interactions. In the context of health care, space refers to the physical, psychological, and social dimensions that affect human relationships and communication. Respect for personal boundaries is important as different cultures have varying norms and expectations regarding personal space. Some cultures, such as the Latinx culture, may value closer physical proximity during interactions, while others may prefer more personal space, such as the Asian culture. Being aware of and respecting these differences fosters trust, enhances patient comfort, and promotes effective communication. Cultural norms regarding personal space and touch can differ significantly. An example is a female nurse who is unfamiliar with Japanese culture could inadvertently offend an older adult male when she goes to grab his arm to check his dialysis shunt without asking permission first. Another example is the offense a female Muslim patient may take if cared for by a male nurse who is trying to offer personal hygiene care.

Privacy is a fundamental right for patients, and nurses must honor this patient right. Honoring privacy respects patient's privacy and confidentiality. It involves providing adequate physical space for confidential discussions, ensuring appropriate privacy measures of closing doors or dividing curtains, and considering cultural norms when determining the level of privacy required for different individuals. As with any patient, nurses can design spaces that promote relaxation, reduce anxiety, and encourage a sense of peace.

Social Organization

The concept of social organization is highly relevant for nurses to understand because it plays a crucial role in shaping an individual's health beliefs, behaviors, and health-care experiences. Social organization refers to the way societies structure themselves, including their social hierarchies, roles, norms, values, and relationships. By comprehending the social structures and dynamics within a particular culture, nurses can better understand patients' health beliefs and decision-making and health care–seeking behaviors. For example, if a woman from South Asia is nonadherent in taking her medications, it may be due to a complex social structure within her family that the husband does not believe in Western medicine and she is to comply with his will.

Factors such as socioeconomic status, access to health care, discrimination, and power differentials within societies can greatly impact health outcomes. These are known as social determinants of health. For example, an immigrant family whose members do not have transportation or English fluency may struggle with tasks such as knowing how to get to a doctor's office or hospital. Different cultures have distinct family structures, kinship systems, and community networks that impact health-care decision-making, caregiving practices, and patient support systems. Trying to understand these dynamics can help a nurse serve as a patient advocate and connect the patient to resources. Striving to understand the social organization and its associated ethical perspectives allows nurses to navigate complex ethical dilemmas, respect cultural values, and ensure ethical care delivery.

Environmental Control

Some cultures may value the use of natural remedies or traditional healing practices that involve manipulation of the physical environment. By understanding these cultural perspectives, nurses can provide culturally appropriate care that respects and integrates patients' beliefs and practices related to environmental control. Cultural factors, such as dietary preferences, physical activity patterns, and exposure to environmental risks, are often influenced by environmental factors. Nurses who understand the cultural concept of environmental control can help patients identify and modify environmental factors that negatively impact their health and empower them to make healthier choices and lifestyle practices that are congruent with their cultural values.

Advocating for health equity can also help reduce health-care disparities caused by an unhealthy environment. An example would be supporting public policy that advocates for safe, lead-free housing for families who have a lower socioeconomic status. Another example is supporting community initiatives or providing education on environmental health hazards, such as air pollution or tainted water.

Environmental control is particularly relevant in the context of disaster preparedness and response. Different cultures have varying knowledge, beliefs, and practices regarding environmental emergencies. Some cultures may rely on governmental agencies to rescue and recover their belongings and food supply, whereas other cultures may be self-reliant. Nurses can enable individuals and families to develop culturally sensitive disaster plans, provide appropriate education and resources, and engage communities in disaster preparedness efforts. Through

recognizing the cultural dimensions of environmental control, nurses can provide culturally sensitive care, advocate for healthy environments, and empower individuals and communities to exert control over their physical surroundings resulting in improved health and well-being.

Biological Variations

The cultural concept of biological variations is essential for nurses to understand as it has a significant impact on health-care delivery and patient-centered care. Biological variations refer to the diversity and differences in human biology, genetics, and physiological processes that exist among individuals and populations. Genetic differences, metabolic variations, and susceptibility to certain diseases can vary across populations. Nurses can advocate for targeted screenings, genetic counseling, and interventions that address the specific needs of diverse populations. An example is a nurse who is aware that Ashkenazi Jewish people have an increased risk of having Gaucher disease, cystic fibrosis, and Tay-Sachs disease (National Gaucher Foundation, 2023).

Biological differences can influence how individuals understand and process health information. Nurses can tailor their communication to account for varying levels of health literacy, cultural beliefs, and individualized needs. When nurses acknowledge and validate the impact of biological factors on health outcomes, patients feel heard and understood. This fosters a therapeutic relationship built on trust, allowing nurses to deliver patient-centered care that acknowledges the unique biological needs and experiences of individuals.

Cultural Theory

While Giger and Davidhizar's theory and model are a good starting point for understanding the importance of performing a cultural assessment, there are other theorists and models that further explore the topic. In particular, Madeline Leininger, a pioneer in transcultural nursing, and Josepha Campinha-Bacote, who takes the theories of providing culturally competent care to a new level, ask health-care providers to engage in self-reflection and to retain a stance of "cultural humility."

Leininger's Cultural Care Diversity and Universality Theory

Leininger's Cultural Care Diversity and Universality Theory is a significant framework in nursing that emphasizes the importance of cultural factors in providing effective and culturally competent care. Developed by Madeleine Leininger, a nursing theorist and transcultural nursing pioneer from the University of Utah, this theory has had a profound impact on the understanding and practice of culturally congruent care. She stressed that the concept of culture was a central focus of nursing care. Her emphasis on the need for health-care professionals to develop cultural competence to provide effective care was key to really meeting the patient's needs. She introduced her Sunrise Model, which was an interplay between cultural and professional care factors in the delivery of culturally congruent nursing care. Understanding an individual's cultural history should include having knowledge of their heritage, migration, and historical experiences. Ideally, knowing about a patient would enhance the nurse's ability to deliver individualized care, yet the reality often challenges the time to obtain this information for every patient.

Leininger emphasized the need for a nurse to explore the influence of cultural values, beliefs, and practices on health-care decision-making and treatment choices. Individuals express and communicate their cultural values and beliefs through language, art, and even rituals. Her conclusion was that health-care professionals should address the potential need for modifying or reorganizing medical delivery or nursing practices to promote better health outcomes as needed for the patient's individual needs (McFarland & Wehbe-Alamah, 2019).

LINK TO LEARNING

The Transcultural Nursing Society (https://openstax.org/r/77tcns) was founded by Madeleine Leininger. It is a professional organization dedicated to promoting culturally congruent, equitable, and quality health care for all individuals. The society's website provides valuable resources, educational materials, and research articles related to cultural competence in nursing.

It also provides information on conferences, webinars, and educational events focused on cultural comptence development and offers access to publications such as the *Journal of Transcultural Nursing*, which features evidence-based practices and research findings on cultural competence.

Sunrise Model

Nurses can use Leininger's theory to conduct a cultural assessment to gather information about patients' beliefs, values, and practices following her Sunrise Model, which depicts elements of culture (McFarland & Wehbe-Alamah, 2019). The model depicts a bridge between nursing theory and practice. Strategies for implementing culturally congruent care interventions include using cultural brokers who understand the culture, interpreters who translate language, and appropriate communication techniques, such as culturally appropriate touch or lack of touch. The model focuses on shared human needs such as physical comfort yet incorporates the overarching concept of culture as individuals from different cultures may define health, illness, and pain differently. North Americans, for example, tend to be stoic with pain compared to Latine people who may be freer to express pain in verbal manifestations. Delivering culturally congruent care considers cultural nuances to promote understanding between nurses and patients from different cultural backgrounds. Providing culturally congruent care may improve patient satisfaction, and adherence to treatment can assist the nurse in recognizing unique needs, collaborating with the patient to find ways to accommodate their needs, and explaining the rationale for medical treatment in ways the patient can understand.

Campinha-Bacote's Process of Cultural Competemility in the Delivery of Health-Care Services

Josepha Campinha-Bacote created a new word, "competemility," which is a combination of the words "competence" and "humility" intended to guide health-care service providers through care that transcends cultural competence and addresses personal biases. The two-pronged approach of **competemility** asks one to *be* in the process of cultural humility and at the same time *become* culturally competent. Campinha-Bacote completed the final revision of the Process of Cultural Competemility in the Delivery of Health-Care Services in 2018. This model includes the mnemonic "A-S-K-E-D," which challenges those in health care to pose the following self-reflective questions:

Awareness: Am I aware of biases?
Skill: Can I conduct an assessment in a culturally sensitive way?
Knowledge: Do I have knowledge of different cultures and their respective health implications?
Encounters: Do I have encounters with diverse people? Do I want conflicts in such encounters to have positive outcomes?
Desire: Do I want to act with *competemility*?

Self-reflection on the A-S-K-E-D questions helps the health-care team members prepare for completing an assessment in a culturally sensitive manner.

Also, note the ambigram connecting "competence" and "humility."

The Impact of a Cultural Assessment

The impact of a cultural assessment can be profound if the nurse does not identify the unique needs of the patient. When conducting a usual physical and history patient assessment, the nurse should ask about any cultural or religious needs the patient may have. Conducting a cultural assessment for each patient is essential for the following reasons:

- provides individualized care
- improves communication
- fosters trust with the patient and family members
- identifies the patient's health beliefs and practices
- addresses health disparities
- complies with legal and ethical standards
- promotes interdisciplinary collaboration

2.3 Health Equity and Disparities

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define health equity and disparities
- Discuss the impact of social determinants of health on patient outcomes
- Explain how nurses can assess and customize care to decrease health disparities

Many factors can impact the way a certain patient receives care. From the fair or equitable distribution of health-care services to the differences with which one may access health care based on belongingness to a certain group, there are lots of reasons why a certain patient may have better or poorer health care. Social determinants of health play a large role in those variances; nurses should strive to provide quality care to all individuals regardless of these circumstances, and they should support equitable access and treatment for all.

Health Equity

The condition in which all individuals in a community have fair opportunities to achieve optimal health and receive appropriate, high-quality care regardless of their social or demographic characteristics is health equity (see Figure 5.2). Achieving health equity requires recognizing and addressing the root causes of health disparities. A **health disparity** is a difference in health outcomes and access to health care between different population groups (Agency for Healthcare Research and Quality, 2021). Essentially, health disparities are differences in health outcomes and access to health care between different population groups. These disparities are exacerbated by structural barriers such as systemic inequities and social injustices. Certain historically marginalized populations, such as communities of color and people living in underserved or impoverished areas, are disproportionately affected by health disparities and thus face higher rates of disease and health-care costs, lower quality of life, and early death (Collins, 2023). For example, consider the following in the United States (Collins, 2023):

- Non-Hispanic Black people have higher heart disease death rates than people of other racial and ethnic groups.
- Hispanic adults are the most likely to lack health insurance and have unmet needs for medical care.
- Adults with no high school diploma or GED are more than four times as likely to smoke cigarettes than someone with a bachelor's degree or higher.

Reducing health disparities and promoting health equity are crucial goals for health-care professionals. Nurses are well positioned to be leaders in these efforts, for example, by providing culturally competent care, advocating for at-risk populations, helping patients access all available resources, and collaborating with interdisciplinary teams and local organizations to bring health promotion and disease prevention programs to underserved communities. Through these and other measures, nurses around the world are working toward the day when every individual has a fair opportunity to live their best, healthiest life.

Social Determinants of Health

Health disparities are related to social determinants of health, or the conditions in which individuals are born, live, work, and age (Figure 2.2). These conditions, which play a critical role in shaping health outcomes, encompass a wide range of factors, including social environment, economic stability, and access to quality education, employment, housing, and health care (Healthy People 2030, n.d.). These social factors interact with biological and personal characteristics to influence an individual's health status and well-being. Recognizing and addressing social determinants of health is essential for nurses and health-care professionals to provide holistic, patient-centered care and promote health equity.

FIGURE 2.2 This graphic, created by the U.S. Department of Health and Human Services, organizes social determinants of health into five domains: economic stability, education access and quality, health-care access and quality, neighborhood and built environment, and social and community context. (credit: Office of Disease Prevention and Health Promotion, U.S. Department of Health and Human Services, public domain)

One of the key social determinants of health is **socioeconomic status (SES)**, which measures an individual's social and financial standing in their community, encompassing factors such as income, education, and perceptions of social class. Individuals with higher SES tend to have better access to health care, education, and employment opportunities; consequently, they have the resources to access and pay for quality health care (Healthy People 2030, n.d.). Lower SES is associated with limited access to health care, increased risk of chronic conditions, and higher rates of mortality. Nurses must understand the influence of SES on health outcomes and advocate for policies and interventions that address socioeconomic disparities, such as increasing access to affordable health care.

The physical and social environments where people live and work are also important social determinants of health. An individual's health is significantly affected by the quality of their housing, the safety of their neighborhood, and the robustness of their social support networks. Individuals living in a polluted neighborhood with limited access to healthful food and recreational spaces can contribute to stress, poor nutrition, and increased risk of chronic diseases. Nurses can play a role in promoting healthy environments by educating individuals and communities about environmental health risks, advocating for safe and accessible housing, and collaborating with community organizations to improve neighborhood conditions.

Two more social determinants of health to highlight are access to education and employment opportunities. Education is associated with better health literacy, healthier behaviors, and improved access to health care (Healthy People 2030, n.d.). Unemployment and job insecurity can lead to financial strain and increased stress levels as well as limited access to health care. Nurses can help to address these issues by providing education and resources to individuals and communities, advocating for equal educational opportunities, and assisting individuals in accessing employment and social support programs.

Nutrition and Nutritional Deficits

Nurses play a vital role in promoting culturally sensitive nutrition care. By understanding cultural influences on nutrition and dietary practices, nurses can educate individuals and communities about balanced diets that incorporate cultural preferences while meeting nutritional needs. Vegans, for example, do not eat any animal products, which can put them at risk for iron deficiency or folate deficiency anemia. Nurses can help vegans to collaborate with registered dietitians, cultural advisers, and community resources to develop appropriate nutrition plans. Moreover, nurses can advocate for policies that address food disparities, improve access to nutritious foods, and promote health equity. By considering cultural contexts, respecting dietary preferences, and addressing nutritional deficits, nurses can support individuals in achieving optimal health and well-being.

Holiday Observances

Holidays hold deep cultural and religious significance and often involve specific rituals, traditions, and dietary practices. Recognizing and respecting these practices is essential for providing culturally sensitive and patient-centered care. This includes understanding the historical and cultural context as well as the associated customs and practices. For instance, certain holidays may require modifications to the care plan to accommodate dietary restrictions, fasting practices, or specific rituals. Nurses should engage in open and respectful communication with patients and their families, seeking their input on how to incorporate holiday observances into care while maintaining safety and promoting well-being, especially during a hospitalization. Examples could include modifying a hospital menu for a Catholic patient who is fasting during Lent, and reorganizing a treatment schedule for a Muslim patient who wants to observe the five daily calls to prayer while hospitalized.

Educational Beliefs

Educational beliefs and values also differ across cultures and can have a significant impact on health care. In some cultures, for example, education is considered an essential component of health and well-being. Individuals from these cultures may place a strong emphasis on health literacy and view a provider as one of many possible sources of information.

Conversely, certain cultures take a more deferential approach to education and health care. Patients may rely heavily on health-care professionals for guidance and defer their decision-making authority to the health-care provider.

Cultural Groups and Disease Risk

Members of certain cultural and ethnic groups have elevated disease risks, which researchers have documented (Hill et al., 2023) (Table 2.2). Nurses should be aware of these risks to ensure they provide culturally sensitive care and targeted health interventions. At the same time, they must not stereotype. Table 2.2 shows common conditions seen among races at risk.

Ethnic/Cultural Group	Common Conditions
Black or African American	Hypertension, diabetes, obesity, breast, and prostate cancer (CentraState Healthcare System, 2022)
Hispanic/Latinx	Obesity, metabolic syndrome, diabetes, cardiovascular disease (Northwestern Medicine, 2024)
American Indian/ Alaska Natives	Type 1 diabetes, obesity, substance use disorder, alcoholism (Centers for Disease Control and Prevention, 2023)
Asian Americans	Chronic hepatitis B, tuberculosis (U.S. Department of Health and Human Services Office of Minority Health, 2023)
LGBTQIA+	Depression, sexually transmitted infections, suicide (Hafeez et al., 2017)

TABLE 2.2 Documented Risks for Disease Elevated in Certain Cultural and Ethnic Groups

How Nurses Can Customize Care to Decrease Health Disparities

To provide patient-centered care and decrease disparities, it is important to recognize any bias or stereotypical assumptions about patients from culturally diverse backgrounds. These biases can have negative effects on nurse-patient communication and interactions (Oruche & Zapolski, 2020). Nurses can help decrease health disparities on individual, organizational, and policy levels (Oruche & Zapolski, 2020).

On an individual level, nurses can decrease health disparities by providing culturally competent care. Strategies that nurses can use to incorporate culture in their plan of care are as follows:

- Ask the patient about their cultural traditions and preferences. By doing this, the nurse can gain insight into the client's values and beliefs and incorporate these elements into the plan of care in a way that is respectful and meaningful to the patient.
- Use interpreters. If the patient and the nurse do not speak the same language, using an interpreter can help the nurse understand the patient's beliefs and preferences. This can help the nurse incorporate these elements into the plan of care.
- Involve family members (when culturally appropriate). Family members can play an essential role in incorporating traditions and personal views into the care plan. Involving family members in discussions about the plan of care can help the nurse understand the patient's cultural beliefs and preferences.
- Be flexible. Being willing to adapt the plan of care to meet the patient's needs and preferences is essential. This can involve adjusting the timing of treatments or medications to accommodate the patient's religious practices or dietary restrictions.
- Use culturally appropriate resources. Educational materials and videos can help the nurse provide respectful and culturally sensitive care.

INTERDISCIPLINARY PLAN OF CARE

Plan of Care for an Underserved Patient

For a patient with little to no resources or low SES, a comprehensive interdisciplinary plan of care would be crucial to address patient needs after discharge. The nurse and provider begin by recognizing any needs that the patient may have during a comprehensive admission assessment. After the identification of needs, they would collaborate with the social worker.

Social workers would assess the patient's social support network, financial resources, and housing stability. They would assist in navigating insurance coverage for medications, accessing community resources for support groups, and addressing any legal or employment concerns.

Pharmacists would collaborate with the provider and patient to ensure proper medication adherence, educate the patient on potential side effects, and monitor for drug interactions. They would also assist in managing medication schedules and addressing any concerns the patient may have about their treatment regimen. If necessary, pharmacists would also counsel the provider about medications, such as generics or combination pills, that could be substituted into the regimen to increase patient compliance.

This interdisciplinary approach ensures that the patient receives comprehensive care addressing social and pharmaceutical aspects of their health. It emphasizes the collaborative effort needed to manage care effectively and improve the patient's quality of life.

On an organizational level, nurses can assist with creating an inclusive workplace culture, developing policies that foster inclusion and diversity, and providing adequate training and education resources. Supporting weekend clinic

hours can increase community access to care. Assisting with improving health-care access through telehealth services and mobile health clinics can also decrease community health disparities (Oruche & Zapolski, 2020).

On a legislative or policy level, nurses have the health-care knowledge to inform policymakers about the health-care needs of disadvantaged populations and advocate for policies that nurture increased patient access (Oruche & Zapolski, 2020). Nurses can push for better accessibility of cultural services, such as interpreter services.

Summary

2.1 Concepts in Culture

- Culture consists of the characteristic beliefs, values, customs, behaviors, and artifacts shared by a particular group of people. Conversely, race is used to group people by certain physical or geographical characteristics, and it is a social construct.
- Culturally sensitive nurses recognize and respect their patients' diverse backgrounds and tailor care to meet each person's specific needs and preferences. Although they recognize that generalizations about cultural groups may be valid and used to guide practice, they avoid stereotypes (widely held but oversimplified assumptions about groups).
- Cultural competence is the ability of health-care professionals to provide effective care to patients from diverse cultural backgrounds. It has become a focus in nursing practice, reflecting the growing recognition of the influence of culture on health care. Embracing cultural competence as an ongoing journey is crucial for nurses to provide patient-centered care in an increasingly multicultural society.
- Cultural humility takes cultural competence a step further. It is an attitude of openness, self-reflection, and lifelong learning regarding cultural differences. Cultural humility enhances equitable care, promotes social justice, and works toward reducing health-care disparities by asking nurses to recognize and challenge their own biases, practice respectful and nonjudgmental attitudes, and strive for equitable and patient-centered care.
- There are many reasons for nurses to deliver culturally sensitive care, including improved communication and increased trust between patients and caregivers, improved outcomes for patients, and a reduction of health disparities in society.

2.2 Cultural Assessment

- Completing a cultural assessment helps the nurse identify unique needs the patient may have.
- Giger and Davidhizar's Transcultural Assessment Model provides a best practice on how to conduct a comprehensive and culturally sensitive assessment by collecting data on the impact of cultural factors on health beliefs, health care–seeking behaviors, and treatment preferences.
- Factors such as language barriers, nonverbal cues, culturally appropriate communication styles, understanding cultural perspectives on time, and the perception of illness are important to include in a cultural assessment and care.
- Cultural assessment can illuminate differences in concepts of time, space, communication, social organization, environmental control, and biological variations.
- Leininger's Cultural Care Diversity and Universality Theory emphasizes the importance of cultural factors in providing effective and culturally competent care. Her Sunrise Model helps nurses recognize culturally specific needs and the necessity for collaboration between the nurse and patient to accommodate those needs. This is culturally congruent care.
- Josepha Campinha-Bacote's Process of Cultural Competemility in the Delivery of Healthcare Services combines the ideas of "competence" and "humility" to create the concept of competemility. This encourages health-care providers to self-reflect on questions aimed at providing care that transcends cultural competence and addresses personal biases.
- A cultural assessment identifies the patient's health beliefs and practices to help the nurse provide individualized care, improve communication, and foster trust. In addition, a cultural assessment complies with legal and ethical standards, promotes interdisciplinary collaboration, and addresses health disparities.

2.3 Health Equity and Disparities

- Health equity is the condition in which all people have a fair opportunity to achieve optimal health and receive appropriate, high-quality care regardless of their social or demographic characteristics. Health disparities are differences in health outcomes and access to health care between different population groups.
- Social determinants of health are the conditions in which individuals are born, live, work, and age. They impact access to and the ability to afford health care, safety and security, nutritional status, lifestyle choices, stress levels, and health literacy, to name a few.
- Factors that impact health include nutrition, holidays observances, educational beliefs, and risk factors for

illness.

- Nurses can help decrease health-care disparities through culturally competent patient care, supporting their organization with increasing health-care access, and supporting legislation that addresses health-care disparities in the community.

Key Terms

bias tendency for or against a thing, person, or group, usually in an unfair manner
competemility word created to combine "competence" and "humility" for cross-cultural delivery of care
cultural assessment method for systematically gathering information about a patient's cultural beliefs, values, practices, and perceptions as they relate to health care
cultural broker person who translates sociocultural differences between cultures
cultural competence ability of health-care professionals to provide effective care to patients from diverse cultural backgrounds
cultural humility attitude of openness, self-reflection, and lifelong learning regarding cultural differences
cultural safety aim of creating an environment that is safe, respectful, and affirming for individuals of all cultures, particularly those from marginalized or oppressed backgrounds
cultural sensitivity awareness and recognition of cultural differences and the potential impact they may have on an individual's beliefs, behaviors, and experiences
culture characteristic beliefs, values, customs, traditions, behaviors, and artifacts shared by a particular group of people
ethnicity social group that shares key cultural traits, including traditions, heritage, and ancestry
health disparity difference in health outcome and access to health care between different population groups
race social construct used to group people by certain physical, social, or geographic characteristics
socioeconomic status (SES) measure of an individual's social and financial standing in their community, encompassing factors such as income, education, and perceptions of social class
stereotype widely held but oversimplified assumption about a particular group of people

Assessments

Review Questions

1. What statement best reflects the importance of cultural awareness in nursing practice?
   a. Cultural awareness is necessary to avoid legal liabilities.
   b. Cultural awareness helps nurses identify patient's insurance coverage.
   c. Cultural awareness enhances nurses' understanding of patients' unique needs.
   d. Cultural awareness is required for nurses' continuing education.

2. What is an action that demonstrates cultural competence in nursing care?
   a. assuming all patients from a particular culture have the same health-care preferences
   b. using interpreters to facilitate effective communication with patients who speak a different language
   c. ignoring patients' cultural practices and focusing solely on evidence-based interventions
   d. applying stereotypes to guide the delivery of care to patients from different cultural backgrounds

3. How can nurses avoid stereotypes when delivering culturally competent care?
   a. Engage in self-reflection and recognize personal biases and assumptions.
   b. Assume that patients from the same culture share similar health beliefs and practices.
   c. Provide standardized care regardless of patients' cultural backgrounds.
   d. Avoid communication with patients who do not speak the same language.

4. What is a description of cultural awareness in nursing?
   a. understanding the importance of personal space in patient interactions
   b. having knowledge of various cultural practices and beliefs
   c. recognizing and respecting cultural differences in health care
   d. being aware of the influence of social determinants of health

5. A nurse is conducting a cultural assessment for a patient. What step should the nurse take to complete the cultural assessment effectively?
    a. Ask the patient about their personal medical history.
    b. Gather information about the patient's cultural background.
    c. Focus solely on the patient's physical symptoms.
    d. Skip the assessment if the patient appears uncomfortable discussing cultural beliefs.

6. A nurse is caring for a patient from a different cultural background. What is an example of an action by the nurse that demonstrates cultural competence?
    a. providing care based solely on the nurse's own cultural beliefs and practices
    b. utilizing a standardized care plan for each patient
    c. engaging in self-reflection and seeking knowledge about the patient's cultural background
    d. avoiding discussions about cultural beliefs and practices to prevent misunderstandings

7. What are components of culture? Select all that apply.
    a. interpretation of time
    b. comfort for personal space
    c. food preferences of dairy versus meat
    d. social position
    e. roles in the family

8. What is a description of the impact of culture on health?
    a. Culture has no significant impact on health outcomes.
    b. Culture only affects dietary habits and has minimal impact on overall health.
    c. Culture affects physical health but has no influence on mental health.
    d. Culture plays a crucial role in shaping health beliefs, behaviors, and practices.

9. What is a description of social determinants of health?
    a. genetic factors that influence an individual's health status
    b. biological conditions that contribute to disease development
    c. social, economic, and environmental factors that impact health outcomes
    d. individual's personal lifestyle choices and behaviors

10. What is a statement that accurately describes health disparities? Select all that apply.
    a. Health disparities refer to differences in health outcomes and access to health care between various populations.
    b. They can be attributed solely to genetic factors.
    c. Socioeconomic status, race, and ethnicity are factors that contribute to health disparities.
    d. Health disparities are limited to physical health conditions.
    e. Health disparities can be eliminated by providing equal access to health-care services.

Check Your Understanding Questions

1. How are cultural sensitivity, cultural competence, and cultural humility different?
2. How does a cultural assessment have a positive effect on patient outcomes?
3. What are some ways you can decrease health-care disparities?

Reflection Questions

1. How can you assess and address your own prejudices and biases when providing care to patients?
2. As a nursing student, reflect on your own cultural awareness by answering the following question:

    How has your cultural background and experiences shaped your perspective on health care and patient care

delivery? How do you feel about people who are ill, Black, White, Asian, Hispanic, LGBTQIA+, single, divorced, widowed, disabled, or who have obesity or substance use disorder?

3. You are a nursing student completing a clinical rotation in a community health center with a diverse patient population. As part of your learning experience, you are assigned to assess the health risks and needs of individuals from various cultural backgrounds. What factors will you consider to best customize your care of the following groups: Black American and LGBTQIA+.

Reflect on the following scenario and consider how nurses can effectively assess for health risks in different cultures You are assigned to work with a group of recent immigrants from Southeast Asia who have settled in your community. Many of them have limited English proficiency and adhere to traditional cultural practices that you are not familiar with. As you interact with the individuals, you notice some common health concerns, such as high rates of hypertension and diabetes within the community. Answer the following questions regarding this cultural group:

4. What cultural factors should you consider when assessing the health risks of individuals from Southeast Asia?
5. What culturally sensitive assessment techniques can you utilize to gather relevant health information from individuals who may have different cultural beliefs and practices related to health and wellness?
6. How might your own cultural biases and assumptions influence your assessment, and how can you remain culturally humble and open-minded in your interactions?

What Should the Nurse Do?

1. Ms. Rodriguez, a 40-year-old Hispanic female, is admitted to the hospital with a newly diagnosed chronic illness of type 2 diabetes. She speaks conversational English and primarily communicates with her family members in Spanish. The nursing team is responsible for providing her with culturally sensitive care and ensuring effective communication. When the nurse explains how to take her metformin and test her blood glucose daily, Ms. Rodriguez replies, “Si, dios quiere,” which interpreted means, “If God wants it to be.” How would you reply to Ms. Rodriguez’s response?

2. You are a nursing student assigned to care for a patient from a cultural background different from your own. The patient’s cultural beliefs and practices are unfamiliar to you, and you want to ensure that you provide culturally sensitive care. What should you do to promote cultural awareness in this situation?

You are a nurse working in a community health clinic. One of your patients, Ms. Johnson, a 45-year-old single mother of two children, recently lost her job due to company downsizing and is struggling to make ends meet. She has been experiencing chronic stress and anxiety due to her financial situation and has begun smoking again. She also lives in a neighborhood with limited access to fresh and affordable nutritious food options and buys fast food for her children almost every day. Her children attend a school where there is a lack of physical activity programs and limited access to health-care services. They have also been struggling academically due to the stressors at home. As her primary care public health nurse, you recognize the significance of addressing the social determinants of health in improving Ms. Johnson’s overall well-being.

3. What social determinants of health are impacting Ms. Johnson’s health status and well-being? Identify at least three social determinants in her case.
4. How can you collaborate with other health-care professionals, community organizations, and social workers to address the social determinants of health affecting Ms. Johnson and her children?

Competency-Based Assessments

1. Give an example of what you could say to apply each of the essential elements of cultural humility (self-awareness, openness to learning, respectful communication, nonjudgmental attitude, and collaborative partnership) now as a nursing student providing care for patients (actual or simulated).

2. Develop a ten-minute presentation to train the nurses on your unit to identify techniques used for a cultural assessment.

CHAPTER 3

Health Promotion and Patient Education

FIGURE 3.1 Nurses have an obligation to promote health to all members of their patient population. Patient education and health-promotion activities are important to improve the health for all members of society. (credit: Sgt. Ashley Tsoi/U.S. Air Force/TRICARE Newsroom, Public Domain)

CHAPTER OUTLINE

INTRODUCTION Health promotion and patient education may be the most important interventions that nurses perform for patient care. Promoting optimal health one patient at a time can effectively and efficiently decrease the rates of health-care problems and improve the quality of life for individuals, which leads to improvement of large groups or the population as a whole. Patient education affects health-care outcomes because it gives the patient the information they need to understand why and how to achieve their health and wellness goals. Nurses must elevate the importance of health promotion and patient education in their clinical practice at all stages of life.

3.1 Health Promotion and Wellness

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define key components of health promotion
- Identify factors that nurses must consider when developing a health-promotion plan of care
- Discuss the role of key components of health promotion and how to maintain a holistic, patient-centered approach to health promotion

Health promotion and preventive health measures are foundational nursing interventions, and they are becoming more and more important as the climate of the health-care industry shifts from a reactive to a proactive (preventive) model. Nurses need to understand why people value being healthy, what motivates them to make choices related to their health, what can convince them to make lifestyle changes for better health outcomes, and, of course, what health means. Nurses also need to understand that the concept of health has changed over time and varies according to culture and across the lifespan. Health was previously considered to be the absence of disease or similar problems. But current conceptions establish that **health** is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity (World Health Organization, 1946).

People may receive health information, but it does not always result in changes in lifestyle or health-related behaviors. The Health Belief Model (Rosenstock, 1974) suggests that even though people recognize the consequences of poor health behaviors, they will not take action to change their behaviors unless:

- they believe that they are susceptible to (at risk for) the health condition;
- the health condition poses serious consequences;
- behavior change will result in decreased risk;
- the benefits of change will outweigh the costs of change;
- they believe they can change their behaviors and the changes will pay off (Paul, 2020).

For nurses to positively affect people's health through health promotion, according to the Health Belief Model, the information presented to patients must be individualized, relevant to their current lifestyle, and provide enough facts for the patients to make behavior changes. Consider the use of pamphlets; if a nurse determines that a patient is at risk for a sexually transmitted infection (STI), the nurse would typically provide the patient with a pamphlet to read regarding prevention of STIs. Evidence reveals, however, that providing pamphlets without additional educational interventions is ineffective (Bhattad & Pacifico, 2022). A written pamphlet may not include all the information needed for the patient to believe they can make the needed lifestyle change. The nurse should explain why the patient is susceptible to an STI, explain the consequences of contracting an STI, and provide the patient with education on safe sex practices.

Betty Neuman (2011), a nursing theorist, describes a person's health as a continuum in which illness and wellness are opposite states of being. According to Neuman, the response to stressors (health issues) can move people across the continuum toward illness or wellness. A nurse's responsibility when a person experiences a stressor is to intervene with the appropriate level of prevention, either primary, secondary, or tertiary. The prevention of health issues through identification of risk factors and education and intervention to reduce the amount of risk for those health issues before they ever occur is primary prevention. Examples include wearing a helmet while biking or getting immunizations. In secondary prevention, a provider decreases the impact of a health issue through early detection, intervention to slow the progression of an illness, or rehabilitating to a former health state. Examples include a Pap smear for detection of cervical cancer or a mammogram for detection of breast cancer. When a patient has a chronic health problem, tertiary prevention is intervention to prevent further complications, improve functional ability and quality of life, or extend life expectancy.

To focus nurses and other health-care providers on the most important health-care issues, the U.S. Department of Health and Human Services (2023) created the guide Healthy People 2030. The Healthy People 2030 guide supports the development of health promotion and wellness goals for U.S. residents. Healthy People 2030's goal is for each member of society to have the ability to attain optimal health and well-being during each stage of their life (U.S. Department of Health and Human Services, 2023).

LINK TO LEARNING

Review the information on the priority areas of focus: [health equity, social determinants of health, and health literacy (https://openstax.org/r/77PriorityAreas)](https://openstax.org/r/77PriorityAreas) from Healthy People 2030.

Health Promotion

The holistic and proactive process of prevention of health issues through which people are empowered to take

control of their health-related choices and reach the best possible health status is called **health promotion**. In health promotion, nurses act as coaches and guides to promote healthy choices rather than authorities that offer prescriptive guidelines and treatment for established health issues only. Health promotion is a holistic practice, which is a departure from the traditional medical model. While the health-care provider plans and prescribes treatment based solely on the medical diagnosis, holistic health promotion empowers patients to meet their own health needs through knowledge and action in their personal, social, or environmental situations. For example, a person who has an addiction can be treated with medication to help decrease their cravings for a substance, but if that person is not empowered to change their social and environmental habits, they will find themselves in the same friend group or social group and will have barriers to maintaining their sobriety. If the patient with an addiction is given medication-assisted treatment, provided with social supports that encourage new relationship building, and empowered to feel strong enough to make needed behavioral changes, they are more likely to be successful in recovery.

If health is defined as optimal functioning and the absence of physical, mental, or social problems, then health promotion must include:

- disease prevention and management
- patient participation in their health-care plans
- healthy lifestyle education
- patient understanding of treatment options
- partnership
- open communication
- social justice
- mental health support

The seven core principles of health promotion are summarized in Table 3.1.

Principle	Description
Empowerment	Facilitating the patient's independence and proactivity
Participation	Engaging the patient in their health-care decisions
Holism	Treating the patient as a whole being, addressing mind, body, and spirit
Intersectionality	Realizing that there is overlap in social categories (race, ethnicity, etc.)
Equity	Providing equal health care to every individual regardless of background
Sustainability	Maintaining change over a long period of time
Combining multiple strategies	Using more than one of the principles of health promotion at once

TABLE 3.1 Core Principles of Health Promotion (Rootman, 2001)

Positive Health Concept for Ideal Health Promotion

A **positive health concept** is a subjective view of one's health status that allows a person to function at optimal levels, cope with life's stressors, and maintain a feeling of satisfaction, even though they experience stressors (Vermunt et al., 2018). Research by Dr. Martin Seligman (2024) found that people with a higher level of life satisfaction can cope with health issues better than those who have lower life satisfaction. An optimistic or positive health concept increases the acceptance of health promotion and teaching because the person believes that they are capable of behavior changes that will positively impact their health status. A patient's outlook on their health can change the course of their well-being: Positive outlooks are linked to positive health outcomes, whereas negative outlooks are linked to more health challenges.

Participation and Involvement for Ideal Health Promotion

The concept of health is shifting from being defined as the absence of disease to a positive health model with the overall goal of positive health and wellness (Doornenbal et al., 2022). Ideal health promotion is a concept in which nurses partner with patients to help them achieve their personal health and wellness goals (Figure 3.2) (Fertner & Grim, 2022). Partnership between the patient and nurse is essential in creating individualized health and wellness optimization according to the patient's values. Allowing room for this individualization based on the patient's personal value set takes into consideration their cultural background, therefore improving cultural sensitivity in the delivery of health care.

FIGURE 3.2 A health-care provider–patient partnership is the ultimate goal of patient health-care involvement. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Creating a patient partnership and involving the patient in their health-care choices is using a person-centered approach. When employing a person-centered approach, the nurse focuses on the person and their experiences instead of solely focusing on the disease process and its symptoms. A person-centered approach to health care builds on the nurse-patient partnership and allows patients to have information about and collaborate in the planning, delivery, and evaluation of their care while ensuring the patient's dignity (Fertman & Grim, 2022).

Action Competence for Ideal Health Promotion

The **action competence learning model** is a critical thinking model that is used to create health-promotion activities (Figure 3.3). Action competence informs the health-promotion delivery process for nurses to plan, act, and evaluate actions with the aim of improving health outcomes for a patient population. The action competence learning model can be used with patients, nursing students, or nurses to guide them through the process of transferring knowledge and self-awareness, being accountable for the actions taken, and reflecting on the results of the action (Bergen & Santo, 2018).

FIGURE 3.3 Health-promotion activities are developed using the action competence learning model. (credit: Untitled by New Zealand Curriculum; CC BY 3.0)

When action competence is applied to a group, community, or population, it is considered **collective action competence**. Collective action competence can be applied to health promotion as the capability of a population to direct their health and wellness behaviors toward common health and wellness goals based on collective health-care literacy, collective health competence, and collective health needs or goals. One example from the Healthy People 2030 is to increase medical care to rural areas noted as underserved.

Equity and Health for Ideal Health Promotion

Health promotion, well-being, positive health, and optimal health should be facilitated through a health-care system that treats people from all backgrounds equally. Patients from all backgrounds should have the same opportunity to achieve their health-care goals through health promotion and the guidance of their health-care team. This equal opportunity to achieve desired health-care outcomes is called **health-care equity**. Nonetheless, health-care disparity is plaguing the U.S. health-care system and blocking certain groups from equal access to health care. When a certain group of people have worse health outcomes than other groups of people for no obvious medical reason, it is called **health-care disparity**. For example, recent data in the United States concludes Black maternal mortality (death) is 55.3 per 100,000 live births, whereas White maternal mortality is 19.1 per 100,000 live births (Hoyert,

2023).

Health promotion is not a privilege; it is a right that should be provided to every human. It is important to consider health-care equity when planning health-promotion activities for patient populations. The social determinants of health are factors that appear to fall outside of the health-care system but play an active role in the health outcomes of a population. Therefore, health-promotional activities should take social determinants of health into consideration and target a diverse audience while striving to improve the health outcomes for all. Social determinants of health take into consideration many aspects of a person's life, such as birth, childhood, education, work, play, worship, and aging, which impact health, functioning, and quality-of-life outcomes. The World Health Organization (WHO, 2024) identifies the following items as social determinants of health:

- access to health services
- culture
- education levels
- employment and working conditions
- genetics
- gender
- income and social status
- personal behavior and coping skills
- physical environments
- social support networks

LINK TO LEARNING

Social determinants of health are not always easy to identify in a patient population. Using a screening tool can improve the identification rate of social determinants of health and increase the health promotion of people who are the most in need. A screening tool from the Centers for Medicare and Medicaid Service (https://openstax.org/r/77ScreeningTool) can be used with any patient population.

Wellness

Wellness and *health* are often used in context to mean the same thing; however, **wellness** is the subjective interpretation of a person's state of holistic health (Pender et al., 2018). When a person experiences wellness, they feel satisfaction with their physical, mental, spiritual, and social health status. Nurse coaching is a nursing specialty that focuses on assisting people to improve their overall wellness, gain a sense of well-being, and achieve life balance (Dossey & Keegan, 2020). The nurse coach partners with patients and provides a safe space for exploration of the patient's wellness goals. The goal of the nurse coach/patient partnership is to engage the patient in the process of identifying, assessing, planning, and evaluating behaviors that could be changed to improve health or to reach wellness goals.

Physical Wellness

While exercise is extremely important for people to achieve optimal levels of health and wellness, it is not the only aspect of physical wellness that exists. A person's **physical wellness** is their optimal physical function, which includes maintaining healthy nutrition, proactively seeking treatment for medical issues, and minimizing risky health behaviors (Melnyk & Neale, 2018). Table 3.2 lists the factors involved in maintaining physical wellness.

Factor	Examples
Healthy dietary choices	Minimizing processed foods Drinking approximately two liters of water daily Consuming a variety of fruits and vegetables
Proactive health care	Establishing a relationship with a health-care provider Getting regular check-ups Preventive health care/testing Maintaining a consistent sleep schedule Reducing stress
Minimizing risky activities	Limiting alcohol consumption Avoiding nicotine Minimizing risky physical activities

TABLE 3.2 **Maintenance of Physical Wellness**

Mental, Emotional, and Social Wellness

The state in which a person feels satisfaction and can effectively cope with changes in their mental, emotional, and social health status is considered their **mental, emotional, and social wellness**. Emotional wellness requires the ability to identify, express, and manage the full range of emotions (Melnyk & Neale, 2018). Social wellness is based on the person's interaction within their social system, meaning social wellness requires social support, relationships with respect and trust, and social connections that assist with stressful or challenging situations. "Mental wellness" refers to a state in which a person can effectively cope with the stressors in their life while maintaining relationships and contributing to their community.

The promotion of mental, emotional, and social wellness requires nurses to know the context in which the person is living. Mental, emotional, and social support are not always available given the patient's situation. If mental, emotional, or social support is not present in a patient's life, the nurse can help identify the need and provide resources to help the patient meet those needs. For example, a person of color may not be able to achieve emotional or social wellness in a racist environment that continually makes them feel unsafe. Providing this person with counseling and social support can help provide a safety net until the patient can improve their level of mental, emotional, and social wellness. The health-care system can also provide coping skills education and emotional intelligence education, and can connect the patient to social groups that can provide other types of support.

Spiritual Wellness

An important component of the holistic wellness model that should not be overlooked by nurses and other health-care professionals is **spiritual wellness**, the optimal functioning of a person's spirit. This type of wellness is subjective and individualized to each person and, therefore, cannot be provided through a one-size-fits-all model. Spirituality can be just as important to holistic health as other aspects such as physical or emotional health. A person's **spirituality** is what gives them a sense of meaning and purpose in life. Achieving spiritual wellness involves actively making choices that improve the capacity for creating a fulfilling spiritual life. The aspects of life that define spirituality include religion, faith, values, beliefs, principles, and morals (Ghiya, 2019). The organized system of beliefs that reflect a person's approach to or understanding of spirituality is considered **religion**, but spirituality is broader than religion, and a person may be spiritual without being religious (Dossey & Keegan, 2020).

Supporting the spiritual health of patients requires conversations about spirituality and understanding of the individual's spiritual history, symbols, beliefs, and practices. For example, if the nurse is promoting the health and well-being of a member of the Muslim population, it would be important to whether the person prays and, if they do, at what times of day in order to coordinate care around their prayer times. This type of accommodation should be looked upon as supporting the spirituality of the patient rather than an inconvenience of scheduling.

Spirituality is a sacred connection to something; it can be a connection to a sacred source (like God, Tao, or Allah), nature, others, or self. Health promotion regarding spirituality must provide for the connections to these things to be successful. Planning and building a sacred garden in an urban housing complex would support the spiritual

connection to nature for the people who live there.

Ways to promote the spiritual health and well-being of patients include teaching communication skills, active listening, storytelling, encouraging regular practice of meditation (including prayer or centering), fostering connections, facilitating religious rituals, engaging in art, and allowing for periods of restful peace. Any of these recommended activities can support a patient's spiritual health and well-being, but they may need guidance in how to incorporate them into their schedules or how to do them.

If spirituality is overlooked in a health-care situation, then the patient has not reached true holistic wellness and healing. Spirituality is an area in which nurses are challenged (and sometimes unable, due to lack of knowledge) to provide culturally competent and culturally relevant spiritual guidance. To provide holistic health care, more focus on educating nurses and other health-care providers about their roles in spiritual wellness is needed.

REAL RN STORIES

Nurse: Bethannie
Years in Practice: Twenty-seven
Clinical Setting: Community-based parish hospital
Geographic Location: Oregon

At the end of my career, I began a parish nursing role. I specialized in delivering a comprehensive approach to nursing care within a faith-based community setting. As an integral member of the ministry team, I collaborated closely with religious leaders to enhance the holistic well-being of our community members. My community-wide interventions span a wide spectrum of initiatives aimed at promoting health and wellness. I developed programs that encompassed awareness and wellness, such as a children's vaccination program. I coordinated my efforts with community health services, health counseling, and facilitated referrals to available resources. I found myself being the advocate for community needs. My role included tasks such as volunteer training, conducting health screenings, facilitating support groups, and conducting educational classes on health-related topics. Through these multifaceted approaches, I was able to play a pivotal role in fostering the overall health and vitality of my faith community. Becoming a parish nurse was the highlight of my career.

3.2 Strategies for Improving Healthy Habits

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe strategies for helping to improve physical health
- Describe strategies for helping to improve psychosocial health

Recent changes and trends in health-care access, information, and technology, including incorporating the consequences of the COVID-19 pandemic, have emerged as standard practice. Nurses' use of social media, telehealth, and other online platforms to educate patients and promote health have increased.

During the pandemic, people heightened their focus on physical health by adopting preventive measures like hand hygiene and mask-wearing and prioritizing immune-boosting behaviors such as sleep and exercise. The pandemic also exacerbated mental health challenges due to stressors like fear, economic instability, and social isolation. Coping with changes in routines and experiencing grief added to emotional strain. Individuals adapted by reassessing priorities, spending more time with family, and embracing self-care practice. Communities responded by supporting at-risk groups and promoting mental health awareness through initiatives like online support groups and education campaigns.

Physical Exercise

Physical exercise decreases the risk for obesity, chronic illness, and age-related changes. Physical exercise can not only prevent disease, but it can also help with stress management and improve well-being. It is important to provide options to people when promoting physical exercise because finding a physical exercise regimen that is enjoyable increases the likelihood that the person will continue to engage in the activity.

There are four basic components required for a well-balanced physical exercise routine (Dossey & Keegan, 2016). They are:

1. flexibility
2. muscle strength
3. cardiorespiratory endurance (aerobics)
4. postural stability

Each patient should be encouraged to engage in all four components of physical exercise to provide the most health benefits. Doing so keeps patients from getting bored with their exercise routine and allows them to find exercise modalities that they enjoy. Table 3.3 provides more details on the four components of well-balanced exercise routines.

Component	Examples	Benefits
Flexibility	• Yoga • Stretching • Pilates	• Decreases risk for injury • Improves joint movement • Increases blood flow
Muscle strength	• Resistance bands • Free weights • Isometric training • Polymetric training	• Increases endurance • Protects bone health • Improves sleep quality
Cardiorespiratory endurance	• Running • Jogging • Swimming • Stair climbing • Cycling	• Increases stamina • Strengthens cardiac and respiratory muscles • Boosts mood
Postural stability	• Stability ball • Balance training • Range of motion • Gait training • Running in place	• Prevents falls • Improves balance • Decreases fatigue • Enhances motor skills

TABLE 3.3 **Examples and Benefits of the Four Basic Components of a Well-Balanced Exercise Routine**

Exercise has cumulative benefits, meaning that any effort to exercise is an improvement from the baseline and provides positive health effects. This is important for patients who may have tried to implement exercise routines in the past and were unsuccessful. Encouraging patients to incorporate small amounts of exercise into their routines and then expanding those efforts is less intimidating for a person with a sedentary lifestyle.

Nurses should avoid approaching the subject of physical exercise from a shaming and blaming standpoint. Shaming a patient does not improve exercise efforts. Exercise should be discussed in a nonjudgmental way that allows the patient to view physical exercise as a part of their lifestyle rather than a punishment for previous lifestyle choices. The challenges of physical exercise should be discussed with patients of all ages, cultures, and weights, not just patients identified as having obesity.

Mindful Self-Care

Mindfulness and self-care are essential to the holistic health and well-being of patients and their communities. A **mindfulness practice** allows a person to quiet the mind and focus their awareness on the present state of being. A **self-care practice** promotes the health and well-being of the individual and gives time for patients to focus on what

their body needs. Mindful self-care suggests that a person quiet the mind, becoming aware of the current state of their health and well-being, and identify ways to promote or improve the state of well-being through self-care. promote or improve the state of well-being through self-care.

CLINICAL SAFETY AND PROCEDURES (QSEN)

Mindfulness

An individual's state of awareness, achieved through personal focus, being in the present, and/or meditation is called mindfulness. Paying attention and being fully cognizant of a situation without extreme reaction can provide calming and centering. The practice of mindfulness dates back to ancient times and was originally grounded in Buddhist and Hindu traditions. Practicing mindfulness can improve a person's overall sense of well-being and mental health. In addition, the use of mindfulness techniques—being fully present in the moment and being aware of one's surroundings, environment, and senses—is another protective factor that reduces stress and thereby lowers risk factors for mental illness. Examples of mindfulness techniques include meditation and keeping gratitude journals, instead of ruminating about the "what-ifs." By mastering the capacity to pay attention in the present moment and the ability to recognize the reality of our complex lives, the nurse can address all QSEN competencies and then is able to skillfully provide the patient with the same set of knowledge and skills.

Mindful self-care can take many forms, such as meditation, journaling, or breathing exercises. These activities are as varied as the patients who practice them and should be individualized for the patient's optimal idea of well-being. Whatever the activity, it should encourage development of one's inner consciousness, support well-being, and focus on creating balance and satisfaction in life. Mindful self-care should be practiced daily in a comfortable environment. If the patient is having trouble working mindful self-care practices into their daily routine, some quick options include taking deep breathing breaks throughout the day, journaling for 10 minutes a day, joining a mindful/self-care group like a drumming circle (Figure 3.4), planning a mindfulness or self-care retreat, or finding a friend who has a similar goal and practicing together.

FIGURE 3.4 Participation in a drumming circle can help to promote mindfulness and well-being. (credit: "Drum circle" by Selena N.B.H./Flickr; CC BY 2.0)

Work-Life Balance

Work-life balance can be achieved through the creation and maintenance of healthy boundaries. A **healthy boundary** is a guideline that people set to regulate relationships. In this case, it is the relationship between work

and home life where people need to achieve a healthy balance. Examples of healthy boundaries regarding work include not checking email after work hours, working only during "work hours" (this will depend on the person's work schedule), or not being available for calls or meetings on weekends. Healthy work boundaries are more difficult to set for people who work from home, have on-call hours, or are in a management or salaried position. Completing a thorough assessment of how work and home life feel out of balance will help you and the patient identify where boundaries need to be drawn.

Work-life balance is a common cause of stress for patients. Research indicates that those who have small children, a new marriage or job, caregiving responsibilities, or any number of other responsibilities are more susceptible to work-life challenges (Rathnaweera & Jayathilaka, 2021). If there are things that the patient can cut out of their schedule to make it less stressful, it is recommended to do so according to how important each activity is to them. For example, if the patient is working a full-time job, has children, works part-time at a senior center, and volunteers for a local charity, the patient can identify which of these are the least important and cut it out of their schedule to decrease the demands on their time. This would require the patient to consider the advantages and disadvantages of each activity and determine which activity, if removed, would decrease their stress level to a manageable level. When creating a healthy work-life balance, the patient needs to learn to prioritize and set boundaries to create the healthiest scenario for themselves. The nurse's role is to help the patient identify when there is a work-life imbalance, empower the patient to take steps toward achieving work-life balance, and provide resources to make the process successful. Less stress can lead to more productive work and feelings of being more present in one's home life (Rathnaweera & Jayathilaka, 2021).

Healthy Eating

The food that people consume is the basis for all the energy needed for the body to function normally. Foods should be nutrient dense and satisfying. Fad diets or unproven diet plans should be avoided. When educating patients, recommend simple, whole-food options. The most nutritious diets contain a variety of fruits, vegetables, healthy fats, and lean proteins (Figure 3.5), whereas the least nutritious diets contain large amounts of processed ingredients, high sugar content, and large amounts of unhealthy fats.

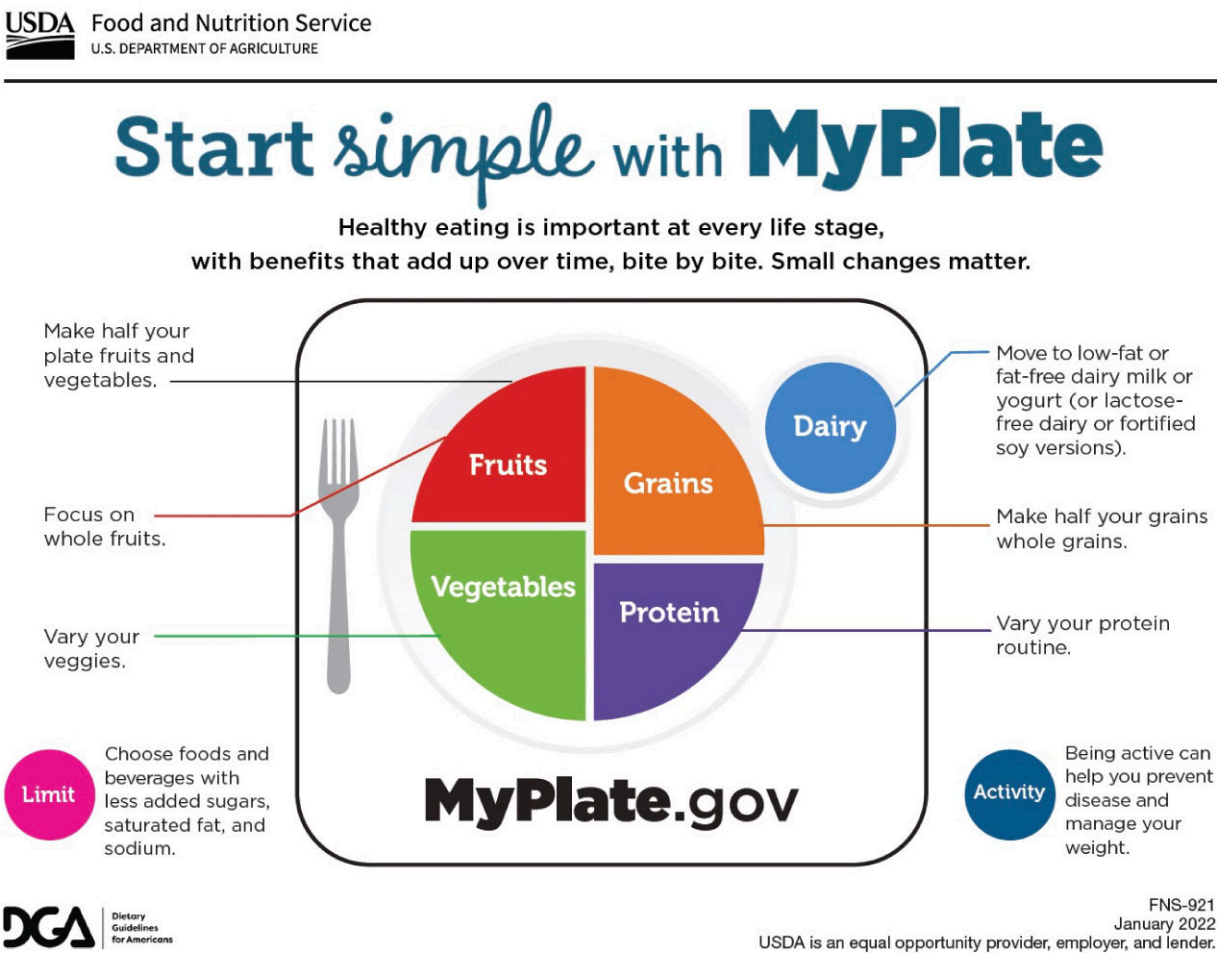

FIGURE 3.5 The U.S. Department of Agriculture created MyPlate to help promote healthy eating. (credit: Untitled by MyPlate.gov/U.S. Department of Agriculture, Public Domain)

Promoting healthy eating habits starts with educating the patient. It is also important to encourage small, manageable changes in eating habits, such as portion control. These small changes can be managed in the long term rather than trying to change everything all at once. Some other examples of small changes include swapping out sugary drinks for water, eating one meatless dinner each week, and eating freshly prepared meals instead of pre-made processed meals.

Sleep Hygiene

The rituals a person practices surrounding their bedtime and sleep routine is called **sleep hygiene**. The sleep routine is an underutilized health-boosting practice. The benefits of having a healthy sleep hygiene routine include longer, more restful sleep, less daytime sleepiness, and more energy.

A healthy sleep hygiene routine is one that is consistent. Many people do not have the ability to maintain a consistent schedule due to work or other obligations, but sleep routines should be prioritized as much as possible. Consistently going to bed and waking up at the same time promotes the natural rhythm of the body. Avoiding stimulants, like nicotine and caffeine, prior to going to bed will allow the body to fall asleep more readily. If a patient is having trouble sleeping, identify nonpharmacological sleep aids and avoid over-the-counter options. Nonpharmacological sleep aids include meditation, diffusing lavender or chamomile essential oils, massage, and a relaxing bath before bed. Aspects of a healthy sleep hygiene routine include exercising during the day to expend extra energy, adjusting bedroom temperature, avoiding screens (TV or phone) in bed, darkening the room while sleeping, and making the room quiet. Doing the same ritual before lying down to sleep is also helpful, like bathing, brushing teeth, and plugging in the phone.

Social and Family Support

Encouraging patients to seek social and family support can cause hesitation in some individuals who view the act of

seeking help as a weakness rather than a strength. Identification and introduction to social support systems within their communities are important to improve overall health outcomes. Assisting patients with these difficult conversations with family members is an appropriate nursing role and will improve the chances of opening communication between the patient, family members, and identifying support people.

Lifestyle Changes

What motivates an individual to make lasting lifestyle change? How can a nurse influence an individual so profoundly that they make the necessary changes to improve their health? Examining these questions assists nurses with goal development and care when assisting patients with successful lifestyle changes.

A nurse's role in the promotion of lifestyle changes in patients is that of coach or facilitator. To facilitate changes in lifestyle, a nurse must assess the patient's daily practices. This assessment, called a **lifestyle assessment**, identifies a patient's everyday patterns of living and establishes how those activities influence the patient's overall health (Pender et al., 2018). Once the assessment is completed, the nurse can determine which area presents the most need for the patient. Together the nurse and patient can create a plan of action that will help the patient make specific lifestyle changes. This plan includes self-determined goals, feedback on progress, identifying and responding to challenges, and determining success.

Lifestyle health promotion activities can be divided into two categories: preventive and reactive. A **preventive lifestyle health-promotion activity** is geared toward preventing adverse health outcomes, whereas a **reactive health-promotion activity** focuses on stopping poor lifestyle behaviors that are known to lead to disease. For instance, a preventive lifestyle health-promotion activity is planned to increase consumption of a healthy diet, this healthy diet will prevent development of disease or illness. A reactive lifestyle health-promotion activity would focus on a group of patients diagnosed with diabetes. The identified goal would be making appropriate changes in the diet to prevent complications of diabetes.

Lifestyle changes do not have to be extreme; in fact, the change of small behaviors may be more sustainable than making a complete overhaul. Small scale lifestyle behaviors that can lead to improved health include things like:

- eating more fruits and vegetables
- substituting water for sugar-filled drinks
- avoiding processed foods
- eating out less often
- replacing unhealthy snacks with healthier options
- incorporating stretching into the daily routine
- proactively staying up to date on current vaccination recommendations
- minimizing noise levels when possible
- removing electronic devices from sleeping area
- avoiding electronic devices one hour prior to sleeping
- engaging in social activities with friends or relatives
- using a reflection journal for 5–10 minutes each day (Gorstein, 2019)

Reactive lifestyle health-promotion activities are essential to improve the quality of life for patients who are already experiencing health concerns. Health-promotion activities focused on smoking cessation, reducing alcohol consumption, avoiding illicit drug use, safe sexual practices, and heart-healthy diets are examples of reactive lifestyle health-promotion activities.

Community Involvement

A **community** is the group of people of which an individual is a part. A community is a collective of people who have something in common or "belong" together. They share values, have social norms or traditions, have established communication patterns, and work together to solve problems (Pender et al., 2018). Being a part of a community is an important aspect of human existence; it can determine a person's health status through the social norms established by that community. Social norms in a community can influence how often a person exercises, how they engage in self-care, what a person eats, and their level of emotional intelligence.

Humans are not meant to be solitary beings, so being part of a community is essential to the holistic health and

well-being of an individual. Communities provide their members with resources and relationships that can promote optimal health, decrease stress, and improve mental health (Salfas et al., 2019). The improved health of an individual community member helps to optimize overall community health.

The role of health promotion in a community setting extends from each individual community member to the whole community. Community health promotion can be used to change the entire community's health status. Examples of Healthy People 2030 goals that could be improved by community health initiatives include increased screenings for oral health, decreasing drug overdose deaths, decreasing suicide rates, and decreasing infant death rates (U.S. Department of Health and Human Services, 2021). The community must recognize that the health goal is important to the health of the community members to buy into the health-promotion campaign.

3.3 Challenges Throughout the Lifespan

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss health challenges encountered with young adults
- Discuss health challenges encountered with middle-aged adults
- Discuss health challenges encountered with the older adult population

As individuals grow and develop throughout their lives, health challenges and health-promotion opportunities change. The type of health issues and methods of health promotion must take into consideration a wide range of factors, including health literacy, physical limitations, motivations, family dynamics, support systems, and access to health services. Creating health-promotion activities with these factors in mind can increase the success of the activity.

Young Adults

The young adult age group is 18 to 35 years old. Erik Erikson (a human growth and development theorist) described the goal of this age group as intimacy versus isolation and summarized the challenges for this group as trying to achieve affiliation, community, and love (Erikson, 1995). The major events in a young adult's life include attending college or career training, entering the workforce, living independently for the first time, navigating a serious intimate relationship, becoming a parent, and making the adjustment to adulthood (Edelman & Kudzma, 2022). Accidental injury, via motor vehicle accidents primarily, is one of the leading causes of death in the young adult age group (CDC, 2024). When providing health promotion and patient education to young adults, nurses should keep in mind possible financial constraints (students or entry-level employees) and focus on building a healthy foundation for optimal health as they age (Table 3.4).

Category	Education Topic
Nutrition	• Healthy diet • Weight management
Substance use	• Alcohol use screening • Tobacco use screening • Illicit drug use screening
Mental health	• Depression screening • Suicide prevention

TABLE 3.4 Health-Promotion Topics Relevant to Young Adults (White et al., 2018)

Category	Education Topic
Safety/violence	• Family/intimate partner violence • Vehicle safety: seatbelts, helmets • Bullying • Guns
Reproductive health	• Pregnancy • Sexually transmitted infections • Birth control
Cancer screenings	• Testicular • Breast • Skin • Ovarian
Infectious diseases	• Recommended vaccinations

TABLE 3.4 **Health-Promotion Topics Relevant to Young Adults** (White et al., 2018)

Middle-Aged Adults

The middle-aged adult group comprises people ages 35 to 65 years old. The Erikson growth and development stage applied to the middle-aged adult group is generativity versus stagnation, which focuses on their need to be productive in society and make an impact on the world (Erikson, 1995). Most middle-aged adults are creating or raising a family and may also be needed to assist in the care of aging parents. Being in between these two groups and having to provide both groups with care earns the middle-aged adult group the nickname the "**sandwich generation**" (Edelman & Kudzma, 2022).

CULTURAL CONTEXT

Chronic Kidney Disease

For 37 million individuals in the United States, chronic kidney disease (CKD) is an everyday reality (Phillip et al., 2022). One of the identified social determinants of health, food insecurity, plays a significant role in the progression of CKD. Dietary choices directly impact complications such as high blood pressure. Notably, food insecurity is more prevalent among Black and Hispanic population groups (Phillip et al., 2022).

In the realm of CKD and associated diagnoses of high blood pressure, patient education and health promotion are indispensable for fostering self-management of the disease processes. While educating patients about healthy food choices is crucial, it becomes complex when dealing with patients experiencing food insecurity, influenced by factors such as food deserts and socioeconomic status. In these instances, nurses need to be mindful of tailoring information to the patient's specific circumstances.

Addressing food insecurity involves identifying community resources that can provide healthy food options for affected patients. Additionally, a critical aspect of patient education for those with CKD and high blood pressure is the importance of a low-sodium diet. Unfortunately, readily available and affordable foods like potato chips, canned goods, processed meats, and snacks are often high in sodium. This poses a challenge for individuals facing food insecurity who may have limited access to healthier alternatives. The relationship between food insecurity and health conditions highlights the challenges faced by individuals striving to make healthy choices, particularly those contending with severe health conditions alongside food insecurity.

Health promotion for middle-aged adults should focus on disease prevention and lifestyle modifications for health

optimization. The most common causes of death for middle-aged adults include cardiovascular disease, cancer, and unintentional injuries (CDC, 2024). Because of the large amount of modifiable risk factors associated with these causes of death, health promotion for the middle-aged adult is of great importance. A factor that a person can control that increases the probability that the person will get a disease is called a **modifiable risk factor**. An example of a modifiable risk factor is diet, whereas race, age, and genetic make-up are nonmodifiable risk factors. A **nonmodifiable risk factor** is a factor that is out of a person's control. Identifying modifiable risk factors and educating patients about them is part of health promotion.

Self-destructive lifestyle behaviors such as cigarette smoking, alcohol and caffeine consumption, and unhealthy eating have become more of a problem for middle-aged adults (Eldeman & Kudzma, 2022). Middle-aged adults start to see the effects of these self-destructive lifestyle behaviors on their bodies and may seek out health-promotion information related to these issues (Table 3.5). Still, it is important for nurses to proactively promote lifestyle behavior changes as appropriate regarding these self-destructive behaviors.

Category	Education Topic
Nutrition	• Low saturated-fat diets • Increasing calcium and vitamin D intake • Caffeine reduction • Low sodium diet
Elimination	• Constipation prevention • Urinary continence maintenance
Physical activity	• Increasing physical activity
Sleep	• Improving sleep hygiene • Insomnia prevention • Sleep apnea awareness
Cognition	• Maintenance of intellectual ability • Cognitive decline awareness
Sensory changes	• Identification of vision changes • Eye diseases common with aging
Stress	• Management of stress
Menopause	• Awareness • Identification • Management
Caregiver role	• Role strain prevention
High-risk lifestyle behaviors	• Smoking cessation • Caffeine reduction • Alcohol consumption management

TABLE 3.5 **Health-Promotion Topics Relevant to Middle-Aged Adults** (Edelman & Kudzma, 2022)

Category	Education Topic
Cancer screenings	• Breast • Colorectal • Cervical • Prostate • Smoking-related cancers: lung, esophageal, mouth, laryngeal
Oral health	• Gingivitis prevention • Improving dental hygiene • Avoiding dental decay

TABLE 3.5 Health-Promotion Topics Relevant to Middle-Aged Adults (Edelman & Kudzma, 2022)

Older Adults

The older adult age group, ages 65 years and older, is the fastest-growing age group (Edleman & Kudzma, 2022). The growth and development stage associated with older adults is integrity versus despair, which suggests that older adults are focused on whether their life has provided them personal satisfaction or has been wasted (Erikson, 1995). The mindset of this age group determines how engaged they will be with health promotion. An older adult who is satisfied with their contributions to society may have more motivation to maintain optimal health than an individual who feels like their life has been a waste of time and energy. People in the older adult age group are often finished raising kids, have retired from jobs, and are adjusting to a new lifestyle. A social determinant of health that is applicable to this age group is poverty since many older adults who are not working depend on Social Security benefits as their only income. Older adults have been found to have poor health literacy, which means that they may not readily comprehend or understand health concepts (Stewart, 2020).

LIFE-STAGE CONTEXT

Meals on Wheels

America's Meals on Wheels Program is a network of 5,000 programs across the nation that provide older adults with healthy meals to help decrease hunger and isolation (Meals on Wheels America, 2023). This rapidly growing population is considered at risk due to their fixed incomes (the inability to make more money), compromised health, and higher risk for malnutrition. Meals on Wheels America delivers 251 million meals a year to older adults. It improves their health, makes them feel more secure, and allows them to live independently for longer.

(Meals on Wheels America, 2023).

Falls are the most common cause of injury in older adults (CDC, 2023a). Fall prevention is crucial for older adults because falls are a leading cause of injury and loss of independence among this demographic. As individuals age, changes in balance, vision, and muscle strength increase the risk of falls. Implementing fall prevention strategies are essential, such as regular exercise to improve balance and strength, home modifications to reduce hazards, and medication management to minimize side effect that could lead to falls. By addressing fall risk factors, older adults can maintain their independence by reducing the likelihood of fall-related injuries that may result in hospitalization or long-term care placement.

Cognitive stimulation is another vital health-promotion topic for older adults. As individuals age, cognitive decline becomes more common, impacting memory, reasoning, and decision-making abilities. Engaging in activities that stimulate the brain, such as puzzles, reading, socializing, and learning new skills or hobbies, can help preserve cognitive function and delay the onset of cognitive decline or dementia. By promoting cognitive stimulation, older adults can maintain their independence by preserving their cognitive abilities, allowing them to continue living actively and autonomously for longer periods. Additionally, maintaining cognitive function enhances overall well-being and quality of life, enabling older adults to remain engaged and fulfilled in their daily activities and

relationships

Health promotion for older adults should also focus on preventing new diseases and managing their chronic diseases (Table 3.6). Older adults are at increased risk for developing diseases like dementia, heart disease, type 2 diabetes, arthritis, and cancer (CDC, 2023b). Other topics to consider for health promotion in older adults include warning signs of dementia, caregiver wellness, screening and prevention of disease or disability, promotion of independence, and promotion of physical activity (CDC, 2023b).

Category	Education Topic
Nutrition	• Food insecurity • Bone health
Elimination	• Constipation prevention • Urinary continence maintenance
Physical activity	• Maintaining physical ability • Promotion of independence • Pain prevention/alleviation
Cognition	• Maintenance of intellectual ability • Cognitive decline awareness • Dementia/Alzheimer disease risk awareness
Sensory changes	• Identification of vision changes • Eye diseases common in aging
Community	• Encourage active roles in the community
Chronic disease	• Risk reduction • Prevention and management

TABLE 3.6 Health-Promotion Topics for Older Adults (Edelman & Kudzma, 2022)

The National Council on Aging presents the Center for Healthy Aging for Professionals. This resource provides evidence-based health-promotion information (https://openstax.org/r/77EvBasHeaInfo) with the goal of helping older adults live healthier lives.

3.4 Purpose of Health Education and Patient Teaching

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define the objectives of health teaching
- Discuss the facilitators and barriers to patient education
- Describe resources utilized in patient education

The purpose of health education is to empower individuals to make the best behavior choices to improve their quality of life, promote adherence to prescribed interventions and medications, increase the understanding of their

conditions or treatments, and maximize patient satisfaction (Gusman, 2022). Nurses are the largest group of health-care providers, with the most interaction with patients, putting them in an optimal position to educate patients (AACN, 2023).

Health Teaching Objectives

Health teaching should occur at every encounter between the nurse and patient. Each encounter is an opportunity for health promotion through primary, secondary, or tertiary prevention. The model of incorporating unique learning styles, educational background, and assessment to facilitate increasing patient health knowledge levels is considered **health teaching**.

Patients will inevitably be diagnosed with new conditions, be prescribed new medications, or be introduced to new health-promotion activities as they move through their life. When a new condition is diagnosed, it is important to start the task of educating the patient about management of the condition and its potential complications. Discussing complications of the condition provides the motivation to manage the condition to the best of the patient's ability. The more knowledge about the health condition that the patient has, the better they are at self-management, and this improves their quality of life (Lord et al., 2021).

Medication Education

Medication education is critical for patients to understand how to safely self-administer without complications. Medications taken incorrectly can cause side effects, adverse events, or even death. Medication errors cause unexpected hospital admissions, increased lengths of stay, and increased health-care costs (Aldhafeeri & Alamatrouk, 2019). Medication compliance and the importance of taking medications as prescribed for safety and efficacy should also be included in the provided education. When teaching a patient about medications, the nurse must explain the different names, such generic and trade names. Each medication has a generic and a brand name, and it is important that the patient understands this because they could inadvertently take two of the same medications if given bottles with name variations. Another essential aspect of medication education is the medication's known side effects. A **side effect** nonlethal but irritating health effect of a medication, and the patient needs to know that it is possible to have them after taking the medication. Conversely, an **adverse effect** (or complication) is a medication-caused issue that is more serious, may be life threatening, and should be reported to the prescribing provider. The patient should be taught the common adverse effects of a medication so that they report the issues and avoid devasting consequences of taking the medication.

A **contraindication** is a situation in which a medication should not be taken by the patient for a specific reason, like another disease process or because of another medication. A common contraindication is pregnancy, meaning that if the patient is pregnant, trying to get pregnant, or becomes pregnant, they should not be taking the medication. Knowing the contraindications of medications can help the patient avoid harm related to the contraindicated aspect of their health. Medication safety is a complex topic and may be overwhelming to the patient, especially if they have multiple prescription medications. It is vital that the nurse not rely only on pharmacy handouts to educate the patient regarding important medication safety information. During each encounter, the nurse should address any patient or family concerns regarding the medications.

Because medication safety is an extremely important safety concern for people of all ages, nurses are required to complete a medication reconciliation process when a patient encounters the health-care system. The goal of a **medication reconciliation** is to prevent common medication errors through a comparison process, making sure the medications that the patient is taking are the medications that have been prescribed, and compiling an accurate list of current medications (Anazi, 2021). The medication reconciliation process has helped to prevent medication errors such as omissions, duplications, dosing errors, or drug interactions (Anazi, 2021).

Discharge Teaching

The nursing intervention that allows the patient to understand how to care for themselves at home after an acute health issue is called **discharge teaching**. Hospitalization has occurred due to a change in the health status of the individual, whether that change was an illness or surgery. Changes in the health status create a knowledge deficit for the patient, and discharge teaching is designed to bridge the knowledge gap so that the patient can adequately care for themselves at home and not be readmitted to the hospital for further complications. Discharge teaching includes education about any new medications the patient has been prescribed, any new interventions that the patient must perform (dressing changes, medication, etc.), what complications may occur, when and how to report any

complications, and when follow-up appointments with providers should take place. The Joint Commission (2018) requires that discharge education include follow-up appointment information, that the patient or caregiver be given a hard copy of any discharge documents, and that the process be thoroughly documented in the medical record. The nurse must not forget to measure the patient's successful understanding or need to re-teach, reinforce, and re-educate the patient before discharge.

INTERDISCIPLINARY PLAN OF CARE

Interdisciplinary Care for Patient Discharge

Nurses work with an interdisciplinary team and coordinate care for patients being discharged from the hospital. The following are examples of these team members:

- The nurse is responsible for providing discharge instructions and education.
- A respiratory therapist is responsible for providing post-discharge instructions for any pulmonary machines, such as a sleep apnea machine. They provide the patient with education on breathing treatments and pulmonary exercises such as an incentive spirometer.
- The provider orders the discharge of the patient and any specialty referrals needed to manage the patient's care once discharged.
- The case manager coordinates ancillary departments needed to sign off on the patient's plan of care, such as a wound care specialist or dietician and coordinates resources and follow-up for the family once the patient is discharged.

Barriers to and Facilitators of Patient Education

Not all patients have the same level of access to health-care or patient education. Barriers to patient education include reading level, comprehension level, spoken or written language barriers, cultural barriers, learning style, motivation to learn, and health literacy levels (Gusman, 2022). A thorough history and assessment can identify many of these barriers, and a plan to circumvent them can be made. For example, if a patient has a third-grade education level, then the nurse can create handouts that are at an appropriate reading level for the patient to refer to at home.

Another barrier to patient education is **health literacy**, which is the level of knowledge that an individual has about health care, health issues, and overall health and well-being. Having a low health literacy level can affect the amount of knowledge that a person has about health in general, and especially their understanding of disease processes or treatment options. Patients at risk of having low health literacy levels include those with language barriers, some disadvantaged groups, and older adults (Gussman, 2022). Low health literacy can account for a patient's noncompliance with prescribed care, missed appointments, and medication errors. Researchers found that approximately 65 percent of patients admitted to the hospital did not understand the treatments they were receiving or why they had been admitted to the hospital (Wang & Lo, 2021). For patients with low health literacy, it is essential to present information in a clear, easily understandable format and avoid complicated medical terms or jargon. Nurses should always evaluate patient understanding using methods, such as teach-back.

LINK TO LEARNING

Health Literacy

The definition of health literacy (https://openstax.org/r/77HealthLitDef) was updated and released with the U.S. government's Healthy People 2030 initiative.

All nurses are responsible for providing patient education and health promotion, but some specific roles within nursing focus on these objectives directly. Job roles that focus on patient education promote positive patient outcomes and improve patient satisfaction. A nurse navigator or patient navigator role improves the communication between patients and providers, improves the patient's compliance with appointments and treatments, and works to remove any barriers the patient may have to receiving the care that is needed (Doyle, 2019). Another nursing role

that facilitates patient education is the case manager or care coordinator. Care coordinators can bridge the gap between the provider's prescribed plan of care and the patient's individual needs and preferences. There are medical roles for specific types of education, such as a diabetes educator or renal transplant educator. Both educator roles focus on a specific patient population and specific education content.

Resources for Patient Education

Topic-specific education resources are available from health-care associations specializing in specific types of health. For instance, if a patient has a heart condition, there are many free patient education resources from the American Heart Association. These resources are organized according to disease process and are available on their website. There are a multitude of health-care associations that provide free educational resources, including the American Stroke Association, the American Cancer Society, and the American Diabetes Association. Patients can be referred to resources like these for their personal use. Nurses can print relevant handouts for patients or obtain patient education ideas from these resources.

Not all educational resources contain legitimate and up-to-date information. The nurse must be able to identify sources of quality information for teaching and referral. Credible resources are relevant to the patient's situation, backed by research, and contain information written in an easy-to-read format.

Reliable Online Information

Read this article about finding reliable health information online (https://openstax.org/r/77ReliableHeInf) on the National Institutes of Health's website.

3.5 Strategies for Optimal Patient Education

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explore visual methods for delivering patient education
- Explore audio methods for delivering patient education
- Discuss technology utilized in patient education
- Summarize methods of educating patients with a different language

Patient education can empower a patient to make more informed health-care-related choices and, through those choices, improve or maintain their quality of life. Patient education should be a well-thought-out and planned encounter, not an afterthought of the nurse-patient encounter. Providing quality patient education requires nurses to understand the content they are teaching and understand how to teach it for the best results.

Patient teaching requires clear communication and often takes time to achieve the optimal level of patient knowledge. The time devoted to patient education includes preparation and implementation of the education plan. Nurses can use education templates to assist with typical or recurring patient education needs. For example, if a nurse works on a stroke care floor, the patients and caregivers will need to understand follow-up care for strokes. This stroke education can be structured so that each patient receives the same teaching points, and the nurse can individualize teaching on a patient-by-patient basis, such as using the patient's native language. This allows for the most important educational points to be covered within the template and individual needs to be met through additional individualized content.

Audio/Visual Methods

A **visual method** of communication involves patient education material that has a visual component, such as posters, graphics, brochures, handouts, and maps. Educational materials that require the patient to read content should be written at or below a sixth-grade reading comprehension level (Baumann et al., 2023). Visual education materials are convenient for the educator and can serve as reinforcement of face-to-face education.

An **audio method** of communication involves patient education material that has an audio component, such as videos, audio recordings of patient education materials, musical or lyrical lessons, and informational podcasts.

Audio patient education options are convenient for those with visual impairments or an inability to read. Audio methods of patient education materials need to be presented in a logical format that clearly identifies the purpose of the educational material and does not distract from the needed patient information (Shoemaker et al., 2020).

Kinesthetic Methods

Many patient education situations require patients to learn a skill or maneuver that is specific to their health issue. For example, a postoperative patient will require education on how to change a wound dressing. The most effective education for this type of skill is hands-on learning, also known as **kinesthetic learning**. A patient who can perform a skill with the supervision of a nurse will have more confidence and understanding of the skill and therefore will perform the skill as prescribed instead of improvising. The nurse will demonstrate the skill for the patient, then require the patient to return-demonstrate the same skill to prove their understanding, which is a learning evaluation called the **teach-back method**. This provides practice for the patient, and an opportunity for the nurse to identify any problems with the technique used to perform the skill.

Nurses can allow a patient to return-demonstrate skills in almost any nursing setting, including hospitals, clinics, home-care settings, and long-term care facilities. The return-demonstration technique can also be used to educate a caregiver on the proper way to perform caregiving tasks when the patient is home. Some health facilities have patient learning centers where learning, practicing, and demonstrating health-related skills allows patients and their families to become instrumental in their own care.

Technology

Technology and the internet have increased access to health-care information for patients. It is extremely important for nurses to be familiar with how to identify a reliable information source and how to refer patients to these expert sources of information. Clarifying reputable sources prevents misconceptions and avoids delays in treatments caused by patients attempting to self-treat through internet research.

There are some drawbacks regarding technology, including that some patients, especially older adult patients, may not have access to technology or the internet, or they have a knowledge deficit regarding how to use technology or access information on the internet (Stewart, 2020). The nurse should assess both the patient's ability to use technology and their access to it before recommending a technology-focused health-promotion modality.

The provision of health-care services remotely through a telecommunications device like a computer or phone is called **telehealth**. Telehealth services have been able to provide patients with a quality of care for many health conditions similar to what they would receive in face-to-face encounters with providers. Telehealth and has also been found to provide some cost savings to both the patient and the provider (Shaver, 2022). Telehealth services include virtual visits, provider-patient conversations, online portals with patient results, sending or receiving messages from providers, appointment scheduling, or prescription requests (Watson, 2020).

The telehealth service that enhances patient self-care management and assists with the patient awareness, self-management of chronic diseases, early detection of acute exacerbations, reduces emergency hospital admissions, and provides more frequent interactions with health-care providers is called **telemonitoring** (Chow et al., 2023). Patient education is not the only objective of this type of telemonitoring program; it also provides the patient with more opportunity to increase awareness of their own disease process. The patient can then participate in managing their own health goals.

Patients Who Speak a Different Language

Patients may have difficulty understanding patient education terms if English is not their native language. Providing patient education in the person's first language will facilitate more comprehension and understanding. Many resources can be found that are premade in common non-English languages like Spanish, French, German, or Arabic.

It is important to provide patients with an interpreter when they do not speak the same language as the health-care provider. It is not adequate to use a lay person as an interpreter because they may not have the health-care knowledge to interpret conversations correctly to the patient. The patient cannot legally consent if the family interprets for them. When a face-to-face interpreter is not available, nurses can easily access language lines, telephone interpretation services, or video interpreter services, a service offered by every accredited health-care facility.

Evaluation of Patient Learning

After completing any intervention, nurses are required to complete an evaluation of the intervention. Evaluation of learning helps the nurse identify whether the patient has any further learning needs or if the education has been effective. The effectiveness of patient education can be evaluated by asking the patient questions to gauge their understanding of the topic, having the patient demonstrate something that they just learned, or having them explain the topic back. The teach-back method is when the learner is required to teach the content back to the educator to demonstrate understanding of the topic. The teach-back method is a relatively quick and accurate way to determine if there are any misunderstandings of the material. Depending on the education setting, a quiz about the topic could be completed by the patient and graded by the educator.

The evaluation stage of patient education is very important because it gives the nurse the opportunity to clarify misunderstandings, re-explain concepts, or even offer alternate education modalities if the patient is having trouble understanding the concept. This step is often overlooked in practice and causes the patients to be released or discharged without the minimum knowledge of how to maintain the plan of care that has been designed for them. It is common for a patient to be labeled as nonadherent (not following provider's orders) when instead they did not actually understand what they were supposed to be doing or how to carry out the task.

The nurse can evaluate a patient's learning by asking them to repeat key facts, quizzing the patient, or asking for a return demonstration of a skill. Once the patient has demonstrated increased knowledge of the subject, the nurse must document that the education session has occurred. Patient education documentation should include the topic of the patient education session, the patient's learning style, the learning goals, a summary of the information or skills taught, the teaching methods used, and an evaluation of the learning (EuroMedInfo, n.d.).

Summary

3.1 Health Promotion and Wellness

- The Health Belief Model highlights factors influencing individuals' decisions to change health behaviors and the significance of individualized, relevant information in promoting behavior change.
- Betty Neuman's health continuum emphasizes the role of health-care workers in intervening at different stages to promote wellness and prevent illness. Primary, secondary, and tertiary prevention strategies can be used to prevent health issues or improve quality of life.
- Ideal health-promotion principles include patient participation, empowerment, and holism.
- A positive health concept can impact a person's well-being.
- Health-promotion activities that consider social determinants and aim for health-care equity are essential. Using the World Health Organization's social determinants of health, patients in need can be identified and targeted for health promotion.
- Wellness is the realization of potential through goal-directed behavior and satisfying relationships.

3.2 Strategies for Improving Healthy Habits

- The COVID-19 pandemic necessitated changes in health-care delivery, prompting nurses to adopt new methods like social media and telehealth for patient education and health promotion.
- Health disparities underscore the need for tailored approaches in health promotion to address underserved populations.
- Health-promotion efforts target various areas, including nutrition; obesity prevention; vaccination compliance; mental health; chronic disease management; opioid addiction, overdose, and death; and domestic abuse.
- Physical exercise is crucial for preventing obesity, chronic illnesses, and age-related changes, with flexibility, muscle strength, cardiorespiratory endurance, and postural stability being key components.
- Mindful self-care practices, such as meditation and journaling, are essential for holistic well-being and promoting awareness of one's health status and ways to improve it.
- Establishing healthy boundaries between work and personal life is vital for managing stress and achieving work-life balance.
- Educating patients about nutritious eating habits and encouraging gradual, sustainable changes is important for long-term health.
- Maintaining good sleep hygiene, including consistent sleep schedules and avoiding stimulants before bed, promotes restful sleep and overall well-being.
- Supporting spiritual health involves understanding and respecting patients' spiritual beliefs, practices, and needs, and incorporating activities like meditation or religious rituals.
- Encouraging social and familial support and community involvement enhances overall health outcomes and fosters a sense of belonging and support.

3.3 Challenges Throughout the Lifespan

- Health challenges and promotion opportunities change as individuals grow and develop throughout their lives.
- Considerations for health-promotion activities include health literacy, physical limitations, motivations, family dynamics, support systems, and access to health services.
- Young adults (18 to 35 years) face challenges related to education, job security, and starting families, with health promotion focusing on building a healthy foundation amid financial constraints and, sometimes, accidental injuries.
- Middle-aged adults (35 to 65 years) experience the "sandwich generation" phenomenon, balancing family care and work responsibilities. Health promotion targets disease prevention, lifestyle modifications, and modifiable risk factors like self-destructive behaviors.
- Older adults (65+ years) grapple with issues like health literacy, poverty, and adjusting to retirement. Health promotion emphasizes maintaining independence, addressing common causes of death like falls, and promoting healthy lifestyle choices and self-care practices.

3.4 Purpose of Health Education and Patient Teaching

- Health education aims to empower individuals for optimal behavior choices, thereby enhancing their quality of

life and promoting compliance with interventions and medications. It also seeks to increase understanding of conditions or treatments and ultimately improve patient satisfaction.

- Health teaching is an integral part of every nurse-patient encounter, focusing on primary, secondary, or tertiary prevention strategies. It addresses new health conditions, medications, and discharge instructions to ensure comprehensive patient education.
- Medication education is crucial for safe self-administration. Nurses educate patients about generic versus brand names, distinguish between side effects and adverse effects, highlight contraindications, and ensure patients understand the importance of medication safety beyond pharmacy handouts.
- Discharge teaching bridges the knowledge gap post-hospitalization, empowering patients to manage their health at home effectively. It includes medication education, instructions on interventions, recognition of complications, and guidance on follow-up appointments.
- Various barriers such as reading level, comprehension, language, cultural differences, learning styles, motivation, and health literacy levels can hinder patient education efforts. Recognizing and addressing these barriers is essential for effective education delivery.
- Nurse navigators, patient navigators, case managers, and care coordinators play pivotal roles in facilitating patient education. Specialized roles like diabetes or renal educators also contribute to tailored and effective education strategies.
- Health-care associations provide valuable resources tailored to specific diseases or conditions. Patients can access these resources online or through printed handouts, offering comprehensive educational support beyond clinical settings.

3.5 Strategies for Optimal Patient Education

- Patient education is crucial for informed health-care decisions and improved quality of life.
- Effective patient education requires thorough planning and clear communication.
- Nurses need to understand the content and use suitable teaching methods.
- Visual aids like posters and brochures, along with audio resources, help with effective communication.
- Kinesthetic methods, involving hands-on learning, are beneficial for teaching practical skills.
- Technology, including telehealth and telemonitoring, expands access to health-care information.
- Disparities in technology access must be addressed to ensure equitable health-care education.
- Providing education in patients' native languages, supported by professional interpreters when necessary, facilitates comprehension.
- Evaluation of patient learning is crucial to assess understanding and address misconceptions.
- Patient education is essential to optimize health-care outcomes and should be integrated thoughtfully into clinical encounters.

Key Terms

action competence learning model critical thinking model that is used in the creation of health-promotion activities

adverse effect (also: *complication*) medication-caused issue that is more serious, may be life threatening, and should be reported to the prescribing provider

audio method patient education material that has an audio component like videos, audio recordings, musical lessons, informational podcasts

collective action competence when action competence is applied to a group, community, or population

community group of people that an individual is a part of

contraindication situation in which a medication should not be taken by the patient for a specific reason

discharge teaching nursing intervention that promotes patient understanding of how to care for themselves while outside of the health-care setting

health a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity

health literacy level of knowledge that an individual has about the health-care system, health issues, and overall health and well-being

health promotion holistic and proactive process of prevention of health issues through which people are empowered to take control of their health-related choices and reach the best possible health status

health teaching model of incorporating individualized learning styles, educational background, and assessment to facilitate increasing patients' level of health knowledge
health-care disparity when a certain group of people have worse health outcomes than other groups of people for no obvious reason
health-care equity equal opportunity for people to achieve their desired health outcomes
healthy boundary guideline that people set to regulate relationships
kinesthetic learning patient education technique that provides hands-on interaction with learners, such as models or practice labs
lifestyle assessment identifies everyday patterns of living and how those patterns influence the individual's health status
medication reconciliation prevention of common medication errors through a comparison process making sure the medications that the patient is taking are the medications that have been prescribed and compiling an accurate list of current medications
mental, emotional, and social wellness state in which a person feels satisfaction with and can effectively cope with changes in their mental, emotional, and social health status
mindfulness practice allows a person to quiet the mind and focus their awareness on the present state of being
modifiable risk factor disease risk factor that the person is in control of; can increase the probability that the person will get the disease
nonmodifiable risk factor disease risk factor that is out of a person's control but increases the probability that the person will get the disease
physical wellness optimal physical function
positive health concept subjective view of one's health status that allows a person to function at optimal levels, cope with life's stressors, and maintain a feeling of satisfaction, even though they experience stressors
preventive lifestyle health-promotion activity activity geared toward preventing adverse health outcomes
reactive health-promotion activity activity that focuses on stopping poor lifestyle behaviors that are known to lead to disease
religion expression of a person's spirituality that is usually an organized, community-based experience
sandwich generation middle-aged group caring for both their own children and their parents
self-care practice promotes the health and well-being of the individual and give time for patients to focus on what their body needs
side effect nonlethal but irritating health effect of a medication
sleep hygiene rituals a person practices surrounding their bedtime and sleep routine
spiritual wellness optimal functioning of a person's spirit, which is subjective and individualized to each person
spirituality concept of what gives an individual a sense of meaning and purpose in life
teach-back method learning evaluation in which the will demonstrate the skill for the patient, then require the patient to return-demonstrate the same skill to prove their understanding
telehealth health care that is provided remotely through a telecommunication device like a computer or phone
telemonitoring type of telehealth that enhances a patient's ability to care for themselves and manage chronic disease, detect acute changes, and decrease the need for hospitalization by providing frequent interaction with health-care providers
visual method patient education material that have a visual component, such as posters, graphics, brochures, handouts, and maps
wellness goal of the health continuum, signifying peak holistic function

Assessments

Review Questions

1. What is the key factor in motivating health-related behavior change according to the Health Belief Model?
   a. perceived susceptibility and consequences
   b. knowledge alone
   c. social pressure
   d. external rewards

2. What is the primary purpose of Healthy People 2030?

a. to provide health-care coverage for all
b. to set goals for health promotion and wellness
c. to address immediate health-care needs
d. to focus on individual medical treatments

3. What principle emphasizes the importance of involving patients in the planning, delivery, and evaluation of their care?
a. holism
b. equity
c. intersectionality
d. empowerment

4. What are the four basic components of a well-balanced physical exercise routine?
a. strength, cardiovascular activity, meditation, flexibility
b. flexibility, muscle strength, cardiorespiratory endurance, postural stability
c. weightlifting, running, yoga, aerobics
d. cardio, weight training, Pilates, mental stability

5. What is the nurse's role in promoting lifestyle changes, and how are lifestyle health–promotion activities categorized?
a. The nurse is an authority figure, and activities are categorized based on age.
b. The nurse is a coach, and activities are categorized as physical or mental.
c. The nurse is a passive observer, and activities are not categorized.
d. The nurse is a researcher, and activities are categorized alphabetically.

6. What is a reason why being part of a community has a positive effect on holistic health?
a. Communities have strict rules that individuals must follow.
b. Being part of a community is irrelevant to individual health.
c. Communities provide resources and relationships that promote optimal health.
d. Community involvement only affects mental health, not physical health.

7. What is the primary focus when promoting health among middle-aged adults, considering the most common causes of death for this age group?
a. mental well-being
b. muscular strength
c. disease prevention and lifestyle modifications
d. social engagement

8. What is the leading cause of death in the young adult age group?
a. cardiovascular disease
b. cancer
c. accidental injury
d. diabetes

9. What age group is often referred to as the "sandwich generation"?
a. young adults
b. middle-aged adults
c. older adults
d. adolescents

10. What is the primary purpose of health education?
a. to increase health-care costs
b. to decrease patient satisfaction

c. to empower individuals to make informed choices
d. to limit patient access to medications

11. What is an example of a task that would empower a patient to prevent readmissions to the hospital?
a. providing entertainment options
b. suggesting new hobbies
c. educating on medication management and potential complications
d. discussing unrelated health topics

12. What is health literacy?
a. the ability to read medical textbooks
b. the level of knowledge an individual has about health care
c. the ability to perform medical procedures
d. the understanding of medical jargon

13. What method of patient education is most suitable for individuals with visual impairments?
a. reading brochures and handouts
b. watching educational videos
c. listening to audio recordings
d. exploring the MyChart feature of the patient portal

14. What patient education method is best suited for teaching practical skills such as wound dressing changes?
a. visual methods
b. audio methods
c. kinesthetic methods
d. technological methods

Check Your Understanding Questions

1. Describe Betty Neuman's health continuum and how nurses can use it to guide interventions at different points on the continuum.

2. How does a positive health concept contribute to individuals' acceptance of health promotion and teaching? Provide examples.

3. Discuss the importance of considering social determinants of health in health-promotion planning.

4. Explain the significance of a consistent sleep hygiene routine and provide examples of nonpharmacological sleep aids.

5. What are the key principles for promoting healthy eating habits, and why is it important to encourage small, manageable changes?

6. Describe the role of mindfulness in promoting holistic health and well-being.

7. Describe two health-promotion topics relevant to older adults and explain why they are important for maintaining their independence and well-being.

8. Identify one modifiable risk factor for disease that is prevalent among middle-aged adults and explain its significance in health promotion.

9. Explain the importance of health education in empowering individuals to obtain their optimal level of health.

10. Describe the role of nurses in health teaching.

11. Describe the significance of preparing and implementing an education plan in patient teaching.

12. Discuss the advantages and drawbacks of technology-focused patient education, considering factors such as access and internet literacy.

13. Explain the importance of providing patient education in the patient's primary language and discuss strategies for overcoming language barriers in health-care settings.

Reflection Questions

1. How can nurses address health-care disparities and promote health equity in their practice?
2. Reflect on the role of spirituality in promoting holistic health. How might understanding and supporting the spiritual aspects of diverse communities contribute to effective health-promotion strategies?
3. Reflect on how societal attitudes toward health promotion might differ among young adults, middle-aged adults, and older adults. How might these attitudes influence the effectiveness of health-promotion initiatives targeted at each age group?
4. Consider the concept of "modifiable risk factors" discussed in the context of middle-aged adults. Reflect on how individuals' awareness and management of these factors might evolve as they transition through different life stages.
5. Consider the concept of health literacy discussed in the content. How might you adjust your communication approach when interacting with a patient with low health literacy levels?
6. Consider the role of nurse navigators and care coordinators in patient education. How do these roles contribute to improving patient outcomes and satisfaction?
7. Reflect on the importance of using external resources for patient education. How can health-care professionals leverage resources from health-care associations to enhance patient understanding and engagement?
8. Reflect on the significance of evaluating patient learning in the patient education process.
9. Consider the impact of technology on patient education. How can nurses address disparities in access to technology and internet literacy among patients?

What Should the Nurse Do?

Selena is a 35-year-old female who works full-time as a marketing executive. Her lifestyle is busy, and she often works overtime. Selena has been feeling fatigued and stressed. Concerned about her health, she schedules a visit with her primary care provider.

Nursing Assessment: Selena reports feeling tired, stressed, and overwhelmed by her schedule. She reports irregular sleep patterns, lack of exercise, and a fast-food diet. Selena's blood pressure is elevated, and her BMI and other measurements indicate that she is overweight.

The nurse must come up with a health-promotion plan for Selena.

1. Selena's lack of exercise is a physical wellness issue. What health-promotion topics would help Selena improve her physical wellness?
2. Stating that she is overwhelmed and stressed indicates that Selena has a mental and emotional wellness imbalance. What health-promotion topics are appropriate to improve Selena's mental and emotional wellness?
3. Patient partnership is key to health-promotion planning. What important contributions can Selena make to the health-promotion plan to individualize it to her value set and personal preferences?

Jorge is a 45-year-old male who has attempted to make lifestyle changes in the past but has faced difficulties sustaining them. He is frustrated by his previous failures and is hesitant to try again. Jorge has a sedentary lifestyle and poor eating habits, and he struggles with work-life balance.

4. How would you as a nurse approach Jorge to understand the reasons behind his previous failures in making lifestyle changes? Outline key strategies to assess his barriers and concerns.
5. Develop a new plan for Jorge that addresses his past challenges and increases the likelihood of sustainable lifestyle changes. Provide two tailored recommendations with rationales.

6. Sarah is a registered nurse working in a community health-care center. Her role involves providing health promotion and education to individuals across different age groups. Recently, she has encountered a challenging situation where she needs to differentiate her teaching approach for young adults, middle-aged adults, and older adults.

   Sarah's first patient of the day is Tom, a 23-year-old college student. Tom is experiencing symptoms of stress and anxiety due to upcoming exams and adjusting to living away from home for the first time. Sarah knows that young adults like Tom often face challenges specifically related to education, financial pressures, and mental health.

   Next, Sarah meets with Lisa, a 45-year-old mother of two who is struggling to balance her career, family responsibilities, and caring for her aging parents. Lisa expresses concerns about her hectic lifestyle and its impact on her health. Sarah recognizes that middle-aged adults like Lisa often face challenges related to managing multiple roles and coping with stress.

   Last, Sarah meets with Mr. Johnson, a 70-year-old retiree who is struggling with mobility issues and chronic health conditions. Mr. Johnson expresses concerns about his increasing dependence on others and fears of losing his independence. Sarah understands that older adults like Mr. Johnson often face challenges related to aging, health literacy, and maintaining independence.

   How can Sarah tailor her education strategies to address the specific concerns of young adults, middle-aged adults, and older adults and effectively promote health and well-being across the life span?

Jamal, a registered nurse working in a busy hospital, is assigned to care for Mr. Sun, a 62-year-old male from China who speaks little English. He is admitted for exacerbation of heart failure. Mr. Sun has a history of heart disease and hypertension. During Jamal's initial assessment, he realizes that Mr. Sun has limited knowledge about his condition and the medications he is prescribed. Additionally, he observes that Mr. Sun seems overwhelmed and anxious about his health.

Jamal faces a dilemma in balancing the need to provide comprehensive health education to Mr. Sun while navigating various barriers that may hinder effective communication and understanding. He recognizes the importance of empowering Mr. Sun to manage his condition effectively to improve his quality of life and prevent readmission.

7. What level of health literacy does Mr. Sun exhibit?
8. What are some cultural or language barriers that could affect Mr. Sun's learning?
9. What are some resources that Jamal could provide for Mr. Sun?

Mariah is a nurse working in a community health center. She encounters diverse patients with varied learning needs daily. By tailoring her approach to accommodate the unique learning needs of each patient, Mariah can ensure that all individuals receive comprehensive education and support to effectively manage their health conditions and improve their overall well-being. How can Mariah address the learning needs of the following four patients?

10. Emma is a 45-year-old female who recently underwent surgery for glaucoma and is now visually impaired. She visits the health center for diabetes management education.
11. Jack is a 60-year-old male who recently suffered a stroke, leaving him with partial paralysis in his right arm and leg. He relies on public transportation because he cannot drive and seeks education on stroke rehabilitation.
12. Adam is a 30-year-old male with dyslexia who struggles with reading comprehension. He visits the health center for education on managing his asthma.
13. Mia is a 55-year-old female who is deaf and communicates primarily through American Sign Language (ASL). She visits the health center for education on heart disease prevention.

Competency-Based Assessments

1. Use the template to create a health-promotion plan for Selena, a 35-year-old female who works full-time as a marketing executive. Her lifestyle is busy, and she often works overtime. Selena reports feeling tired, stressed, and overwhelmed by her schedule. She reports irregular sleep patterns, lack of exercise, and a fast-food diet. Selena's blood pressure is elevated, and her BMI and other measurements indicate that she is overweight.

Health-Promotion Aspect	Individualized Health-Promotion Activity
Physical wellness	
Mental/emotional wellness	
Social wellness	
Spiritual wellness	
Recommended resources	

2. Perform a literature search about a specific type of recent infections in your area, such influenza, COVID-19, or H1N1. Determine how it employs mechanisms to evade the body's immune response. Develop a brief educational presentation for community members to help reduce the risk of infection.
3. Create an engaging handout for patients regarding the importance of obtaining annual influenza and COVID vaccines.
4. Maria is a 65-year-old female who recently underwent knee replacement surgery. She is eager to learn how to properly perform postoperative exercises and manage her pain at home. What are the best methods of patient education to effectively communicate with this patient?
5. Ahmed is a 40-year-old male who was diagnosed with diabetes. He is struggling to understand how to monitor his blood sugar levels and make appropriate dietary changes. What are the best methods of patient education to effectively communicate with this patient?
6. Ella is a 25-year-old college student who has been experiencing symptoms of anxiety. She is interested in learning relaxation techniques and coping strategies to manage her stress. What are the best methods of patient education to effectively communicate with this patient?
7. Javier is a 55-year-old Spanish-speaking male who recently had a heart attack. He has limited English proficiency and requires education on his medication regimen and lifestyle modifications. What are the best methods of patient education to effectively communicate with this patient?
8. Linda is a visually impaired 70-year-old female who needs education on managing her hypertension and taking her medications correctly. What are the best methods of patient education to effectively communicate with this patient?

CHAPTER 4

Clinical Judgment in the Nursing Process

FIGURE 4.1 Health-care providers collaborate to ensure quality patient care. (credit: "Collaborating in the ER: Reservists assist, learn in community hospitals" by Senior Airman Jonathan Stefanko/US Air Force, Public Domain)

CHAPTER OUTLINE

INTRODUCTION Picture this: You are a newly graduated nurse fresh off orientation in a critical care unit. You get reports on two of your patients: one who is on a ventilator after a head injury, and the other who is being treated for heart failure. The nurse giving you the report mentions that the patient with heart failure has been receiving a large dose of diuretic medications and has been having some irregular heartbeats on the monitor. Reflecting on your nursing knowledge, you remember that abnormal potassium levels can affect the heart's rhythm, so you pull up the patient's chart to check. As you suspected, the patient's potassium level is very low, likely from the high dose of diuretics being administered—certain diuretics cause a loss of potassium. You quickly get in contact with the treating provider to recommend potassium replacement to get the patient's levels back to normal.

Had you not made this connection, the patient could have experienced cardiac arrest or other life-threatening symptoms related to their low potassium level. You used your nursing knowledge to make a clinical judgment call that most likely saved your patient's life. The ability to critically think and exhibit clinical judgment in practice are imperative skills for new nurses to have. This chapter explores the shift in nursing practice and education that is currently taking place to put more emphasis on clinical judgment to better prepare new graduates for situations like this.

4.1 Critical Thinking and the Nursing Process

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the purpose of the nursing process
- Define and apply the steps of the nursing process to patient care
- Explain how clinical judgment is used to guide patient care using the nursing process

The steps of the nursing process provide direction for nurses when making patient care decisions (Figure 4.2). Each decision affects the patient's health status, and safe and effective decisions by nurses enhance patient outcomes (Nibbelink & Brewer, 2018). The thought process that allows nurses to arrive at a conclusion based on objective and subjective information about a patient—and thereby achieve positive patient outcomes—is called clinical judgment. This thought process is an essential part of safe and effective decision-making in nursing practice (Tanner, 2006). This chapter focuses on how to use clinical judgment when providing nursing care for medical-surgical patients.

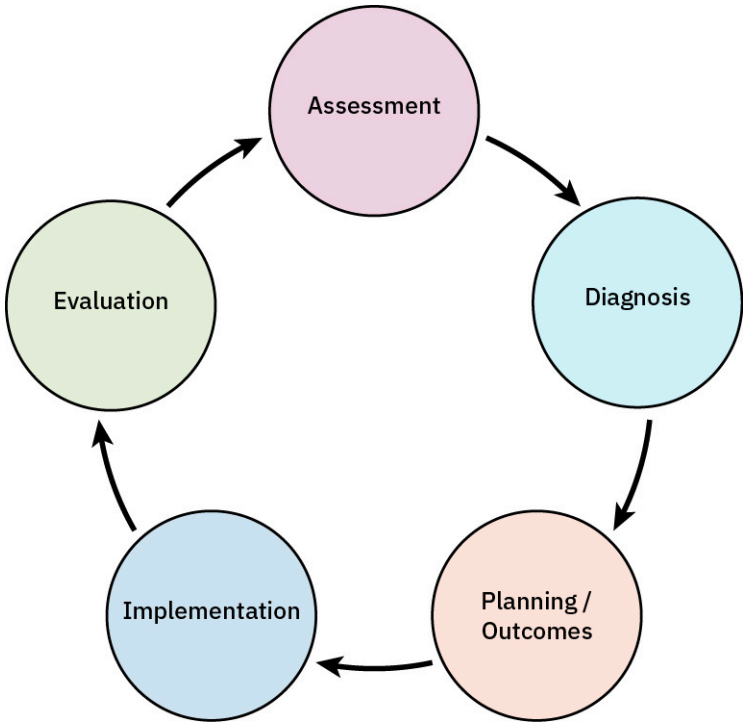

FIGURE 4.2 The nursing process consists of five steps. The nurse usually follows the cyclic direction of the steps but may need to move forward or back based on the patient's responses. (credit: modification of work from *Maternal-Newborn Nursing*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The Nursing Process

The nursing process represents how nurses think. Nurses assess patients to discover subjective and objective patient data. The analysis of the data leads the nurse to diagnose a patient's problems. It is important to note that nursing diagnoses differ from medical diagnoses: they are broader and holistic, encompassing aspects of physical health in addition to psychosocial, cultural, and environmental factors that affect the patient's health. A nursing diagnosis is not the actual medical condition but rather the problems related to the medical condition. The diagnosis leads to the identification of patient outcomes (goals). The nurse begins to develop a plan of care based on prioritizing the identified problems and desired outcomes. The nurse then implements actions to treat the problems, prevent complications, and improve the patient's overall health status. The patient's condition is then evaluated by the nurse to determine if the actions brought about the expected patient outcomes and achieved care goals. The nursing process consists of five steps: assessment, diagnosis, planning, implementation, and evaluation (also known as ADPIE), each of which is discussed in more detail in the following sections.

Assessment

When providing nursing care, assessment includes gathering data from the patient, the patient's medical record, the

patient's family members or caregivers, and physical assessment findings. Assessment also involves analyzing relevant data within the context of the patient's current situation (Benner et al., 2009). This analysis enables the nurse to discover the essential data necessary for making patient care decisions. The nurse acknowledges the expected data, focuses on unexpected findings, and looks for patterns in the data to assist with the formation of a nursing diagnosis and an individualized plan of care. An example is when the nurse notices that over the past three cardiology clinic visits, there has been a gradual rise in the patient's blood pressure measurements to above normal values. The blood pressure pattern is recognized as a trend and is not routine or expected in a healthy patient.

Diagnosis

The analysis of data provides direction for the nurse to identify or determine the patient's current or potential problem(s) and develop a problem-based nursing diagnosis. The nurse also considers the patient's specific situation. Continuing the example from the previous section, based on the assessment data, the patient receives a medical diagnosis of hypertension; some potential problem-based nursing diagnoses would be decreased cardiac output, risk for impaired cerebral tissue perfusion, and activity intolerance. Notice that the nursing diagnoses are broader and encompass problems the patient is experiencing; they do not simply name the condition with which the patient is diagnosed. During this step, the nurse also prioritizes the patient's diagnosed problems. If the same patient arrived in the emergency department with a chief complaint of 10/10 chest pain, the patient's potential myocardial infarction (heart attack) takes priority over treating the patient's underlying hypertension. In this example, the context of the patient's situation has changed. Prioritization of the established diagnoses is the foundation of the patient's plan of care, which leads to the next step in the nursing process: planning.

Planning

For each diagnosis, the nurse identifies outcomes and goals that will enhance the patient's condition and health status. For example, consider the patient with previously diagnosed hypertension who presents to the emergency department with 10/10 chest pain: the planned outcome is opening the blocked vessel to limit cardiac tissue damage. To achieve the intended outcome, the nurse observes and monitors for changes in objective data such as patient vital signs, cardiac rhythm, and physical symptoms such as chest pain and nausea, and reports abnormal findings to the provider. Everyone involved with the patient's care is made aware of the planned actions to achieve the outcomes and provide optimal and targeted patient care.

Implementation

To achieve the prioritized outcomes, the nurse implements a series of planned actions, or nursing interventions. These actions are based on the planned patient outcomes. In the previous example, the actions are planned around the goal of preventing complications from the heart attack. The nursing actions are also prioritized to enhance patient safety and the effectiveness of the treatment and interventions.

Evaluation

Once the nursing interventions have been implemented, the nurse evaluates the patient's current health status to determine if the actions were effective and if the patient outcomes were achieved. This evaluation may result in modifications of the diagnosis, plan, or nursing actions, and reflects the circular nature of the nursing process (see Figure 4.2). The nursing process continues to cycle as the plan of care is modified appropriately (American Nurses Association, 2021). For example, if a patient's pain is not relieved by the prescribed pain medication, the nurse must return to the plan and modify it with additional interventions, such as advocating for a change in the medication order or providing nonpharmacological methods of pain control, such as position change, distraction, or application of ice.

Benefits of Using the Nursing Process in Practice

Using the nursing process has many benefits for nurses, patients, and other members of the health-care team. Using the nursing process

- promotes quality patient care;
- decreases omissions and duplications;
- provides a guide for all staff involved to provide consistent and responsive care;
- encourages collaborative management of a patient's health-care problems;
- improves patient safety;
- improves patient satisfaction;

- identifies a patient's goals and strategies to attain them;
- increases the likelihood of achieving positive patient outcomes;
- saves time, energy, and frustration by creating a care plan or path to follow; and
- improves continuity of care between various providers and institutions.

Clinical Judgment in Nursing

Historically, nursing was often viewed as a task-oriented career, meaning that nurses took orders from physicians without question and carried out nursing tasks. These tasks were usually simple, such as changing bed linens, helping patients use the toilet, and providing hygiene care. However, the profession of nursing has evolved into a more complex and autonomous career over the last several decades. As a valuable part of the health-care team, nurses now use critical thinking skills and clinical judgment in everyday practice to achieve positive patient outcomes. Many times, nurses are the ones tasked with making clinical decisions that will significantly affect the lives of their patients because they are often the first to notice changes and recognize potential problems. For example, a medical-surgical nurse notices that a patient develops facial droop and dysarthria and cannot move their arm. Based on these findings, the nurse decides to make the patient NPO (*nil per us*, which means "nothing by mouth") as a safety precaution to prevent aspiration. The nurse will also perform a neurological assessment and notify the stroke emergency responders according to their institution's policy.

In recent years, nursing education has also evolved to better train nurses to think critically and use clinical judgment in practice. The **Clinical Judgment Measurement Model (CJMM)** was developed by the National Council of State Boards of Nursing (NCSBN) to allow nurse educators to teach, assess, and measure the development of clinical judgment skills in nursing students and new graduates taking the National Council Licensure Examination (NCLEX-RN). The Next Generation NCLEX-RN (NGN) provides a better way to assess the clinical judgment and the decision-making abilities of nursing school graduates. This helps identify nurses who are prepared for contemporary practice, which requires nurses—even newly licensed ones—to make increasingly complex care decisions (National Council of State Boards of Nursing, 2024). The CJMM helps nursing students connect knowledge learned in the classroom to effective clinical care in practice. This model serves as the foundation for nursing critical thinking and skill development and is discussed in more detail throughout the rest of this chapter.

4.2 Clinical Judgment Measurement Model Overview

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the purpose for development of the Clinical Judgment Measurement Model (CJMM)
- Understand how to apply the CJMM to the nursing practice

Researchers at the National Council of State Boards of Nursing (NCSBN) developed the NCSBN Clinical Judgment Measurement Model (CJMM) as a framework for the valid measurement of clinical judgment and decision-making within the context of a standardized, high-stakes examination. Although clinical judgment and decision-making have been important elements in most prelicensure education programs for many years, significant research and development were required to isolate and measure these traits with psychometric rigor. This model is used as a teaching tool within nursing school curriculums and as a guiding framework for the development of new types of questions on the national board exam (NCLEX) to examine the clinical judgment and critical thinking skills of nursing students. By using the CJMM, nurse educators can be confident that they are preparing nursing students to enter practice with high-level critical thinking skills and the ability to make sound clinical judgments when caring for their patients.

LINK TO LEARNING

You can learn more about the NCLEX examination (https://openstax.org/r/77newNCLEXexam) that incorporates concepts from the CJMM and get prepared for test day.

The Clinical Judgment Measurement Model

Though the traditional ADPIE nursing process has existed for a long time and still provides great value to nursing,

many nursing schools are now utilizing the CJMM more, as it further expands on the nursing process and allows it to be broken down into more measurable components.

LINK TO LEARNING

The National Council of State Boards of Nursing created the Clinical Judgment Measurement Model (CJMM) (https://openstax.org/r/77CJMM) to explore new ways of testing clinical judgment in nursing as part of the National Council Licensure Examination (NCLEX). The diagram at this site shows the layers of the model.

Application of the CJMM to Nursing Practice

There are several layers to the CJMM framework. Layer 0 at the top is the broadest layer, encompassing all the clinical decisions that a nurse makes to address a patient's needs—essentially the entire nursing process. However, as you move down the model, you can see that this process is broken into more specific steps that nurses can use to make clinical decisions and address patient needs. As nurses move through layers 2 through 4, they are working through a specific cognitive process that helps them make clinical decisions for patients, using clinical judgment to do so (as represented by the broad layers 0 and 1 at the top of the model). The more specific layers (2 through 4) are discussed in more detail in the following sections.

Form, Refine, and Evaluate Hypotheses

Layer 2 is composed of three different parts: form hypotheses, refine hypotheses, and evaluation. The nurse uses specific patient assessment findings ("cues"), to develop hypotheses about the patient's condition. The nurse uses the cues in combination with their foundational clinical knowledge to determine potential explanations for the patient's situation. As the nurse assesses more cues and obtains more information about the patient, the nurse can refine their initial hypothesis and determine its accuracy. As the nurse moves through the steps in layers 3 and 4 to make clinical decisions, they are also checking in with the parts of layer 2 to continuously reevaluate the plan of care. As you will read in the next section, each of the cognitive skills in layer 3 corresponds to a component of layer 2. As the nurse assesses and cares for a patient, they can determine whether their actions have satisfied the goals of care. If the goals are "not met," the nurse can move again through the steps in layers 3 and 4 to revise the care plan and make different clinical decisions that will hopefully assist in better meeting the patient's needs.

For example, a nurse is caring for a patient who presents with a cough and fever. The nurse assesses the patient and determines that the patient also has a runny nose, shortness of breath, and dyspnea on exertion. The nurse hypothesizes that the patient has a respiratory virus and administers an influenza and COVID-19 test per the provider's order. The COVID-19 test comes back positive, confirming the nurse's hypothesis, so the nurse notifies the provider and initiates appropriate measures as ordered, including supplemental oxygen and intravenous (IV) fluids. The nurse reevaluates the patient several hours later and determines that the patient's symptoms have improved. This is an example of how a nurse could move through the steps of the CJMM to make clinical decisions to address the patient's current needs.

Application of Cognitive Skills

Layer 3 of the CJMM is composed of six steps that involve a repetitious process that improves with time and nursing experience. Eventually, these steps become second nature to a more experienced nurse, but they serve as a framework for nursing students and early-career nurses to use as a more deliberate guide for making clinical decisions. These six cognitive skill steps (also known as clinical judgment functions) are described in more detail in Table 4.1 and throughout the rest of the chapter.

Cognitive Skill	Description
Recognize cues	• Assessment data are collected; this can be subjective (from the patient or family) or objective (from physical assessment performed by the nurse). • Data can also be collected from the electronic health record. • Nurse uses these bits of assessment data and looks for "cues" that may be indicative of what is going on with the patient. • Nurse tries to determine what information is relevant, what is the most important, and whether anything is of immediate concern.
Analyze cues	• Nurse takes the assessment data collected from the previous step and considers how they relate to the patient's history and current situation. • Nurse considers whether the cues collected in the previous step are consistent with the patient's current condition, if any of the cues are immediately concerning, and if there are any additional data that need to be collected. • Nurse attempts to link recognized cues to the patient's clinical presentation and establish probable patient needs, concerns, or problems.
Prioritize hypotheses	• Nurse examines all possibilities for the patient's situation based on collected cues. • Nurse determines which possibilities are most likely, which are most serious, and which are the highest priority to treat first. • Priorities of care are established based on the patient's current health problems and cues assessed in the first two steps.
Generate solutions	• Using hypotheses for the patient's condition from the previous step, nurse plans specific actions to achieve goals and outcomes. • Actions can be classified as "indicated," "contraindicated," or "nonessential" to help determine priority actions. • During this step, the nurse should identify outcomes that are expected with each nursing action and plan care that addresses patient's current needs.
Take action	• Nurse performs interventions; these may include further assessment, monitoring, or teaching, depending on the patient's needs. • Actions are based on nursing knowledge, priorities of care, and planned outcomes to achieve optimal health outcomes for the patient.
Evaluate outcomes	• Nurse reviews patient response to actions and interventions. • Nurse compares observed outcomes with expected outcomes to determine if the plan of care needs to be revised.

TABLE 4.1 Cognitive Skills in the CJMM

The CJMM is more advanced than the traditional ADPIE nursing process for several reasons. First, the focus of the CJMM is critical thinking and clinical judgment. Using this model, the nurse must continuously reassess, adapt, and refine their clinical judgment to make appropriate decisions as new information becomes available or the patient's condition changes. Additionally, the CJMM is more patient-centered; it tailors nursing care by incorporating contextual factors such as the patient's unique preferences, values, and culture, as well as social determinants of health. It is important to recognize that in a time-sensitive situation, clinical judgment might lean toward quick decision-making, whereas critical thinking may advocate for a more deliberate analysis. Navigating conflicts involves balancing the urgency of the situation with the need for a thoughtful approach, ensuring that both critical thinking

and clinical judgment contribute to optimal patient care.

Expected Responses and Behaviors

For each cognitive skill, there are specific responses and behaviors that the nursing student is expected to exhibit. When expected responses are performed by the student, it indicates that the cognitive skill has been adequately demonstrated and the student is using clinical judgment effectively.

- Expected responses and behaviors by the student that would indicate they are able to successfully recognize cues include recognizing assessment data that are pertinent to the patient's condition, identifying subtle changes in the patient's condition, and using knowledge and experience to thoroughly assess the patient.
- For analyzing cues, it is expected that the student can recognize abnormal assessment findings, anticipate patient needs, identify potential complications that may arise, and begin to prioritize patient problems.
- When prioritizing hypotheses, the student nurse should be able to organize data and findings based on patterns and trends and prioritize the patient's goals and needs.
- During the generate solutions (planning) step, the student nurse is expected to collaborate with the interprofessional care team to establish goals of care, prioritize nursing interventions based on the patient's needs, and continuously modify the plan of care based on changes to the patient's condition.
- When the student begins to take action, it is expected that they will accurately perform nursing interventions based on previously established patient priorities and needs, document care appropriately, and provide education to the patient and family.
- When evaluating outcomes, expected behaviors include reassessing the patient's condition to determine whether goals and outcomes have been met, evaluating how effective nursing interventions were, and modifying patient goals and priorities as needed.

Consideration of Factors

It is important to use clinical judgment to make practice decisions within the context of environmental and individual factors, which form layer 4 of the CJMM. These factors help the nurse make informed, personalized decisions. The contextual factors surrounding a nurse's ability to provide care, such as time pressure, prior experience, and task complexity, must be taken into account.

Environmental

External environmental factors are physical and social factors within the external environment that may affect the clinical decision-making process. These include the following:

- setting (e.g., hospital, long-term care, community health center)
- situational factors, such as safety considerations, available equipment, and surroundings
- patient demographics
- resources, such as supplies, staffing, and open beds
- individual medical information, including medical history, lab and diagnostic test results, intake/output, medications, and current treatments
- time pressure related to emergent orders and changes in patient condition
- culture (e.g., diet, religion, language, literacy)
- payment for health-care services

In addition to external environmental factors, there are also many internal environmental factors to consider. These include physiological, psychological, sociocultural, and spiritual factors that influence the patient from within.

CULTURAL CONTEXT

Cultural Context within the CJMM

Cultural factors must be considered as part of the clinical judgment process. Without this context, it may be difficult to ascertain the cause of the patient's condition. For example, in some cultures, a vegetarian diet is commonplace. In the context of this factor, the nurse must consider that a lack of protein and vitamin B_{12} may be the cause of certain medical issues within this population. Although considering cultural factors is important, it is even more important not to generalize information about cultures, as this can perpetuate stereotypes. There is a difference

between generalizing information about all members of a population and asking questions about the patient's culture to get specific information that can help the nurse make informed clinical decisions.

Individual

Individual factors that need to be considered during the clinical judgment process are factors related to the nurse. These factors include the following:

- nurse specialty, knowledge, and skills
- nurse characteristics, including attitudes, prior experiences, and amount of nursing experience
- cognitive load of the nurse (e.g., demands, job stress, problem-solving skills, memory)

REAL RN STORIES

Nurse: Gabby, BSN
Years in Practice: Three
Clinical Setting: Medical-surgical unit
Geographic Location: Small community hospital in rural Georgia

After clocking in for my shift, I was notified by the charge nurse that I would be floating to a different unit for the night. She told me that I would need to go to the labor and delivery unit to help out because there were several patients being admitted who were expected to deliver babies that night. I had only ever worked on a medical-surgical unit, so I expressed that I was concerned and uncomfortable taking care of this patient population. The charge nurse shrugged and told me to get going.

Once I got to the unit, the labor and delivery charge nurse told me I would be taking care of a patient who had just delivered a baby girl. I again expressed my discomfort, as I have never taken care of a new mother or a baby. The charge nurse seemed surprised by this and stated, "I was told they were sending down a nurse with OB experience. Let me make a quick call."

When the charge nurse came back from making her phone call, she informed me that there had been a mistake and a different nurse with OB experience was supposed to float to the unit, not me. I breathed a huge sigh of relief and headed back to my home unit, thankful that I had advocated for the patients and myself.

Throughout nursing school, we kept hearing about "clinical judgment" and making informed care decisions for our patients. I feel like I finally get it now. Even though I wasn't using my clinical judgment to make specific decisions for a patient, I used it to determine that I was not the most appropriate nurse for that assignment. And because I used my clinical judgment skills, I truly believe that patients in both the medical-surgical unit and the labor and delivery unit received higher quality care during that shift.

4.3 Recognizing and Analyzing Cues

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe how to recognize cues found in patient data
- Describe how to analyze the meaning of the relevant cues found in patient data

Recognizing cues is the portion of the CJMM that most closely reflects the assessment part of the nursing process. In the realm of nursing, **assessment**—the systematic and dynamic process of collecting and analyzing data about a client's health—forms the cornerstone of patient care (American Nurses Association, n.d.). The essence of a nursing assessment lies in its comprehensive approach to understanding a patient's health status. At its core, this process aims to identify the needs and concerns of patients, serving as the foundation for subsequent nursing care plans. A nursing assessment is not merely an evaluation of physical symptoms; it encompasses a broader analysis that includes physiological, psychological, sociocultural, and environmental factors influencing a patient's well-being.

In every assessment, nurses are tasked with deciphering a complex array of information. They must sift through various data points, from clinical signs and laboratory results to the patient's expressed concerns and behaviors to

analyze the cues. This process requires not only technical knowledge and expertise but also a keen sense of empathy and intuition. The goal is to create a holistic picture of the patient's health, enabling nurses to prioritize care and interventions effectively.

Recognizing Cues

The primary focus of a nursing assessment is to systematically identify a patient's health concerns. This process involves a detailed examination of the patient's current health status to identify any changes or risks that could affect care and treatment. By determining the urgency of different health issues, nurses can plan appropriate interventions.

To conduct an effective assessment, the nurse must be adept at recognizing a variety of cues: not only the signs of obvious physical health issues, such as high blood pressure or mottled skin, but also subtler indicators that might suggest underlying problems. For example, a patient might mention specific sources of stress or allude to a family history of a particular condition. Keep in mind that assessment is an ongoing, dynamic process; the nurse is continually gathering assessment data to monitor for changes in the patient's condition.

Imagine a patient, Mr. Silva, who has recently undergone knee replacement surgery. The care team, including the nurse, has developed a plan of care to address Mr. Silva's postsurgical needs. While the nurse is performing an assessment three days after surgery, they notice that Mr. Silva's incision is red and warm to the touch. The nurse recognizes that these cues are abnormal and require further investigation and follow-up.

LINK TO LEARNING

A checklist is a useful tool for ensuring the nurse conducts a comprehensive physical examination. This sample checklist (https://openstax.org/r/77checklist) provided by Nightingale College details the steps in a typical head-to-toe assessment.

Subjective and Objective Data Collection

The initial assessment serves as an opportunity to begin compiling a complete set of information about the patient. This database is the cornerstone for all subsequent nursing care and interventions. It includes detailed information about the patient's physical, psychological, and emotional status and forms the basis for developing an individualized care plan.

The process of creating a patient database involves gathering both subjective and objective data. The patient's own descriptions of their symptoms, feelings, and perceptions, as well as relevant descriptions from friends or family members, are known as **subjective data**. The measurable and observable information collected during a physical examination, such as blood pressure, heart sounds, lung sounds, and lab results, is called **objective data** (Lukey, 2023).

In addition to health-related information, a comprehensive database also includes an assessment of the patient's social and environmental factors. This encompasses family health history, social relationships, cultural background, and environmental factors such as living conditions and occupational hazards. These elements play a crucial role in understanding the broader context of the patient's health and wellness.

CULTURAL CONTEXT

Cultural Diversity and the Collection of Data

Understanding and respecting cultural diversity is essential in nursing assessments. Nurses often encounter patients from various cultural backgrounds, and recognizing how cultural factors influence health beliefs and practices is crucial for collecting accurate data. The following examples illustrate the importance of cultural awareness for the care of each individual patient (U.S. Department of Health and Human Services, n.d.):

- Communication styles: In some cultures, direct eye contact might be considered disrespectful, whereas in

others it is a sign of honesty and engagement. Some patients may avoid direct eye contact with health-care providers as a sign of respect, which should not be misinterpreted as disinterest or noncompliance.
- Pain expression: Cultural norms can influence how patients express pain. Some cultures encourage vocal expressions of pain, whereas others may value stoicism. Nurses must realize that a patient who does not outwardly seem to be in pain might nevertheless be hurting.
- Family involvement: In many cultures, family plays a central role in health-care decisions. Family members, including extended family, may participate actively in care discussions and decision-making. Understanding the family dynamics of each individual patient is important for communicating effectively and obtaining accurate health histories.
- Health beliefs and practices: Traditional health practices and beliefs can significantly influence a patient's approach to illness and treatment. Patients may use traditional healing practices alongside or in place of conventional medicine. Being open to these practices and discussing them respectfully can enhance trust and rapport.
- Dietary considerations: Dietary habits rooted in cultural practices can affect health and treatment plans. Certain religious practices, such as fasting during Ramadan for observant Muslims or dietary restrictions for many people who practice Hinduism, can affect medication schedules and nutritional needs.

By incorporating cultural awareness into the data collection process, nurses can ensure they are gathering complete and accurate information while also respecting each patient's cultural background. This approach contributes to more holistic and patient-centered assessments, a crucial component of quality health care.

Analyzing Cues

Analyzing the data collected during a nursing assessment is a critical step in the nursing process. It involves interpreting the gathered information to make informed decisions about patient care. This analytical process requires nurses to identify significant clues, make inferences, recognize patterns, and apply both inductive and deductive reasoning. These skills enable nurses to translate assessment data into actionable insights, forming the basis for accurate nursing diagnoses and effective care plans.

Thinking back to the example about Mr. Silva, the nurse begins to analyze the recognized cues. The nurse notes that the incision site is red and warm to the touch, which is worrisome in the context of having just had knee surgery three days ago. The nurse infers that these findings are related to the surgical procedure and understands that they will require further intervention.

Filtering Through the Data

After data collection, it is necessary to prioritize findings. Nurses are often faced with complex situations and multiple health issues that need timely attention. They must quickly identify which needs are most critical and must be addressed first to ensure patient safety and well-being. This approach is particularly vital in emergency settings or with patients having multiple chronic conditions of varying immediacy and severity. Prioritizing ensures that the most urgent conditions are treated promptly while still addressing other important health needs in a systematic manner. Even for routine assessments, it is important to prioritize, as not every piece of data is relevant to a patient's care. Some of the most effective methods for filtering through the data to prioritize care include using the ABCs (airway, breathing, circulation) and Maslow's hierarchy of needs. Once the priority patient issues have been established, the nurse can move on and begin analysis of the assessed cues.

LINK TO LEARNING

Learn more about Maslow's hierarchy of needs (https://openstax.org/r/77Maslow) in this article, which includes a figure of the hierarchy.

Clues and Inferences

Identifying clues involves recognizing significant pieces of information in the assessment data. For example, if a patient reports increased shortness of breath and the nurse observes swelling in the legs, these clues might suggest heart failure. A conclusion drawn from clues is called an **inference**. In this case, the nurse might infer that the

patient's heart failure is worsening. Making accurate inferences based on observed clues is crucial for identifying a patient's health issues and planning appropriate interventions.

Recognizing Patterns and Trends

Recognizing patterns and trends in the assessment data is another key aspect of cue analysis. Patterns can indicate the progression of a disease, effectiveness of a treatment, or development of complications. For instance, a pattern of increasing blood pressure readings over several visits might indicate poorly controlled hypertension. Recognizing these patterns helps nurses anticipate and prevent complications, adjust treatments, and advocate for changes in the care plan.

Inductive Reasoning

Noticing cues, making generalizations, and creating hypotheses are all part of **inductive reasoning**. Cues are data that fall outside of expected findings that give the nurse a hint or indication of a patient's potential problem or condition. The nurse organizes these cues into patterns and creates a generalization. A **generalization** is a judgment formed from a set of facts, cues, and observations; the act of generalizing is like gathering pieces of a jigsaw puzzle into patterns until the whole picture becomes clearer. For example, if a nurse observes that a patient's wound is not healing despite standard care, and similar cases have shown improvement with a different treatment approach, the nurse might conclude that an alternative treatment might be beneficial for this patient. Based on generalizations created from patterns of data, the nurse creates a **hypothesis**, or a proposed explanation for a situation, regarding a patient problem, which is the next step in the CJMM and discussed in more detail in the following section.

Deductive Reasoning

Another method for analyzing cues, **deductive reasoning**, is referred to as "top-down thinking." Deductive reasoning relies on using a general standard or rule to create a strategy. Nurses use standards set by their state's Nurse Practice Act, federal regulations, the American Nursing Association, professional organizations, and their employer to make decisions about patient care and to solve problems.

Think about this example: Based on research findings, hospital leaders determine patients recover more quickly if they receive adequate rest. The hospital creates a policy for quiet zones at night by initiating no overhead paging, promoting low-speaking voices by staff, and reducing lighting in the hallways. Nurses further implement this policy by organizing care for patients that promotes periods of uninterrupted rest at night. This is an example of deductive thinking because the intervention is applied to all patients regardless of whether they have difficulty sleeping.

REAL RN STORIES

Nurse: Maria, RN, BSN
Years in Practice: Twelve
Clinical Setting: Endocrinology unit
Geographic Location: San Antonio, Texas

As a nurse in the endocrinology unit, I encounter many patients with complex cases of diabetes. One such case that stands out involved a patient, Mr. Hernandez, who was admitted with poorly controlled type 2 diabetes and recurrent foot ulcers.

From the initial assessment, it was clear that Mr. Hernandez's situation was multifaceted. He reported being diligent with his medication, yet his blood glucose levels were consistently high. Through careful observation, I noticed his reluctance to discuss dietary habits and a general lack of knowledge about diabetes management. This was my first clue that there might be more to his condition than medication adherence.

Using my communication skills, I gently probed into his daily routine and eating habits. This revealed a pattern of sporadic mealtimes and consumption of high-carbohydrate foods, despite his medication regimen. It became evident that Mr. Hernandez's understanding of diabetes management was limited, affecting his ability to control his condition effectively.

Applying inductive reasoning, I hypothesized that a lack of education about diabetes and inadequate nutritional guidance were contributing to Mr. Hernandez's poor health outcomes. This was further supported by the pattern of

his uncontrolled blood glucose readings in relation to his eating habits.

Using deductive reasoning, based on the general principles of diabetes management, I concluded that comprehensive patient education was crucial. I worked with the diabetes education team to develop a tailored education plan for Mr. Hernandez, focusing on nutrition, medication management, and foot care.

The integration of in-depth assessment, inductive and deductive reasoning, and a focus on patient education led to significant improvements in Mr. Hernandez's condition. His experience is a testament to the effect of holistic nursing care and the importance of collecting and analyzing a wide range of data when managing complex health conditions.

4.4 Prioritizing Hypotheses, Generating Solutions, and Taking Action

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the development and prioritization of nursing hypotheses
- Explain how the nurse generates solutions to address patient needs and achieve care goals
- Identify appropriate nursing actions based on specific patient situations

After assessing and analyzing cues, the nurse proceeds to the next steps in the CJMM, which are prioritizing hypotheses and generating solutions. The nurse uses the specific patient assessment findings (cues), in combination with their foundational clinical knowledge, to develop hypotheses, or educated guesses, about the patient's condition. As more cues are assessed and more information about the patient is obtained, the nurse can refine their initial hypothesis, determine its accuracy, and generate specific solutions and interventions for the patient.

Once the solutions and interventions are determined, the nurse can take action. Taking action involves implementing appropriate nursing interventions in an effort to achieve desired patient outcomes. The nurse uses a combination of clinical judgment and critical thinking skills to determine which nursing interventions are the priority actions and implements them accordingly.

Prioritizing Hypotheses

A hypothesis is a proposed explanation for a situation. It attempts to explain the "why" behind the problem that is occurring. If a "why" is identified, then a solution can begin to be explored. No one can draw conclusions without first noticing and then prioritizing cues. Paying close attention to the patient, environment, and interactions with family members is critical for inductive reasoning. As you work to improve your inductive reasoning, begin by first noticing details about the things around you. Be mindful of your five primary senses: the things you hear, feel, smell, taste, and see. Nurses need strong inductive reasoning patterns to be able to take appropriate action quickly, especially in emergency situations.

Remember the example involving Mr. Silva, who recently underwent knee replacement surgery. After assessing him, the nurse finds the surgical incision site is red, warm, and tender to the touch. The nurse recognizes these cues as signs of infection and then develops a hypothesis that the incision has become infected. The nurse also notices that an order has been placed to transition Mr. Silva from NPO status to a regular diet, which involves informing the patient and may involve contacting the dietary services department. The nurse prioritizes the incision findings because, left untreated, the infection could become more severe and eventually life-threatening. The provider is notified of the patient's change in condition, and a new prescription is received for an antibiotic. After the antibiotics have been ordered, the nurse moves onto changing Mr. Silva's diet. This is an example of prioritizing hypotheses in nursing practice.

Generating Solutions

Based on prioritized hypotheses, nurses must use clinical judgment and knowledge to determine both actual problems that the patient is currently experiencing and potential problems that the patient may experience in the future. This involves looking at the comprehensive patient history and significant findings and thinking of the best and worst possible outcomes. The best outcome indicates progress toward recovery. In contrast, the worst outcome will reveal patient deterioration and decompensation. The nurse must always be thinking two steps ahead. Most people do this type of thinking in everyday life and probably do not even realize it. Think back to the last time you

took a road trip. Did you just hit the open roads without any thought to the destination or plan to get there? Successful travelers put some serious planning into the trip to ensure the best possible outcome. The same example can be related to nursing practice. Before initiating interventions, the nurse must first establish specific patient goals (outcomes).

Thinking back to the example about Mr. Silva, the nurse decides that the provider should be made aware of the abnormal incision site findings. The nurse alerts the provider and anticipates that the provider will order antibiotics. The nurse also determines that it would be beneficial to change the patient's dressing to ensure that the site is left clean, dry, and intact to prevent worsening infection.

Outcomes or Goals

A desired result or goal after implementation of the patient's individualized plan of care is called an **outcome**. Identified outcomes may be long-term goals or short-term goals, but they should always follow the SMART goal format (Figure 4.3). The nurse considers five factors related to outcome identification:

- specific measurements to determine success of outcomes
- measurability of desired outcomes
- attainability of the outcome based on outlined timeline and available resources
- relevance of the outcomes for the specific patient with their unique qualities and need
- timeline that is appropriate for the desired outcomes

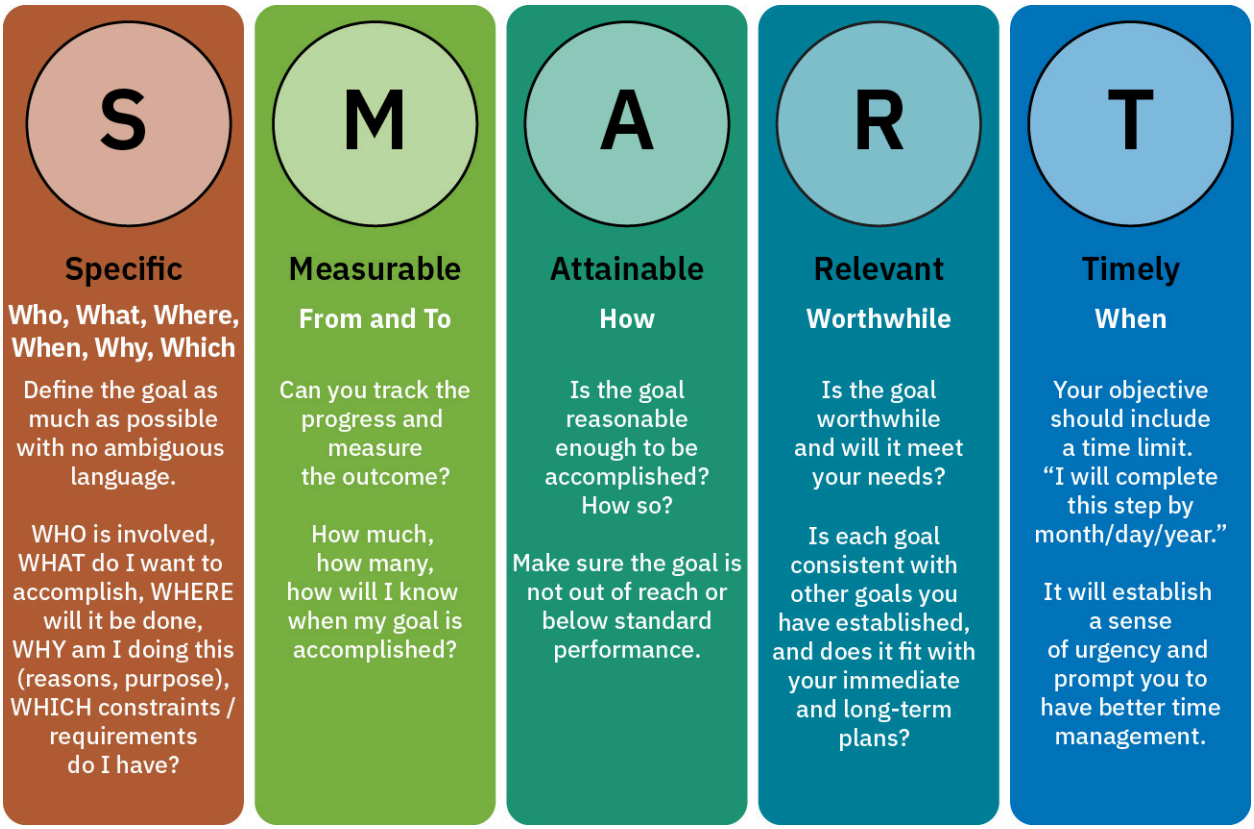

FIGURE 4.3 Patient goals should be specific, measurable, attainable, relevant, and timely (SMART). (credit: modification of work from *Fundamentals of Nursing*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Realistic Outcomes

The nurse will determine if the outcome identified is realistic, meaning reasonable and attainable for this specific patient. For example, patients who experience minor surgical procedures typically begin to move very soon after surgery and possibly walk within a day of (or even the same day as) the procedure. However, this is not realistic for all patients. Think about a patient who has been prescribed physical therapy to gain muscle coordination and strength training after surgery. After one session of therapy, it is realistic and attainable to expect the patient to walk a few steps in the room with assistance. It is not realistic or attainable to expect that the patient will walk 500 ft (150 m) to the nurse's station and back without assistance. Although common sense can help with outcome

identification, a strong use of critical thinking is also warranted.

Expected Time Frame for Completion

Just as with any goal or expectation, a time frame for completion must be set. Having a set time frame enables the nurse to implement the interventions and, at the end of the period, evaluate the interventions' effectiveness. The nurse and health-care team should collaborate to set the time frame with the patient's input when possible. There are two types of outcome identification regarding time frames: short-term and long-term.

Short-Term Goals

A **short-term goal** has a time frame of days to a week; some are even within the assigned shift. Most short-term goals are intended to be achieved before the patient is discharged. This allows the health-care team to evaluate the effectiveness of a newly prescribed treatment, medication, or specific intervention. For example, a patient with an indwelling Foley catheter may have identified the following goal or outcome: "The patient will void (urinate) within two hours after removal of the Foley catheter." This outcome allows the health-care team to ensure the patient regains bladder function. Another example of a short-term goal is for a patient who has been recently diagnosed with diabetes. This patient might identify the following outcome: "The patient will demonstrate how to check their own blood sugar using the return demonstration method before discharge." Achieving this goal ensures the patient will be able to self-monitor their blood sugar upon discharge.

Long-Term Goals

A **long-term goal** generally has a time frame that lasts longer than a few days: it can be several weeks or even months. Long-term goals often involve ongoing activities or interventions, long after the patient has been discharged. Examples of long-term goals include wound care; medication protocols; and cardiac, respiratory, or physical rehabilitation. Long-term goals often are set to improve quality of life.

Generating Solutions to Achieve Goals

In the CJMM, generating solutions serves as a pivotal stage in the nursing process. This is where nurses translate their prioritized hypotheses into actionable interventions aimed at achieving patient-centered goals and outcomes. In combination with an understanding of the patient's health status, the nurse uses their clinical expertise and evidence-based practice guidelines to formulate tailored solutions. While generating solutions, the nurse must consider the physiological, psychological, sociocultural, and environmental factors influencing the patient's well-being, ensuring that interventions are not only clinically effective but also aligned with the patient's values, preferences, and individualized care needs. Whether administering pharmacological treatments, implementing therapeutic interventions, or facilitating health promotion strategies, nurses can use a variety of interventions to address patient care goals. As the nurse moves through the steps of the CJMM to make clinical decisions, they are also continuously checking in to reevaluate the plan of care. As the nurse assesses and cares for a patient, they can determine whether their actions have satisfied the goals of care.

Taking Action

Thinking back to Mr. Silva, the care team, including the nurse, has developed a plan of care to address Mr. Silva's postsurgical needs. This plan includes interventions for pain management, mobilization exercises to regain knee function, and wound care to prevent infection. The team is confident that the plan can achieve Mr. Silva's desired outcomes, which include effective pain control, improved mobility, and wound healing without complications (Cleveland Clinic, 2023).

However, the team also knows that simply having a plan is not enough; it needs to be implemented effectively in a patient-centered way. The implementation phase in nursing includes several key areas of emphasis: actively putting the plan into action and gauging the patient's response to the interventions. For example, in this stage of the CJMM, the nurse would implement specific actions to address the incision site findings, such as administering antibiotics as prescribed and changing the dressing.

Patient-Specific Interventions

For Mr. Silva, putting the plan into action begins with the nurse administering prescribed pain medication; this intervention should help to manage postoperative pain and facilitate early mobilization. The nurse also coordinates with the physical therapy team to initiate mobilization exercises and ensure the exercises align with Mr. Silva's pain management plan. This interprofessional coordination is crucial to balance pain control with the need for early

movement to prevent complications such as blood clots or stiffness in the knee.

In addition to these interventions, the nurse plays a pivotal role in wound care. This includes regularly changing dressings, monitoring the surgical site for signs of infection, and educating Mr. Silva on how to care for his wound. Effective implementation also requires all members of the health-care team to continuously evaluate the effectiveness of each intervention. Health care is a dynamic process, and Mr. Silva's evolving needs and responses should guide the implementation of his care plan. This same sentiment can be applied to care for all patients, regardless of their condition or the care setting. All interventions should be tailored specifically to the patient, ensuring that the care provided is optimized for the patient's needs and goals.

Gauging Patient Response

Gauging the patient's response to interventions is a critical aspect of the implementation, or taking action, phase. It involves observing and interpreting how the patient reacts to the care plan, both physically and emotionally. This process is essential for ensuring that interventions are effective and align with the patient's needs and comfort levels. Nurses assess responses through various means, including direct feedback from the patient, clinical observations, and monitoring vital signs or other relevant health indicators. This ongoing assessment allows the nurse to make timely adjustments to the care plan, ensuring it remains responsive and patient-centered.

In Mr. Silva's case, the nurse would closely monitor his responses to pain medication and physiotherapy. This might include observing changes in his pain levels, mobility, and overall comfort during and after mobilization exercises. If Mr. Silva reports increased pain or discomfort, the care team may need to reassess the approach to pain management or the intensity of the exercises. Similarly, the nurse would observe the healing of Mr. Silva's surgical wound, being alert to any signs of infection or poor healing so the team can make necessary adjustments to the wound care regimen. This careful monitoring ensures that Mr. Silva's recovery stays on track and that any concerns are addressed promptly.

REAL RN STORIES

Nurse: Emily, RN, BSN
Years in Practice: Five
Clinical Setting: Outpatient ophthalmology surgical center
Geographic Location: Seattle, Washington

As a nurse in an ophthalmology surgical center, I've seen a variety of postoperative cases, but one patient, Mr. Henderson, taught me the importance of swift adaptation during the implementation phase. Mr. Henderson, a 68-year-old retiree, had just undergone cataract surgery. Initially, his recovery seemed textbook-perfect: he was alert and his initial vision checks were promising. However, during a routine check the morning after his surgery, I noticed he was unusually quiet and seemed hesitant to open his operated eye.

After I gently inquired, Mr. Henderson admitted to experiencing "a bit of discomfort" in his eye, which he initially thought was normal after surgery. But as I further assessed his condition, it became clear that his discomfort was more than typical postoperative irritation. His eye was slightly redder and more swollen than expected, and he reported a sensation of "pressure" in his eye.

Recognizing these as potential signs of postoperative complications, possibly an infection or increased intraocular pressure, I immediately informed the ophthalmologist. We adjusted Mr. Henderson's care plan, increasing the frequency of eye drops to manage potential inflammation and scheduling an urgent follow-up examination.

The quick response was crucial. The ophthalmologist confirmed the early signs of infection and adjusted Mr. Henderson's medication accordingly. This intervention prevented what could have escalated into a severe complication, potentially jeopardizing his vision recovery.

This experience reinforced for me how critical it is to gauge patient responses meticulously during the implementation phase. Even seemingly minor complaints or changes in condition can be indicative of significant issues. It's a reminder that as nurses, our vigilance and ability to adapt care plans can have a profound effect on patient outcomes.

4.5 Evaluating Outcomes

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Evaluate nursing actions to determine if they were effective in achieving patient outcomes
- Describe how to modify nursing plans of care to more effectively achieve optimal patient outcomes

Imagine you have set a goal for yourself: to run a marathon. It is a challenging objective, requiring not just determination but also a strategic plan. Your plan will likely include a detailed training schedule, a balanced diet, and regular health checkups to monitor your fitness levels. However, creating this plan is just the beginning. The next crucial step is implementation: putting your plan into action. This means adhering to your training schedule, running regularly, gradually increasing your distance, eating according to your diet plan, and consistently monitoring your health. Each of these actions is a step toward your goal, bringing you closer to being marathon-ready.

Yet, the process does not end with implementation. The final phase is possibly even more important. Despite your best efforts, suppose that on the day of the marathon you are unable to complete the 26.2 mi (42.2 km). This is where you need to evaluate your plan by analyzing what went wrong and identifying areas for improvement. Did you train sufficiently? Were there nutritional gaps in your diet? Did you give your body enough time to recover between training sessions? Addressing these questions will help you understand the shortcomings of your initial plan and make necessary adjustments for your next attempt.

This process of planning, implementing, and evaluating is not just relevant for personal goals such as running a marathon. It is also a fundamental approach in various fields, including nursing. Nurses plan and implement care plans and then evaluate outcomes, ensuring that patient care is continuously improved and adapted to achieve the best possible outcomes.

Evaluating Outcomes

The systematic determination of a patient's progress toward the achievement of outcomes and goals set during the care-planning process is called **evaluation**. Looking at the CJMM, the evaluation phase follows the phase of taking action, marking the final step. Evaluation is a dynamic and ongoing activity in which nurses assess whether the patient's health status is improving, staying the same, or perhaps worsening in response to the nursing interventions. This phase is crucial as it determines the effectiveness of the nursing care provided, informs necessary changes to the care plan, and ensures that the patient's health needs are being met adequately (American Nurses Association, n.d.).

Let us revisit Mr. Silva, whose case we have been following throughout the implementation phase following his knee replacement surgery. The nursing team has diligently executed the planned interventions for Mr. Silva's postoperative care, including managing his pain, assisting with mobility exercises, and educating him about his condition. As we enter the evaluation phase, it is time to critically assess the outcomes of these interventions. Did they improve Mr. Silva's condition as expected? Are there any aspects of the care that need adjusting? This module will guide us through the systematic approach to evaluating Mr. Silva's progress, employing the essential tools and criteria nurses use to analyze and measure the effectiveness of the care provided (Cleveland Clinic, 2023).

Determine Patient Progress

In the evaluation phase, determining the patient's progress is a fundamental step. For Mr. Silva, who has been recovering from knee surgery, this involves a comprehensive review of his current health status compared to the expected outcomes outlined in his care plan. The nursing team assesses various factors, such as the reduction in pain levels, improvement in mobility, and adherence to postoperative instructions. This step is crucial as it provides an insight into the effectiveness of the interventions and whether Mr. Silva is on track with his recovery. This step is not only about noting improvements but also identifying any areas where progress might be lagging or any complications that may have arisen.

Analyze Current Data

Nurses are continually obtaining and analyzing data from their patients, and the evaluation phase is no different (Lukey, 2023). To analyze Mr. Silva's current data, the nursing team reviews his medical records since the start of the implementation phase, including vital signs, pain assessment scores, and progress in physical therapy sessions.

These objective data provide measurable, observable evidence of Mr. Silva's recovery progress. For instance, a decrease in pain scores and an increase in the range of motion in his knee indicate positive responses to pain management strategies and physiotherapy.

Furthermore, the team considers subjective data, such as Mr. Silva's own reports of pain and his feelings about the progress he is making. This type of information is crucial as it provides a holistic view of the patient's experience and recovery. The team also evaluates the effectiveness of patient education by assessing Mr. Silva's understanding of and adherence to postoperative care instructions, such as medication schedules and exercise routines. This comprehensive analysis helps the nursing team make informed decisions about any necessary adjustments to the care plan, ensuring it remains aligned with Mr. Silva's health needs and recovery goals.

Modifying Nursing Care Plans

After determining patient progress and analyzing current data, the nursing team should have a good idea about whether patient goals were met. This information is essential for guiding the next steps in patient care, whether the team continues with successful strategies or reevaluates and modifies the care plan to address challenges. This modification is based on the conclusions drawn from the evaluation data and can take several forms, depending on the patient's progress and current needs. For Mr. Silva, who is recovering from knee surgery, the nursing team faces decisions on whether to continue, revise, or terminate certain aspects of his care plan, depending on his recovery status and response to the interventions.

If the nursing team concludes that Mr. Silva is progressing well and meeting the recovery goals as expected, the decision may be to continue with the current plan. For instance, if Mr. Silva's pain levels are well-managed and he is showing steady improvement in mobility, the existing pain management strategies and physical therapy exercises would be continued. Continuing a care plan is appropriate when the patient is responding positively to the interventions and the goals are being progressively met.

Should the evaluation reveal that Mr. Silva's recovery is not progressing as anticipated, or if he encounters new challenges, the nursing team may decide to revise the care plan. This could involve altering his pain management regimen if his pain is not adequately controlled or introducing different physical therapy techniques if his mobility is not improving as expected. Revising a care plan is necessary when the current interventions are not fully effective or when the patient's condition changes.

REAL RN STORIES

Nurse: Junot, RN, BSN
Years in Practice: Six
Clinical Setting: Community health clinic
Geographic Location: San Diego, California

In my six years as a registered nurse, particularly in a community health setting, I've learned the importance of being adaptable and responsive when it comes to patient care plans. A memorable case that highlights this was with Mr. Jacobs, a 52-year-old patient with a diagnosis of high cholesterol.

Initially, we had developed a care plan focusing on lifestyle modifications: diet changes, increased physical activity, and regular health monitoring. Despite our efforts, Mr. Jacobs's cholesterol levels remained high during subsequent checkups. This was a clear indication that our initial plan was not as effective as we had hoped.

Acknowledging this, we revised Mr. Jacobs's care plan. We introduced a more structured diet program and added a cholesterol-lowering medication. We also involved a dietitian for more personalized dietary guidance and scheduled more frequent follow-ups to closely monitor his progress.

The revised plan showed significant improvement in Mr. Jacobs's cholesterol levels. He became more engaged in his care, often sharing his new recipes and exercise routines with us. His dedication and our collaborative approach paid off, and over time, his cholesterol levels stabilized to a point where we could gradually reduce and eventually terminate the medication.

This experience with Mr. Jacobs reinforced for me the dynamic nature of nursing care. It highlighted the necessity of continually evaluating and adjusting our care plans, staying patient-centric in our approach, and being open to changing strategies when initial plans don't yield the expected results. The success of this case was a testament to the power of collaboration, patient involvement, and the willingness to adapt for the betterment of patient health.

Summary

4.1 Critical Thinking and the Nursing Process

- The nursing process is a five-step process that serves as the foundation of nursing practice.
- The nursing process consists of assessment, diagnosis, planning, implementation, and evaluation.
- The nursing process typically moves in a forward direction, but at times the nurse must circle back to previous steps to gather more patient data or perform additional interventions.
- This is a continuous process that allows the nurse to provide and evaluate care to promote optimal patient outcomes.
- The Clinical Judgment Measurement Model (CJMM) was developed to help nursing students learn, practice, and demonstrate clinical judgment skills.

4.2 Clinical Judgment Measurement Model Overview

- Historically, nursing was often viewed as a task-oriented career, but in recent years the profession has grown in terms of autonomy and clinical judgment.
- The CJMM, a tool designed to measure critical thinking and clinical judgment in nursing students, was developed to allow educators to assess the development of nursing student's critical thinking skills to help ensure that they are ready to practice as a nurse after graduation.
- The CJMM involves several steps that have expanded upon the traditional nursing process model, making it an excellent framework to guide new nurses in making clinical judgment calls in practice.

4.3 Recognizing and Analyzing Cues

- Nurses use diverse sources and methods to gather critical subjective and objective data during patient assessments.
- Patient data collected by the nurse are analyzed and prioritized based on the patient's specific situation and current needs.
- By prioritizing throughout the nursing process, nurses ensure that immediate, life-threatening conditions are addressed, while also considering each patient's overall well-being and long-term health needs.
- Analyzing the data involves identifying clues and making inferences, recognizing patterns, and applying inductive and deductive reasoning.

4.4 Prioritizing Hypotheses, Generating Solutions, and Taking Action

- After recognizing and analyzing patient cues, the next steps of the CJMM are prioritizing hypotheses, generating solutions, and taking action.
- The nurse uses the cues from the previous steps to develop hypotheses, or educated guesses, about what is causing the patient's health problems.
- The nurse works closely with the patient to develop outcomes, or goals, of care and to generate solutions that aim to achieve those goals.
- Taking action involves implementing appropriate nursing interventions in an effort to achieve desired patient outcomes.

4.5 Evaluating Outcomes

- After implementing interventions, the nurse evaluates their effectiveness to determine whether care goals have been met.
- Based on these findings, the nurse can revise the plan of care and implement different nursing interventions as necessary.
- The evaluation phase technically marks the end of the CJMM cycle; however, CJMM is a continuous process that nurses move through when providing nursing care.

Key Terms

assessment systematic and dynamic process of collecting and analyzing data about a client's health

Clinical Judgment Measurement Model (CJMM) nursing practice and education model that allows nurse educators to teach, assess, and measure the development of clinical judgment skills in nursing students

deductive reasoning type of thinking that involves using a general standard or rule to create a strategy
evaluation systematic determination of a patient's progress toward the achievement of outcomes and goals set during the care-planning process
generalization proposed explanation for a situation
hypothesis judgment formed from a set of facts, cues, and observations
inductive reasoning type of thinking that involves noticing cues, making generalizations, and creating hypotheses
inference conclusion drawn based on collected information
long-term goal outcome that has a time frame of weeks to months
objective data measurable and observable information collected during a physical examination
outcome the desired result or goal after implementation of the patient's individualized plan of care
short-term goal outcome that has a time frame of days to a week
subjective data patient's own descriptions of their symptoms, feelings, and perceptions, as well as relevant information obtained from friends and family members

Assessments

Review Questions

1. Which step of the nursing process involves analyzing patient data within the context of the patient's current situation to discover essential information for making patient care decisions?
   a. diagnosis
   b. assessment
   c. planning
   d. implementation

2. What is the primary purpose of prioritizing problem-based nursing diagnoses in the nursing process?
   a. to identify current health issues and potential complications
   b. to enhance communication among health-care team members
   c. to evaluate care outcomes after interventions have been performed
   d. to address patient concerns and preferences

3. The nurse notices that a patient is experiencing an increased heart rate and blood pressure. Which step of the nursing process is the nurse currently in?
   a. assessment
   b. diagnosis
   c. planning
   d. implementation

4. An emergency department nurse is caring for a patient who presents with a cough and shortness of breath. The nurse asks the patient about their medical history and notes that they have a history of heart failure. The nurse determines that the cough and shortness of breath are likely related to heart failure exacerbation. Which cognitive skill of the CJMM is the nurse exhibiting in this situation?
   a. recognize cues
   b. analyze cues
   c. prioritize hypotheses
   d. take action

5. What is a situation that best illustrates a nursing student generating solutions?
   a. The student takes a blood pressure reading on a patient.
   b. The student checks the patient's chart to look at lab results.
   c. The student determines that the patient's wound is infected and needs a new dressing.
   d. The student performs skin care on the patient's open wound.

6. A nursing student is working within an interdisciplinary care team to establish care goals for a patient. Which step of the CJMM is the nurse using?

a. recognize cues
b. analyze cues
c. generate solutions
d. evaluate outcomes

7. What individual factor should a nurse consider when making clinical judgment calls in practice?
a. care setting
b. resource availability
c. cultural preferences
d. skill level

8. What assessment finding is an example of subjective data?
a. blood pressure
b. skin color
c. patient's stated chief complaint
d. respiratory rate

9. How does cultural diversity influence the collection of data during a nursing assessment?
a. by necessitating the exclusion of certain cultural practices to maintain objectivity
b. by affecting communication styles, pain expression, and dietary considerations
c. by encouraging nurses to rely solely on objective data rather than subjective reports
d. by limiting the types of information that can be collected during the assessment process

10. The nurse is conducting a comprehensive assessment of a 65-year-old patient admitted to the hospital with complaints of chest pain and shortness of breath. The patient has a history of hypertension, diabetes, and smoking. During the assessment, the nurse notices that the patient avoids making direct eye contact and seems hesitant to discuss their symptoms. Which aspect of the nursing assessment is highlighted in this scenario?
a. recognizing cues
b. obtaining objective data
c. documenting patient responses
d. showing cultural competence

11. The emergency department nurse notices that several patients admitted to the unit recently have reported experiencing nausea and vomiting shortly after receiving a specific type of medication. Additionally, these patients exhibit elevated levels of liver enzymes upon laboratory testing. What aspect of cue analysis is most relevant in this scenario?
a. identifying clues
b. making accurate inferences
c. recognizing patterns
d. drawing conclusions from observed data

12. The nurse notices a recurring pattern among patients admitted to the unit who have been prescribed a particular antibiotic for the treatment of infections. Despite following the standard treatment protocol, a subset of patients continues to exhibit persistent symptoms and delayed recovery. Based on this observation, what form of reasoning is the nurse likely to utilize in proposing alternative treatment approaches?
a. inductive reasoning
b. analytical reasoning
c. deductive reasoning
d. abstract reasoning

13. The emergency department nurse is caring for a patient who presents with sudden onset of chest pain, shortness of breath, and diaphoresis. What is an example that illustrates the nurse prioritizing a hypothesis?

a. The nurse applies supplemental oxygen.
b. The nurse suspects the patient is experiencing a myocardial infarction.
c. The nurse takes the patient's vital signs.
d. The nurse administers pain medication to the patient.

14. What is the primary purpose of prioritizing hypotheses in the nursing process?
a. initiate interventions without further analysis
b. determine the patient's preferred treatment options
c. develop a structured plan for care delivery
d. refine decisions for interventions based on the acuity of problems

15. While performing a head-to-toe assessment on a patient in the hospital, the nurse notices that the patient is experiencing sudden confusion and agitation. What is an example of a nursing intervention that most closely reflects the CJMM step of taking action?
a. Recommend the provider order a sedative medication.
b. Ask the patient why they are feeling agitated.
c. Assess the patient's vital signs and oxygen saturation levels.
d. Assume the patient is having a panic attack.

16. The nurse is caring for a patient who presents to the emergency department with worsening shortness of breath and sudden weight gain. The nurse performs a physical assessment and notes edema in the lower extremities and auscultates crackles in the lungs. The nurse anticipates that the patient is experiencing a heart failure exacerbation. Which step of the CJMM is the nurse illustrating?
a. assessing cues
b. prioritizing hypotheses
c. generating solutions
d. taking action

17. The nurse is caring for a patient who reports 6/10 arm pain. After administering acetaminophen, what evaluation finding would indicate that the action was effective?
a. decrease in patient's reported pain level
b. slowdown in urinary output
c. respiratory rate of 20 breaths per minute
d. clear sounds from lungs

18. The nurse is caring for a patient with chronic hypertension who is prescribed lisinopril. Despite taking the medication daily, the patient's hypertension is not improving. The nurse relays this information to the provider and advocates for an increase in the medication dosage. Which aspect of the CJMM does this action by the nurse most closely resemble?
a. assessing cues
b. recognizing cues
c. taking action
d. evaluating outcomes

Check Your Understanding Questions

1. Describe how the nursing process promotes quality patient care and enhances patient outcomes.

2. What is the difference between the ADPIE nursing process and the CJMM?

3. What is the difference between subjective and objective patient data?

4. What is the difference between short- and long-term goals?

5. What are the key components of the evaluation phase in the CJMM and why is this phase crucial in the nursing process?

Reflection Questions

1. Why do you think clinical judgment is an important skill to have as a nurse?
2. How have you used inductive or deductive reasoning when caring for patients in clinical?
3. Why is it important to prioritize hypotheses in nursing practice?
4. Describe a scenario from your nursing practice or clinical experience where you had to make adjustments to a patient's care plan based on your assessment of their progress. How did you determine whether the interventions were effective, and what factors did you consider when deciding on the modifications to the care plan?

What Should the Nurse Do?

Mrs. Johnson, a 65-year-old female patient, presents to the emergency department with complaints of shortness of breath and chest pain. She has a history of hypertension and hyperlipidemia. On examination, Mrs. Johnson appears anxious, with elevated blood pressure (160/90 mm Hg), increased heart rate (110 bpm), and labored breathing. Her oxygen saturation is 88 percent on room air. Mrs. Johnson reports that the shortness of breath and chest pain began suddenly about two hours ago while she was at home. She describes the chest pain as a crushing sensation in the center of her chest that radiates to her left arm. She has not experienced this type of pain before and notes that it is not alleviated by rest.

Further questioning reveals that Mrs. Johnson has a family history of coronary artery disease, with her father experiencing a myocardial infarction in his 60s. She admits to occasionally missing her hypertension medication due to forgetfulness. Additionally, she reports a recent increase in stress due to caring for an ailing spouse.

1. The nurse determines that Mrs. Johnson's medical history of hypertension and hyperlipidemia are related to her current presentation. Which step of the CJMM is the nurse in?
2. The nurse applies supplemental oxygen and performs an electrocardiogram (ECG), per the provider's orders. Which step of the CJMM is the nurse in?

Mr. Lee, a 50-year-old male, arrives at the clinic with complaints of chronic fatigue, unexplained weight loss, and persistent abdominal pain. He has a history of type 2 diabetes and hypertension. On examination, Mr. Lee appears visibly fatigued, with a blood pressure of 140/90 mm Hg, a heart rate of 95 bpm, and a body mass index (BMI) indicating recent weight loss.

As the nursing team delves deeper into Mr. Lee's case, additional information unfolds. Mr. Lee reports that the chronic fatigue has been progressively worsening over the past few months, significantly affecting his daily activities and overall quality of life. His unexplained weight loss, approximately 15 lbs (6.8 kg) over the last three months, has been unintentional and accompanied by a loss of appetite. The persistent abdominal pain, which he describes as a dull ache that intensifies after meals, is localized in the upper abdomen.

Further exploration of Mr. Lee's medical history reveals suboptimal diabetes management, with inconsistent blood glucose monitoring and irregular medication adherence. Additionally, he reports occasional episodes of dizziness and blurry vision, which he attributes to his hypertension medication.

3. Based on the information provided and using the CJMM, what cues should the nurse recognize as potentially being relevant to the patient's condition?
4. Based on the recognized cues, what further information should the nurse gather to analyze the cues?

Competency-Based Assessments

1. Consider a scenario where a patient presents with symptoms that are initially unclear. Prepare a presentation that discusses how a nurse might use the nursing process to navigate the uncertainty and how this would contribute to improved patient outcomes.
2. Create a flowchart indicating how the nursing process contributes to continuity of care for patients transitioning between health-care settings, such as from hospital to home care. Provide specific examples.
3. Write an example of a clinical story showing how a nurse effectively uses all parts of the CJMM to make a

decision that positively affects a patient outcome.

4. With a peer, debate a scenario in which critical thinking and clinical judgment might conflict. How can a nurse navigate such conflicts to ensure the best possible patient care?
5. Develop a SMART goal for a patient with activity intolerance related to heart failure exacerbation.

CHAPTER 5

Ethical Decision Making

FIGURE 5.1 Decisions about ethical dilemmas should always be discussed among all members of the health care team. (credit: "3D Scales of Justice" by Chris Potter/flickr, CC BY 2.0)

CHAPTER OUTLINE

INTRODUCTION In today's complex, modern world, we are surrounded by ethical dilemmas. Ethical dilemmas in nursing practice are as common as they are diverse. In health care, the focus on ethics has intensified in response to the increasing number of controversial developments, such as advances in technology and the ability to prolong life, as well as access to health care and financial resources. This is further complicated by the increase in average life expectancy, resulting in more people seeking health care.

Although many individuals benefit from a better quality of life, some may find themselves in a situation of extended suffering when prolonging life, which often comes at great expense. There are also many ethical issues surrounding the delivery of health care and allocation of health care resources based on one's age, race, gender, disability, and social mores.

Although there may be no clear solutions to these dilemmas, the fundamental philosophical principles are the same. Nurses can use clinical judgement to reason their way through these dilemmas by having an awareness and understanding of underlying philosophical principles. This allows the nurse to provide safe patient care and provide education to patients in an ethical manner. Unique challenges are also created in the profession of nursing. This chapter will discuss the impacts of ethics on nursing care.

5.1 Clinical Judgment and Ethical Dilemmas

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the role of ethics in clinical judgment
- Define common ethical principles
- Analyze common causes of ethical dilemmas in health care
- Describe the process of ethical decision-making

Moral philosophy, or ethics, is the discipline related to what is morally right or wrong and creates a framework that guides decisions related to ethical patient care. Nurses make life and death decisions daily, making ethics the foundation of integrity within the nursing profession. Ethical decision-making ensures the patient's autonomy is respected and equitable and culturally competent care is provided in alignment with a patient's beliefs and values.

The principles outlined in the Nursing Code of Ethics are the foundation that guides nurses to use clinical judgement and provide high-quality, patient-centered care. Historically, the Nursing Code of Ethics is rooted in the Hippocratic Oath, which has guided health care professionals for centuries through the use of a set of principles. In 1950, the American Nurses Association (ANA) developed the modern-day version of the Nursing Code of Ethics that has evolved with the changing needs of patients and nurses.

Clinical Judgement

The process used by nurses when making decisions, called clinical judgment, is a key attribute of professional nursing. It is based on nursing knowledge, critical thinking, and clinical reasoning, which is then used to understand and interpret information related to the delivery of care and how it affects care outcomes. The steps involved in clinical judgement help a nurse gather and analyze data to make ethical decisions. Clinical judgement and the clinical judgement measurement model are discussed in greater detail in the chapter on Professional Medical-Surgical Nursing.

A basic understanding of concepts associated with moral philosophy as well as understanding one's role in ethical decision-making will prepare the nurse not only to articulate their ethical positions but also to develop the needed skills to make ethical decisions in alignment with their clinical judgement.

LINK TO LEARNING

The America Nurses Association (ANA) is an organization that represents the interests of the nation's registered nurses. The ANA fosters high standards within the nursing profession by promoting a safe and ethical work environment, promoting the health and wellness of nurses, and advocating for health-care issues that affect nurses and the public to ultimately improve the quality of health care for all. The ANA Code of Ethics for Nurses with Interpretive Statements (https://openstax.org/r/77ANA) will prepare you for situations that will arise throughout your nursing career.

Although the terms "morals" and "ethics" are often used interchangeably, they are not the same. The definitions of both terms describe beliefs related to right and wrong and suggest guidelines for a potential corrective action, but there are slight differences between the two terms. A person's or society's idea of what is right or wrong, called **morality**, is usually associated with one's behavior. The values or system of values that are considered moral by a community, called ethics, is often culturally based. Ethics focuses on a formal, systematic study of moral beliefs, whereas morality focuses on adherence of informal, personal values (Loggins, 2023).

Ethical Principles

The nursing profession requires a high degree of ethical responsibility. As health care providers, patients not only trust their nurses to make well-informed decisions to ensure quality care and optimal outcomes, but they also rely on nurses to advocate for their best interests. The ANA's Professional Standards includes a framework of principles and guidelines for the nursing profession. Specifically, the ANA Code of Ethics provides a definitive guide to ensure that ethical standards are upheld (ANA, 2015). Ethics includes the principles of autonomy, beneficence, justice, and

nonmaleficence. The core of nursing practice includes concepts such as respect, compassion, and empathy, upon which ethical principles are built. Adherence to ethical principles ensures patients receive the highest quality care while the integrity of the nursing profession is maintained.

Autonomy

The ethical principle of autonomy acknowledges that patients have the right to maintain control and to make their own decisions related to treatment and care (ANA, 2015). Autonomy is also referred to as the right to **self-determination**, meaning patients have the moral and legal right to determine what will be done with and to their person. By providing patients the information they need, informed decisions can be made that align with their values, beliefs, and preferences. This enables the interdisciplinary team to coordinate care in alignment with the patient's wishes as well as promote strong relationships that ensure quality care. For example, this principle would enable the interdisciplinary team to support and respect a patient's decision about the acceptance or refusal of life-sustaining treatments.

Beneficence

The ethical principle of beneficence relates to the nurse's responsibility to act in their patient's best interest; in essence, it is the duty to do good. The ANA defines this principle as "preventing harm, removing harmful conditions, or affirmatively acting to benefit another or others" (ANA, 2015, p. 41), and it emphasizes the promotion of the patient's well-being and interests to improve the patient's health outcomes and overall welfare. Nurses uphold this principle as they prioritize each patient's individual needs while providing compassionate, patient-centered care that includes health promotion and disease prevention strategies. As a nurse, there will be instances, such as noncompliance that results in frequent hospitalizations, that make it difficult to provide compassionate patient-centered care. An example is patients with heart failure; heart failure has the highest 30-day readmission rate, which is mostly due to ineffective self-care (Alnomasy & Harmon Still, 2023). Despite the frustration in these types of situations, the nurse has an ethical duty to provide compassionate care.

Justice

The ethical principle of justice refers to treating all patients fairly and equitably. This principle requires that all individuals, regardless of race, age, sex, sexual orientation, gender identity, ethnicity, or social status, receive quality care with safe outcomes to ensure equitable distribution of health care and resources. Nurses should recognize and address social justice issues as well as advocate for policies and practices that promote health equity. Whereas equality means giving everyone access to the same resources regardless of their own special circumstances, equity takes into account individual challenges and advantages, and means providing assistance necessary to create an equal outcome for all, *considering* their circumstances (Figure 5.2). For example, when free flu vaccines are offered first to all older adults, we are using the ethical principle of justice. It is more equitable to administer the vaccines to older adults first because they are at higher risk.

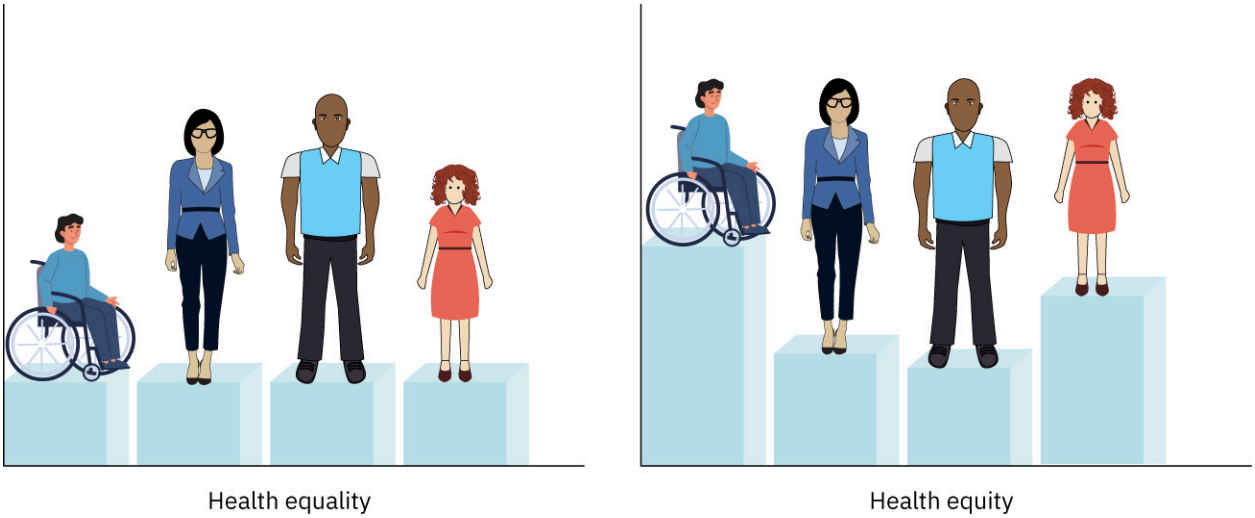

FIGURE 5.2 Equity takes into account individual circumstances and provides necessary assistance to create an equal outcome. (modification of work from *Psychiatric-Mental Health Nursing*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Nonmaleficence

The ethical principle of nonmaleficence refers to the duty to do no harm, which we hear of as part of the Hippocratic Oath for medical doctors. It is also a foundational principle in nursing practice. This principle requires nurses to be vigilant, observant, and proactive while prioritizing potential risks and benefits of treatment options and simultaneously promoting healing, health, and well-being. All of these requirements can be achieved by selecting interventions that will cause the least amount of harm while also achieving the most beneficial outcome. For example, you may be caring for a mentally ill patient who has verbalized homicidal ideations that include a plan to harm someone and then themselves. As the patient's nurse, you may feel torn regarding the patient's privacy and the treatment plan that could divert the homicidal ideations (NCSL, 2022). However, a nurse's duty is to do no harm while also ensuring the patient's and other individuals' safety (Loggins, 2023).

It is important to note that most states have laws in place that either require or permit health-care professionals to disclose information about patients who may become violent (NCSL, 2022). These laws have received increased attention following the increase of mass shootings. Some states, such as New York, have changed the reporting requirements from a permissive to a mandatory duty for health-care professionals to report when they believe a patient may pose a danger to themselves or others. A specific case in California, Tarasoff v. The Regents of the University of California (Laves, 1979), created a passage of "duty to warn" or "duty to protect" laws in almost every state. These laws afford health-care professionals immunity from civil and criminal liability for disclosure of confidential mental health information. The specific requirements vary by state, making it important to consult your risk management department when faced with a duty to warn or protect.

Fidelity

There is also the ethical principle of **fidelity**, which includes a model of care delivery that incorporates altruism, loyalty, caring, and honesty. For example, when an older adult patient with intact cognitive function is diagnosed with a terminal illness but they do not want to share this information with their family, it can create an ethical dilemma. This requires that no health-care information be shared without the patient's consent to maintain the established trust between the patient and nurse. It also requires consultation within the interdisciplinary team members, such as case managers, social workers, and clergy, to identify community resources to provide support and services that the patient may need as their disease progresses.

Causes of Ethical Dilemmas

The human phenomenon of caring is the basis of the nursing profession. Though the nurse wants the best care for their patients, identification of the best care is not always easy; it may be compounded by an ethical dilemma. It is important for the nurse to be aware of major ethical dilemmas that are easily recognized, as well as daily interactions with patients and families that may give rise to ethical challenges that are not always easily recognized. Common topics that can create ethical dilemmas faced by nurses include

- Confidentiality of patient information, especially with the increased use and availability of computers
- End-of-life issues related to pain control, do not resuscitate (DNR) orders, do not intubate (DNI) orders, life support, or food and fluid issues
- Refusing to provide care for reasons ranging from a conflict in personal values to fear of personal risk of injury
- The use of restraints. It is important to weigh the risks of limiting a patient's autonomy against the increased benefits to patient safety.
- Trust issues related to the use of placebos (an inactive substance used in place of the actual medication) when conducting nursing research or situations in which the family and provider have decided it is better to withhold certain information from a patient.

Ethical Decision-Making

It is inevitable that nurses will encounter ethical dilemmas in many challenging patient care situations. Determining the correct action for each situation can be very stressful. Through use of the ethical principles of autonomy, beneficence, nonmaleficence, and justice outlined by the ANA, a solid foundation is provided for ethical decision-making (ANA, 2015). This foundation is a guide to promote a logical, systematic framework for ethical decision-making.

The approach to ethical decision-making can follow the steps in the Clinical Judgement Measurement Model (Table

5.1).

Step	Guidelines to Assist in the Ethical Decision-Making Process
Recognize and analyze cues (Assess the ethical/moral situation)	• Are there any procedural conflicts related directly to the patient or to the primary decision-maker, the family or guardian, or health-care providers? • Be attentive to any legal, ethical/moral, or professional dilemmas. • Collect data about the patient's interpretation of their health, their cultural beliefs, and resources or barriers. • Identify the most important people involved in the dilemma. • Recognize any moral problems in relation to ethical principles or professional obligations.
Prioritize hypotheses and generate solutions (Determine the nature of the dilemma, apply ethical principles, create potential courses of action)	• Address any associated legal data (e.g., DNR orders). • Assess the patient's decision-making capacity. • Include medical facts, diagnoses, and treatment options as well as the values, beliefs, and religious components. • Outline the ethical/moral issues associated with the situation; apply principles of autonomy, beneficence, nonmaleficence, and justice. • Plan possible courses of action.
Take actions (Consider potential consequences of options, list the alternatives)	• Ask "What if...?" or "If, then...?" questions. • Compare and contrast the potential outcomes. • Compare the alternatives with the associated ethical principles, as well as with the nursing code of ethics.
Evaluate outcomes (Decide and evaluate the decision)	• Are there any ethical reasons impeding your decision? If so, what is your response to these ethical reasons? • List the ethical reasoning for the decision. • What is the best or correct course of action?

TABLE 5.1 Use of the Clinical Judgement Measurement Model in Ethical Decision-Making

Hospital ethics committees began to emerge in the early 1980s and, in time, became the primary source for dealing with ethical issues. Described in more detail later in the chapter, ethics committees provide support for health-care professionals when ethical challenges arise during clinical practice and are often consulted by nurses to help guide decision-making when ethical dilemmas are present during health-care delivery (Aulisio, 2016). Ethical dilemmas arise for a host of reasons (Hajibabaee et al., 2016) and can include the following:

- Assignments that are contradictory to personal cultural or religious beliefs or with the Code of Ethics for Nurses
- Complicated decision-making processes in health care
- Considerations associated with advancing medical technology
- Considerations to protect a patient's rights
- Diversified beliefs related to medical involvement
- Diversity of lifestyles
- Diversity of morals, religious values, and cultural beliefs
- Incompetent peers
- Life and death decisions that must be made
- Patients refusing treatment

- Political and legal issues related to patient independence, euthanasia, and assisted dying
- Short-staffing or staff who fail to meet their responsibilities

Avoiding ethical dilemmas is impossible, but equipping yourself with knowledge to face these dilemmas is essential. The most important thing is to deal with each situation in a professional manner that promotes quality care and patient safety.

LINK TO LEARNING

This article from the *Journal of Medical Ethics and history of Medicine* provides an in-depth understanding of ethics committees (https://openstax.org/r/77CodeofEthics) and the ethical challenges faced by health-care providers.

5.2 Patient Care and Safety

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze what it means for nursing to be the most trusted profession
- Discuss how ethical nursing care involves advocacy for patient safety
- Apply HIPAA and maintaining confidentiality to the role of the nurse

For nurses to promote integrity in patient care and safety, it is imperative to be knowledgeable about the ANA's Code of Ethics for Nurses. In addition, nurses must be knowledgeable about the standards of practice for the profession, including relevant federal, state, and local laws and regulations, as well as the employing organization's policies and procedures. When nurses encounter inappropriate or questionable practices or when incompetent, unethical, illegal, or impaired practices are not corrected, nurses should follow the established process for reporting and handling these matters.

When nurses must responsibly report these kinds of situations, the state nurse's associations should be available to provide advice and support for their members to navigate the development and evaluation of the reporting process and procedures. Reporting questionable practices will likely carry a substantial risk to the nurse (e.g., the fear of retaliation or threat to job security); however, the professional organization has a responsibility to protect the practice of nurses who choose to report their concerns. It is important to note this risk does not negate the obligation to report threats to patient safety.

The Most Trusted Profession

Not only is the nursing profession accountable to society but nurses have been named the most trusted profession for the twenty-first year in a row (ANA, 2023). This is because nurses are trusted not only by their patients but also because of the high ethical standards that are implemented during the delivery of patient-centered care. According to a Gallup poll, "nurses continue to garner the highest ethics ratings from Americans among a diverse list of professions, a distinction they have held for more than two decades" (Brenan, 2023, para 1). The ANA President also recognized the 4.4 million nurses in the United States and commended them on their role in maintaining the health and safety of their patients (ANA, 2023).

Ethical Care and Safety

The Code of Ethics for Nurses is the foundation of the nursing profession's promise to provide and advocate for safe, quality care for all patients and communities. Nurses work diligently to preserve patient-centered care and safety while navigating ethical dilemmas. It is of utmost importance that nurses remain alert to situations that present incompetent, unethical, illegal, or impaired practices or actions that could result in harm to a patient. When situations of this nature arise, nurses have a duty to take the appropriate action to resolve such matters. Examples of such situations are listed in Table 5.2.

Situation	Appropriate Action
An incompetent act within the organization that could result in patient harm	• Maintain a focus on the patient's best interests. • The concern should be expressed to the colleague involved in a clear and supportive manner. • Uphold the integrity of the nursing practice.
A colleague who is impaired while on duty	• Consult supervisory personnel. • Extend compassion and caring to the colleague throughout the process of identification, remediation, and recovery. • If appropriate, help the colleague access appropriate resources. • The concern should be expressed to the colleague involved in a clear and supportive manner.
A practice in the health-care delivery system or organization that could compromise a patient's welfare	• Express the concern to the responsible manager or administrator. • When indicated, express the concern to an appropriate higher authority within the organization. • Or, if necessary, express the concern to an appropriate external authority.
An incompetent, unethical, illegal, or impaired practice that is not corrected	• Nurses must report the issue to the appropriate external authorities. • External authorities include practice committees of professional organizations, licensing boards, and regulatory or quality assurance agencies. • Certain situations may warrant the notification of all such groups, including law enforcement.

TABLE 5.2 Unethical Situations and Appropriate Responses

When reporting potentially unethical acts, it is important that factual documentation and accurate data are included in the report. It is the duty of the nurse to protect the patient, the public, and the profession from practices that may result in harm. When responsibly reporting, the professional organizations also have a duty to protect the practice of nurses who choose to report their concerns through formal channels.

Advocacy

Nurses are on the frontline of care delivery and are at the center of patient communication when ethical dilemmas are inevitable. The act of pleading for a cause, idea, or policy, or **advocacy**, is an ethical obligation of all nurses to ensure their patients are protected from harm. Nurse advocacy is one of the most important responsibilities and is crucial to optimizing patient outcomes by:

- Communicating with providers on the patient's behalf
- Helping patients navigate the health-care system (e.g., billing, medical care, insurance, assisting with legal issues)
- Mediating obstacles to quality patient care
- Promoting patient safety
- Protecting against social injustice
- Protecting patients' rights
- Providing patient education
- Providing pertinent information and education to help patients make informed decisions

Patients rely on nurses to be their voice as well as to provide support during their time of need when they are not well and are confronted with uncertainties about their health and care. Nurses shoulder a big responsibility because they are often the first and last point of contact for patients, establishing an integral part of the patient-nurse trust relationship.

Refusing to Provide Care

The ANA Code of Ethics for Nurses indicates that nurses have the same duties to self as to others. This includes preservation of wholeness of character as well as preservation of integrity. There may be times when nurses find themselves in circumstances that exceed their moral limits or that violate their moral standards. When this occurs, nurses should express their concerns to the appropriate authority. Nurses are justified in refusing to participate on moral grounds when a specific decision or action is felt to be morally objectionable, especially when it may result in jeopardy to a patient, family, community, population, or to the nursing practice. Nurses who choose to not to participate on these grounds should do the following:

- Communicate the refusal in time for alternate arrangements to be made for patient care.
- Communicate this decision in a timely, appropriate manner.
- Express refusals in advance.

It is important to note that conscience-based refusals to participate in patient care do not include personal preference, prejudice, bias, convenience, or arbitrariness. Although conscientious objections are based on religions or moral grounds, they may not protect nurses from formal or informal consequences. In fact, refusal to provide care for a patient can be viewed as patient abandonment. Patient abandonment occurs when a health-care professional refuses to treat a patient or is negligent in not being available when a patient needs care. This act is a punishable crime and can result in the loss of the nurse's license.

Although nurses do have a right to refuse to participate in patient care that conflicts with personal religious beliefs, nurses cannot refuse care on the basis of discrimination or dislike. An example of a religious conflict may be refusing to provide abortion care; a discriminatory conflict may be related to providing care for an incarcerated individual or a patient with a substance use disorder. Although it can be quite challenging to care for certain patients if you have a moral objection, nurses have an obligation, a duty, to provide the same level of care to all patients.

Confidentiality and the Health Insurance Portability and Accountability Act

With the increased use of technology and increased access to information, maintaining patient confidentiality (privacy) in the health-care industry has become a daunting task. The Health Insurance Portability and Accountability Act (HIPAA), which became federal law in 1996, created national standards to protect patient privacy and prohibited health information from being disclosed without patient consent or knowledge in almost all situations. HIPAA has two components: the HIPAA Privacy Rule and the HIPAA Security Rule. These rules are designed to protect an individual's health information while also enabling the needed flow of the health information to provide quality care. It is important to note that no health information can be shared with an outside provider without the patient's written consent. Examples of HIPAA violations include speaking a patient's name while in another patient's room and leaving chart documents in public view.

Certain information may be disclosed under defined policies, mandates, or protocols. The written guidelines must ensure the patient's rights, safety, and well-being are protected. This type of information includes for purposes of

- Continuity of care
- Education
- Peer review
- Professional practice evaluation
- Quality improvement
- Risk management
- Third-party payments

Nurses must be vigilant in safeguarding privacy for individuals, families, and communities to maintain the trust developed through the nurse-patient relationship. The expectations are that personal information will not be disclosed without their consent, which is facilitated by nurses and other health-care providers maintaining this level of confidentiality. It is a nurse's duty to maintain confidentiality of all patient information, including personal and

clinical information in the work setting and while off duty. It is especially important that nurses remain diligent when maintaining data security when using electronic communications or working with electronic health records. Additionally, nurses not only advocate for privacy for individual patients, they also participate in creating policy and practices to protect both personal and clinical information throughout entire health-care practices and facilities. It is also important to note that patient information of any kind, including pictures of patients, should not be used on any personal social media sites.

LINK TO LEARNING

From salary to staffing, delegation to documentation, and even cutting-edge topics such as social media, ANA has principles aimed at giving you practical information (https://openstax.org/r/77ANAPrinciples) for your professional practice.

5.3 Ethical Patient Education

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the ethics of providing patient education
- Discuss the benefits of focusing on ethics in patient education

Personal beliefs can affect how nurses approach patient education, especially when a nurse does not believe in or agree with specific treatments or health-care choices. Examples of this may include specific types of treatments or surgeries, medications, or certain vaccines. Despite personal beliefs, nurses have a responsibility to present factual, evidenced-based education to patients that is in alignment with current standards of care and practice. Education should be based on what a treatment does, and not what the nurse believes.

The use of systematic patient education improves the likelihood that patients can meet their specific health-care needs. Despite a patient's willingness to learn, the nurse has a responsibility to present information that will motivate the person to recognize the necessity to learn. Health education is vitally important to nursing care because it promotes the ability of patients and families to behave in ways that are conducive to optimal self-care.

How Nurses Educate Patients

The various learning experiences designed to promote behaviors that facilitate health are considered **health education**. It is essential to promote optimal patient outcomes. The function of teaching in nursing is included in state practice acts and the ANA Code of Ethics for Nurses. Nursing care is directed toward promoting, maintaining, and restoring health; preventing illness; and assisting people to adapt to the residual effects of illness. This mindset should result in making every encounter with a health-care consumer an opportunity for education.

Nurses should provide education that is simple, patient centered and **multimodal** (i.e., using a variety of methods) to ensure the health literacy of patients and caregivers is met. Health literacy, as defined by the Centers for Disease Control and Prevention (CDC), is "the degree to which individuals have the ability to find, understand, and use information to inform health-related decisions and actions" (CDC, 2023b, para 2).

It is also important to be mindful that patients can feel overwhelmed by receiving too much information, making it necessary to keep the process simple. To ensure patient education is easily understood:

- Do not go too in-depth into a disease process with a newly diagnosed patient.
- Provide written information to enable the patient to review it later.
- Provide the patient education in the patient's preferred language, when possible.
- Speak slowly and relay the instructions clearly.
- Use layman terms and visual aids.

To advance patient education:

- Begin patient education with each encounter starting at admission.
- Ask the patient how they would explain their disease (step-by-step teach-back technique).

- Be mindful of the patient's limitations and strengths.
- Determine the patient's learning style.
- Determine what the patient already knows and correct any misinformation.
- Include the family in all patient education as much as possible, using the same suggestions.
- Provide information about signs and symptoms of the patient's condition that may warrant immediate attention.
- Stimulate the patient's interest.
- Take advantage of educational technology.
- Use return demonstration, involving the patient from the very first treatment.

Providing Ethical Education

It is important to maintain an ethical mindset when providing patient education, to ensure the teaching focuses on what a treatment does and not what the nurse believes. Effective health education promotes individual and community wellness and is directly related to positive patient care outcomes. Teaching is an integral tool used by nurses to help patients and families adopt effective health behaviors and alter lifestyle patterns that create a predisposition to health risks. Providing ethical health education includes ensuring the education materials:

- Are accurate and up to date
- Consider the psychosocial situation of the patient
- Include cultural factors, religious beliefs, and values
- Take health disparities into consideration

Providing Education Ethically

To provide education in an ethical manner, the teaching cannot be biased. Just as every patient has a right to equitable patient-centered care, every individual has a right to the same patient education, regardless of age, gender, or socioeconomic status, that is aligned with a patient's beliefs and values.

Ethical development of patient education includes but is not limited to:

- Being mindful of cultural and religious differences
- Being mindful of the patient's communication barriers, especially sensory impairment such as sight or hearing, as well as cognitive disabilities
- Considering the health disparities of each patient
- Providing continuous, compassionate education, especially for patients who have a limited understanding of how behavior affects health
- Providing educational content in a variety of forms to capture patients' different learning styles
- Providing educational materials in the patient's native language with their health literacy in mind
- Writing down important information so the patient can take it after discharge

The preventable differences that underserved populations experience related to disease, injury, or violence that can negatively impact health are considered **health disparities** (CDC, 2023a). Health disparities result from multiple factors, which include poverty, environmental threats, inadequate access to health care, individual and behavioral factors, and educational inequalities. Nurses should be sure that any educational material is developed with the patient's health disparities in mind.

Benefits of Ethical Patient Education

Patient education that considers health disparities, health equity, cultural and religious differences, and health literacy is a win-win for the patient and the health-care team. Benefits of ethical patient education include

- Changing communities with each health consumer encounter
- Creating a stronger patient-nurse trust relationship
- Decreasing re-hospitalizations
- Helping patients manage their health more effectively to improve outcomes
- Improving health literacy
- Increasing the patient's ability to understand how behavior choices affect health
- Meeting consumers' expectations for comprehensive health information
- Motivating the patient's desire to learn

- Providing motivation to choose a healthier lifestyle
- Reducing health disparities while improving health equity

REAL RN STORIES

Nurse: Carolyn
Years in Practice: 15
Clinical Setting: Hospital

Carolyn, a nurse who has maintained the practice of compassionate care during her 15 years of nursing, practices mindfulness related to each patient's different learning styles. Carolyn is vigilant in providing educational material that is appropriate for each patient's learning style, which helps increase the amount of information the patient can absorb and use in their decision making.

Mr. Smith is a 70-year-old patient with congestive heart failure and chronic obstructive pulmonary disease who is preparing for discharge. Carolyn observed during the course of his hospitalization that Mr. Smith is a visual learner as well as a kinesthetic/tactile learner. To address Mr. Smith's visual style of learning, Carolyn teaches Mr. Smith disease management techniques daily so he can see and observe the techniques and decisions Carolyn uses in the daily in-patient care. Carolyn also provides written instructions, pictures, and diagrams for Mr. Smith to reference once he is home.

Carolyn sees that Mr. Smith learns best when he is physically engaged during the learning process. The physical engagement helps distract Mr. Smith from his difficulty sitting still, allowing him to learn through hands-on demonstrations and teaching. To address Mr. Smith's kinesthetic/tactile learning style, Carolyn walks Mr. Smith through using his metered-dose inhaler, setting up his continuous positive airway pressure (CPAP) machine, and administering breathing treatments. Carolyn and Mr. Smith work well together with the hands-on education and return demonstrations, or "teach-back" what they have learned.

Carolyn also has a second patient ready for discharge. Ms. Johnson is a 65-year-old patient with insulin-dependent diabetes. Carolyn observes that Ms. Johnson is an auditory learner as well as a reading and writing type of learner. Carolyn is mindful to talk through her daily routines and care during her time with Ms. Johnson, knowing Ms. Johnson will retain more beneficial information to ensure an optimal long-term outcome after discharge. Carolyn reinforces medication information by saying it out loud each time she administers Ms. Johnson's insulin to ensure Ms. Johnson will recall how to use her new insulin pen. Closer to the patient's discharge date, Carolyn begins having Ms. Johnson use return demonstrations that help reinforce her dietary and medication needs as well as lifestyle choices.

With Ms. Johnson also being a reading and writing type of learner, Carolyn helps Ms. Johnson write down the important information. The process of writing and reading the instructions reinforces the educational materials for Ms. Johnson and will also serve as a reference upon her return home.

Carolyn loves being a nurse and helping people. Carolyn's efforts to ensure her patients are equipped with the education to meet their needs have established trust, provided peace of mind for her patients and families, and will ensure better outcomes for the patients upon their arrival home. Taking time to help patients understand and manage their disease equips them to make healthier lifestyle choices to promote better outcomes. This is an important part of the foundation of how and why nurses have become the most trusted profession in the United States.

5.4 Ethical Challenges in Scope of Practice

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the Code of Ethics in Nursing practice
- Apply nursing ethics to medical-surgical nursing
- Summarize the role and actions of an ethics committee

Ethics is the framework that guides decisions related to patient care, and this guiding framework is important because lives are at stake. Nurses make life and death decisions daily, making ethics the foundation of integrity within the nursing profession. Ethical decision-making ensures the patient's autonomy is respected, equitable treatment is provided, and that the best care will be given in alignment with a patient's beliefs and values.

The ANA Center for Ethics and Human Rights was established to help nurses navigate the ethical complexities of life and death decisions commonly found in everyday practice. The ANA works diligently to develop ethics and human rights policy at the state, national, and international levels. Regardless of the present-day challenges in health care, the ANA's Code of Ethics for Nurses unites nurses while illustrating the integrity of the nursing profession and its promises to advocate for safe, quality care for all patients and all communities, regardless of socioeconomic status.

Code of Ethics for Nurses

As discussed earlier, the Code of Ethics for Nurses has been referred to by the ANA as the "social contract that nurses have with the U.S. public" (ANA, 2015, para 11). The Code of Ethics for Nurses is the foundation of the nursing profession's promise to provide and advocate for safe, quality care for all patients and communities. It creates unity among nurses to support each other to ensure nurses can fulfill their ethical and professional obligations.

The ANA points out that although the foundation of nursing care does not change, changes do occur in the structure, financing, and delivery of health care. The Code of Ethics for Nurses is updated regularly to address these changes to support nurses with the provision of respectful, humane, and dignified care, which is frequently challenged by the failings within U.S. health care and the associated negative social determinants of health. Despite the challenges, the Code of Ethics for Nurses personifies the proud ethical heritage of nursing that will be continued regardless of the challenges presented by the modern health-care system (ANA, 2015).

Ethics in Medical-Surgical Nursing

Ethical issues in medical-surgical nursing span a wide range of situations. Some of the more common situations involve questioning provider orders, the conflict between spirituality and science, use of opioids, end-of-life decisions, and the use of social media.

Questioning Provider Orders

It can feel intimidating to question a provider's order, but ethically, nurses have a responsibility to advocate for their patients' care and safety. Although nurses may not agree with a specific order from a provider, they cannot randomly decide to not follow an order without the possibility of facing disciplinary actions by their employer. It is the nurse's responsibility to follow the provider's orders. However, if an order seems incorrect or unclear, the nurse needs to call the provider for clarification.

However, when there is a safety concern, the nurse has an obligation to advocate for the patient by questioning the provider's order. For instance, one of the rights of medication administration is "right medication." If the nurse conducts a safety check and determines that a medication is not indicated, they should question the provider's order. If the provider insists on administering the medication, the nurse may need to move up the chain of command to speak to a provider in a higher position as well as notify the nursing supervisor of the situation. The alternative solution would be to administer the medication and risk the patient having an adverse outcome, which could create a risk to the nurse's license. Each individual state's Board of Nursing handles disciplinary action risking license suspension or revocation.

Cultural and Spiritual Implications

There may be situations in which nurse is presented with the dilemma of choosing a patient's spiritual preference versus an evidence-based scientific solution. For example, patients who are Jehovah's Witnesses do not believe in receiving blood products, yet these products may be needed in a life-threatening situation. A nurse can advocate for the patient by discussing with the provider the possibility of ordering epoetin instead of a blood product.

Although it is the duty of the nurse to present the evidence-based information to the patient so the patient can make an informed decision, it is equally important for the nurse to set aside their own personal beliefs to respect the patient's spiritual beliefs and decisions regarding their care. This is patient-centered care at its deepest level and requires a great deal of compassion from the nurse. Autonomy is the patient's right regardless of the evidence-

based information or scientific treatment presented, and beneficence is the nurse's duty to their patient.

Use of Opioids

The administration of opioids can create quite a dilemma. Although nurses have an ethical responsibility to manage the patient's pain and to provide comfort, nursing clinical knowledge indicates that high dosages of opioids can lead to respiratory distress and even death. Nurses also have to exercise caution when administering medications such as opioids to a patient with known or suspected substance use disorders who may request more than actually needed. To further complicate the administration of pain medication, some nurses are hesitant to administer large doses of pain medications to terminally ill patients. However, the risk of respiratory depression is not the intent of the action (the administration) and should not be used as an excuse for withholding the analgesia. Although it is important to report respiratory depression to the physician, the administration of pain medication should be governed by the patient's needs.

End-of-Life Decision-Making

End-of-life care and decision-making can be difficult for the nurse as well as for the patient and families. However, there is an established trust in the patient-nurse relationship, and the nurse is often looked to for guidance. It is important to set aside one's own beliefs to compassionately respect the patient's and family's beliefs and desires.

When a patient chooses to not be resuscitated if their heart or breathing stops, a verbal order is not sufficient. It is imperative to discuss this subject with all patients upon admission to ensure a DNR or DNI order has been signed by the patient (or their durable power of attorney) and placed in the patient's record. If the patient has an advance directive, it is also important to obtain a copy to be placed in the patient's record. Additionally, it is important to discuss the patient's wishes with the provider, which may lead to further communication with the family, especially if the family is afraid to let a loved one die with no efforts to resuscitate. Finally, compassion should also be extended to colleagues who are facing these difficult situations. Talking and listening can provide a level of needed support.

Maintaining Boundaries on Social Media

Social media and professional boundaries are challenging in today's world. Each generation of nurses comes into the nursing profession more technologically savvy than the previous generation, often resulting in a blurred line with professional boundaries, especially with the increased use of social media. The use of social media can also create a challenge in distinguishing between one's personal identity and professional identity. However, professional standards in the nursing profession are outlined by the ANA's Code of Ethics for Nurses. It is important to maintain one's integrity by adopting clearly established professional boundaries to support safe use of social media as well as to promote the future profession of nursing.

LINK TO LEARNING

When a hot topic arises in the industry, ANA will create an explanation, justification, or recommendation for a course of action, otherwise known as a position statement. Read the the ANA's position on social media use (https://openstax.org/r/77ANASocMedia) as it relates to the nursing profession.

Ethical Consultations and Ethics Committee

The hospital **ethics committee** is the primary source for dealing with ethical issues. Described in more detail later in the chapter, ethics committees provide support for health-care professionals when ethical challenges arise during clinical practice and are often consulted by nurses to help guide decision-making when ethical dilemmas are present during health-care delivery. The committee is composed of people of various professions, including physicians, nurses, clergy members, attorneys, social workers, and community members (Lifespan Health System, n.d.). As discussed earlier, avoiding ethical dilemmas is impossible, but having the knowledge to face these dilemmas is essential. The most important thing is to handle each situation in a professional manner that promotes quality care and patient safety.

Ethics committees provide support and guidance by:

- Adopting and promoting adherence of policies, procedures, guidelines, and staff bylaws

- Assisting in ethics-related educational programming and policy development within their institutions
- Assisting in facilitation of decision-making in individual cases
- Drawing upon resources of professional organizations to inform committee recommendations
- Protecting the confidentiality of information disclosed during discussions
- Respecting the rights and privacy of all participants
- Serving as advisors and educators

Summary

5.1 Clinical Judgment and Ethical Dilemmas

- Clinical judgement is guided by ethical guidelines as outlined by the ANA.
- Clinical judgement is based on nursing knowledge, critical thinking, and clinical reasoning which is then used to understand and interpret information related to the delivery of care and how it affects care outcomes.
- The principles outlined in the Nursing Code of Ethics are the foundation that guides nurses to provide high-quality, patient-centered care.
- Common ethical principles include autonomy, beneficence, justice, nonmaleficence, and fidelity.
- Autonomy is an ethical principle that acknowledges a patient has the right to make their own informed decision that should be upheld and respected by the interdisciplinary team.
- Beneficence refers to the nurse's responsibility to act in their patient's best interest, the duty to do good, which the ANA defines as "actions guided by compassion."
- Justice refers to the duty to treat all patients fairly and equally, regardless of social or financial status.
- Nonmaleficence refers to the duty to do no harm, which is a foundational principle of nursing practice.
- Common ethical issues faced by nurses involve topics such as confidentiality, the use of restraints, the maintenance of trust, and a variety of end-of-life issues that may be related to pain control, DNR orders, the use of life support, and the matter of continuing food and fluids.
- The ethical principles outlined by the ANA of autonomy, beneficence, nonmaleficence, and justice are a solid foundation for ethical decision-making. This foundation is a guide to help promote a logical, systematic framework for ethical decision-making.
- The approach to ethical decision-making can follow the steps of the clinical judgment measurement model, which includes recognizing and analyzing cues, prioritizing hypotheses, generating solutions, taking action, and evaluating outcomes.

5.2 Patient Care and Safety

- The nursing profession is accountable to society.
- Nursing has been named the most trusted profession for 21 years in a row.
- Nurses continue to use strong ethical principles during the delivery of patient-centered care.
- Navigating ethical dilemmas can take a toll on a nurse's caring nature.
- The ANA's Code of Ethics for Nurses is the foundation of the nursing profession's promise to provide and advocate for safe, quality care for all patients and communities.
- The Code of Ethics for Nursing with Interpretive Statements provides a systematic framework to help nurses navigate ethical dilemmas while also helping to preserve a nurse's caring nature.
- It is a nurse's duty to maintain confidentiality of all patient information, which includes personal and clinical information in the work setting as well as all venues when off duty.
- HIPAA created national standards to protect patient privacy by prohibiting health information from being disclosed without the patient's consent or knowledge except in certain situations to ensure continuity of care.

5.3 Ethical Patient Education

- Health education is essential to promote optimal patient outcomes.
- Health education is vitally important to nursing care because it promotes the ability of patients and families to improve their behaviors for optimal self-care.
- The function of teaching in nursing is included in state practice acts and the ANA Code of Ethics for Nurses.
- Nursing care is directed toward promoting, maintaining, and restoring health, preventing illness, and assisting people to adapt to the residual effects of illness.
- It is important to maintain an ethical mindset when providing patient education, to ensure the teaching focuses on what a treatment does and not what the nurse believes.
- Effective health education promotes individual and community wellness and is directly related to positive patient care outcomes.
- Teaching is an integral tool used by nurses to help patients and families adopt effective health behaviors and alter lifestyle patterns that create a predisposition to health risks.
- Patient education that considers health disparities, health equity, cultural and religious differences, and health

literacy is a win-win for the patient and the health-care team.
- Benefits of ethical teaching include improving health literacy and health equity, resulting in solid patient outcomes.

5.4 Ethical Challenges in Scope of Practice

- The ANA Code of Ethics for Nurses is the foundation of the nursing profession's promise to provide and advocate for safe, quality care for all patients and communities.
- The ANA Code of Ethics for Nurses creates unity among nurses to support each other to ensure that nurses can fulfill their ethical and professional obligations.
- There are many ethical dilemmas that can be encountered as a medical-surgical nurse, including issues with provider orders, cultural or spiritual conflicts with patients, end-of-life decision-making, and situations involving social media.
- The hospital ethics committee is the primary source for dealing with ethical issues.
- Ethics committees provide support for health-care professionals when ethical challenges arise during clinical practice and are often consulted by nurses to help guide decision-making when ethical dilemmas are present during health-care delivery.

Key Terms

advocacy act of pleading for a cause, idea, or policy
ethics committee appointed committee that provides support and guidance with ethical dilemmas to promote sound decision-making
fidelity duty to faithfully uphold one's commitments
health disparities preventable differences that underserved populations experience related to disease, injury, or violence that can negatively impact health
health education various learning experiences designed to promote behaviors that facilitate health
morality person's or society's idea of what is right or wrong; usually associated with one's behavior
multimodal having or using a variety of methods
self-determination moral and legal right to determine what will be done with and to an individual's person

Assessments

Review Questions

1. What term best describes a patient's right to self-determination?
   a. Justice
   b. Autonomy
   c. Nonmaleficence
   d. Beneficence

2. What term comes to mind when upholding the responsibility of a patient's best interest?
   a. Nonmaleficence
   b. Beneficence
   c. Fidelity
   d. Paternalism

3. You are asked by your supervisor to take photographs of residents and their family members during a holiday gathering at your long-term care facility. As a nurse, you recognize that HIPAA should be at the forefront of this decision. What action is most appropriate?
   a. Refuse to take the photographs because this is not your job responsibility.
   b. Take the photographs because the patients and families are smiling and appear happy as they enjoy the gathering.
   c. Take the photographs because it is a long-standing tradition at your facility.
   d. Refuse to take the photographs until you have received informed consent from all the patients.

4. You are a nurse manager for an acute care facility. What is an example of a statement from another nurse that indicates the need to provide additional education related to confidentiality and information security?
   a. "I refused to share my password with the new nurse in training on the unit."
   b. "I noticed an unattended computer in the hallway but did not have a password to log into it."
   c. "I don't pull up electronic records for other patients in our unit if I'm not providing their care.
   d. "I know Mr. Smith isn't your patient but would you mind proofreading my summary before I save it?"

5. You are caring for a high-risk pregnant patient. The patient and fetus are at a high risk for death. Some decisions will help promote the pregnant patient's life but create significant jeopardy for the fetus; other decisions will preserve the fetus' life at the expense of the patient's life. As the patient's nurse, what role is most significant in this ethical dilemma?
   a. Case manager
   b. Care coordinator
   c. Patient advocate
   d. Collaborator

6. As a nurse, you recognize that your patient does not have a good understanding of health information or how to make informed decisions based on information you have provided. What is a term or phrase that best describes this patient's knowledge deficit?
   a. Cognitive impairment
   b. Low health literacy
   c. Lack of willingness to learn
   d. Noncompliance

7. What is a true statement about teaching approach for ethical patient education?
   a. It remains the same regardless of cultural or religious practices or the patient.
   b. It is equal for all patients without consideration of health disparities.
   c. It considers psychosocial situation of the patient.
   d. It focuses on details the nurse learned when in nursing school.

8. What is a benefit of ethical patient education?
   a. Reduces the risk of readmission by increasing understanding
   b. Removes health disparities by providing equal education to all
   c. Decreases need for the patient to have additional questions
   d. Lowers patient expectations for health information

9. You are a nurse for a patient with diabetes who experiences frequent episodes of hypoglycemia (low blood sugar). You have noticed that the provider's order for the patient's insulin may put the patient at risk for hypoglycemia in the middle of the night. As your patient's advocate, what is an example of the most appropriate action?
   a. Mention to your nursing colleague that the provider's order was not well thought out.
   b. Administer the insulin as ordered and document the concern in the patient's record.
   c. Call the provider before administering the patient's insulin.
   d. Administer the insulin and inform the oncoming nurse to keep a close watch on the patient during the night.

10. What document has been referred to as a "social contract" for nurses to the public?
   a. The Health Insurance Portability and Accountability Act
   b. The ANA Code of Ethics for Nurses
   c. The Ethics Committee's Guidelines
   d. The Nurse-Patient Partnership

Check Your Understanding Questions

1. What is ethics?
2. Describe some differences between morals and ethics.
3. Differentiate equality and equity.
4. It is of utmost importance that nurses remain alert to situations that present incompetent, unethical, illegal, or impaired practices or actions that could result in harm to a patient. Describe some situations that might arise that would necessitate the nurse's attention.
5. Define health literacy.

Reflection Questions

1. Describe an ethical dilemma you have experienced in your clinical practice or personal life. How could you use the "Recognize and Analyze Cues" and "Prioritize Hypotheses and Generate Solutions" steps of the Clinical Judgement Measurement Model to weigh the ethical dilemma?
2. Why do you think nursing is considered the most trusted profession?
3. How might maintaining an ethical approach to patient education affect the nurse-patient relationship?
4. List some ways an ethics committee supports and guides ethical decision-making.
5. The spouse of your patient shares information with you about the patient that has not been revealed by the patient. How would you determine whether you should communicate this information to the patient's primary nurse?

What Should the Nurse Do?

Ms. Stein, a 45-year-old female patient, presents to the emergency department with severe abdominal pain. She reports a history of chronic digestive issues and recently underwent elective surgery for gallbladder removal. Her vital signs upon arrival are within normal range, but she appears distressed. Ms. Stein discloses concerns about the surgeon's decision-making process during her operation, raising ethical questions about the procedure's necessity. She feels inadequately informed about potential complications and alternative treatments.

1. What ethical principles might be applicable to Ms. Stein's situation, considering her concerns about the decision-making process and lack of comprehensive information?
2. What solutions could be proposed to address Ms. Stein's ethical concerns and improve her understanding of the surgical procedure?

You are caring for an older adult patient who has been newly diagnosed with type 2 diabetes mellitus. You are discharging the patient to home, and part of discharge instructions include educating the patient on the medications they will be taking at home.

3. How would you assess this patient's condition and psychosocial situation to determine how to best instruct them regarding their medications?
4. How would you modify your teaching plan if the patient was hard of hearing, visually impaired, or unable to read or write?
5. What are some specific benefits that might come of providing ethical education to this patient regarding their newly prescribed medication?

Mrs. Melton, a 52-year-old female patient, has presented to the medical-surgical unit with complaints of severe abdominal pain. She has a history of chronic kidney disease and diabetes. Her vital signs on admission include a blood pressure of 140/90 mm Hg, heart rate of 98 beats per minute, respiratory rate of 18 breaths per minute, and a temperature of 100.2°F. Mrs. Melton is visibly distressed and expresses concerns about her worsening abdominal pain. As a nurse, you need to consider the ethical principles outlined in the Code of Ethics in Nursing. Given her medical history, it is crucial to discuss the appropriate course of action with Mrs. Melton, ensuring that her autonomy is respected while considering beneficence and nonmaleficence. Additionally, the involvement of the hospital's ethics committee may be necessary to address complex decision-making involving Mrs. Melton's medical care.

6. Based on Mrs. Melton's medical history of chronic kidney disease and diabetes, how do you interpret the potential impact of these conditions on her current abdominal pain, and what additional information would you seek to refine your analysis?
7. Considering the ethical principles, what are potential solutions to address Mrs. Melton's abdominal pain while respecting her autonomy and ensuring beneficence and nonmaleficence?

Competency-Based Assessments

1. How might the nurse limit paternalism in health care?
2. Identify and analyze potential causes of an ethical dilemma when a patient requests the withholding of information about a serious diagnosis from their family. How would you approach this dilemma?
3. Discuss the potential ethical dilemmas a nurse might face when advocating for a patient's best interest.
4. As a working nurse, explain how you can address the challenges of balancing the duty to maintain confidentiality with ensuring effective interdisciplinary collaboration.
5. You are a nurse tasked with educating a patient about a sensitive medical condition. Discuss the ethical considerations you need to keep in mind when providing information about the diagnosis, treatment options, and potential outcomes.
6. Compare the outcomes of patient education that emphasizes ethical considerations versus scenarios in which ethics is not prioritized. What impact does an ethical approach have on patient outcomes and the nurse-patient relationship?
7. Define the ANA Code of Ethics.

CHAPTER 6

Comprehensive Health Assessment and Physical Examination

FIGURE 6.1 Applying Your Learned Skills To A Comprehensive Health Assessment And Physical Exam Should Be Organized And Follow A Logical Plan. (modified from work from *Clinical Nursing Skills*. attribution: Copyright Rice University, Openstax, Under Cc By 4.0 License)

CHAPTER OUTLINE

INTRODUCTION The comprehensive health history and physical examination help the nurse devise a plan of care for the patient. To complete the health history and physical exam successfully, the nurse must use effective communication, critical thinking, and clinical judgment skills. The development of these skills arms the nurse with a solid foundation for practice. The concept of clinical judgment is the basis for decision-making and requires the nurse to integrate all data they have on the patient, including subjective and objective information.

The nurse's ability to communicate effectively is essential to gathering complete and accurate data from and about a patient, collaborating with other providers to coordinate care, and facilitating open, empathetic conversations with patients. The nurse will rely on their critical thinking skills to analyze patient data and piece together the "puzzle" of how to approach care. They must be able to identify patterns and establish priorities for their patients based on the data they have gathered and analyzed. The nurse will use each of these skills when taking a history and performing an exam on a patient. For example, the nurse will use their communication skills to explain what will happen during the exam to ease a patient's anxiety, critical thinking to adjust their questions according to a patient's needs, and clinical judgment to recognize and assess the data they gather during the patient encounter.

6.1 Critical Thinking in Assessment

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define critical thinking
- Discuss the importance of critical thinking in nursing practice
- Explain the expansion of critical thinking to clinical judgment

Nurses use critical thinking skills every day, from one-on-one patient encounters in clinical settings, to the professional interactions they have with colleagues and the broader health care systems in which they work. Thinking critically means objectively considering and analyzing information and figuring out how to use it efficiently. According to the American Nurses Association (ANA), "critical thinking in nursing involves identifying a problem, determining the best solution, and implementing an effective method to resolve the issue using clinical decision-making skills" (ANA, 2024, para 3). It's a complex skill that incorporates education and training, experience, and available data. Critical thinking enables the nurse to make decisions that are well-informed, evidence-based, and **patient-centered**, which are decisions made with respect for the patient's interests, needs, culture, values, and preferences.

LINK TO LEARNING

You can read more about critical thinking (https://openstax.org/r/77ANAHub) on the ANA website.

This section defines critical thinking and explains why it is a foundation of nursing practice. The section will also tie critical thinking to another skill necessary for effective nursing practice—clinical judgment.

Critical Thinking Defined

Critical thinking allows the nurse to use rational standards to analyze information, interpret values/assessments, and ask questions about the data they obtain about a patient as part of a comprehensive health assessment and physical exam. Critical thinking is a skill nurses constantly use, and a skill that evolves with experience. Every decision the nurse makes is rooted in critical thinking. A nurse must combine assessment skills using the evidence of the physical exam to understand the patient's health concerns and help them achieve a positive outcome.

Critical Thinking in Nursing

The ability to think critically about information helps nurses make all kinds of decisions—from the day-to-day ones to the life-or-death ones. The nurse must consider all aspects of the data they have collected on a patient, whether it's going through current medications to check for potential interactions or assessing a patient's lifestyle risks. The nurse also needs to be aware of, and sensitive to, the different cues that patients give based on cultural diversity, gender, race, age, and ethnicity. There are also times when critical thinking can be more challenging, often because gathering data or being confident in those data may not be straightforward: for example, if a patient can't communicate clearly or if a nurse is contending with their own bias about a patient's situation. A nurse with critical thinking skills can make a split-second decision based on the health assessment that could save a patient's life. Even if not lifesaving, critical thinking skills help the nurse ensure positive patient outcomes.

REAL RN STORIES

Nurse: Sandy, BSN
Years in Practice: Eight
Clinical Setting: Primary care office
Geographic Location: A rural community in the Midwest

About a month ago, I had one of those "could have been worse" moments with a patient who showed up to the clinic for a routine annual physical, but ended up in the ER. Mrs. Kline is a 64-year-old patient at our office who was

simply coming in for a check-up. We're in a rural town, so it can sometimes be hard to get our patients to keep up with their annual screenings and visits since transportation can be a major issue. But Mrs. Kline always shows up like clockwork, remembers to bring her meds, is cheerful, compassionate, and always eager to update us on her grandchildren. She's one of those patients who is a joy to be around, really. So, when I came into the room to get her vitals and update her chart and saw her looking pretty downtrodden, my hackles went up.

"How are things going, Mrs. Kline?"

I was taken aback when she hesitated to answer—usually, she'd start chatting the moment I turned the doorknob. But on that day, she seemed discombobulated and uncomfortable. When she did start to talk, it seemed labored, like she couldn't catch her breath. She barely got out, "Oh, about the same as always, dear."

Well, clearly not!

"Mrs. Kline, how are you feeling right now?"

She winced a little, and her hand almost subconsciously touched her chest. "Oh, I'm just a little tired. I didn't sleep well last night."

I nodded, encouraging her to tell me a little more about what was wrong.

"Oh, I just had bad indigestion," she said. "But that's what I get for having a second bowl of rocky road!"

She tried to give me a smile, but I could see she was feeling pretty lousy. She was pale and appeared a little clammy. I asked her to tell me more about her symptoms, and she said that she'd been "feeling pretty nauseous" since last night and "had some gas up in her chest." I asked her to be a little more specific about that feeling, and she said it was "uncomfortable pressure."

I took her vitals, and her temp, RR, and O2 were normal, but her BP was a bit lower than I would have expected, and her heart rate was a little up.

I knew I still needed to do med reconciliation and ask her about any other changes, but it seemed like whatever was going on with her today needed to be the priority. As I was documenting the findings in her chart, Mrs. Kline started to get out of the chair, "I'm sorry, I think I need to use the restroom. . ." but as she stood, I could see how unsteady she was on her feet.

"Mrs. Kline, I'm very concerned about your symptoms," I said, helping her back to her chair. "I think we need to put your annual check-up on the backburner for now."

"I'm fine," Mrs. Kline insisted, "I think I just caught a little bug. . ."

"Could be, but I'd feel a lot better if we had Dr. Richards come in now," I said, reaching for the phone. I called up to the front desk and let them know I needed Dr. Richards to patient room 2, and she appeared just a moment later. She knew Mrs. Kline as well as I did, and the minute she looked at her, she also could tell something was really wrong. I gave her report quickly and she did a quick exam. Then, she said, "Mrs. Kline, I'm concerned that you could have having symptoms of a heart attack. I'm going to have Sandy call an ambulance to take you to the ER."

Mrs. Kline almost laughed, but painfully grimaced as she spoke. "Don't make a fuss over me," she said, "If you're worried, I could just drive. . ."

"Mrs. Kline, the nearest ER is 40 minutes away," I said gently, "And we want to get you there ASAP. The ambulance is the fastest and safest way."

She sighed, but almost seemed relieved. "Well, I guess I don't want to risk getting a ticket, right?"

Dr. Richards and I tried to give her a reassuring smile, but we were both nervous. By the time EMS arrived for transport, Mrs. Kline had started trembling and felt like she was going to pass out. As we sent her off, we wondered if she'd make it.

It was a few hours before we knew anything, but Dr. Richards came to the break room around lunch time to let me know that Mrs. Kline had an NSTEMI.

"I'm glad she came in for her annual," Dr. Richards said, "If she'd just been at home today, she probably just would have kept writing it off as indigestion. But I'm also glad that you did her intake—even though she wasn't a high-risk patient, you put the pieces together and probably saved her life."

While I did feel relief and a little bit of pride knowing that I'd done the right thing for the patient, I didn't let it go to my head. As nurses, we make quick but well-informed decisions every day, and yes, sometimes they're life or death. But it was really a team effort, from the coordination in our office to the EMS crew and the ER staff.

Critical thinking can be defined as habitually using a set of rational standards to guide decision-making (University of Tennessee Chattanooga, n.d.). Critical thinking skills allow nurses to gather a more complete picture when they are assessing and examining a patient. At times, what a patient is saying may not match what the nurse observes. The misalignment does not always mean the patient is lying. While critical thinking skills can help nurses identify when a patient is being untruthful or has limited health literacy, these skills are also crucial for helping the nurse identify barriers that can make it harder to get an accurate and cohesive picture of a patient's health. Patients may not understand why they need to share certain information with their health care providers or the consequences of withholding that information. They may struggle to recognize or remember information that would be useful for them to share during a visit. Patient factors, such as cognition, communication, social stress, mental health, cultural background, personal beliefs, and health literacy level, also affect how they communicate with the health care team.

For example, consider a scenario where the nurse is talking to a patient with dementia. Due to their cognitive condition, the patient may give answers to the nurse's assessment questions that don't line up with what the nurse is observing or expecting. The patient is not lying intentionally, but they are unable to be a reliable historian/informant about their own health. A patient with dementia may state that they do not take any medications, but the nurse can see in the patient's chart that they are prescribed several drugs to manage multiple chronic conditions, and the nurse may also know that the patient was administered a medication earlier that day. A patient with dementia may not recall any of their current health conditions and may not be able to describe their present state of health or concerns. The patient may say they feel "great," but the nurse may question that statement if they note an elevated temperature and heart rate.

To ensure a holistic picture of the representation of the patient, the nurse uses critical thinking skills during the comprehensive health assessment and physical examination to explore a patient's whole person needs. A comprehensive assessment and physical examination include not only details about physical state of health, but also the emotional, social, psychological, spiritual (Ambushe et al., 2023), cultural, sexual, energetic, and environmental aspects of a person's life (ANA, 2019). These factors impact the health and well-being of the individual and are important in planning care for current health problems and preventative care (Figure 6.2).

Critical Thinking in Clinical Judgment

Integrating nursing knowledge and experience with the data collected and analyzed to make informed decisions about patient care is called clinical judgment. Clinical judgment will evolve with experience. Over time, nurses also develop a degree of **intuition**, or a "sixth sense" of knowing that largely comes from years of education and problem-solving in real-world patient situations. But even experienced nurses who have a sense of intuition must still call on their critical thinking skills; they would not simply rely on intuition alone.

One framework that explains how to transition from critical thinking to clinical judgment is the Clinical Judgment Measurement Model (CJMM). The process outlined in the model has several components (NCLEX, 2024):

1. Recognizing cues: The nurse will acquire data from different sources, including the patient and medical records. They will identify specific facts or details within the data from assessments, patient conversations, and records to look for cues that will inform how they will approach caring for the patient.
2. Analyzing cues: The nurse will take the patient's needs into account and use the data to identify problems and create priorities. This includes organizing and analyzing the data to look for outliers or trends.
3. Prioritizing hypotheses: The nurse uses the data and analysis to set priorities based on the possible causes of the patient's condition and making sure that the most important problems are addressed first. They will work with an interdisciplinary team who is involved in the patient's care to set goals.
4. Generating solutions: The nurse will come up with possible interventions based on the patient's needs, interests, and evidence-based practice (EBP) from current literature.
5. Taking action: The nurse will objectively look at the interventions and assess how effective they are for the patient. They do research and seek insights from the interdisciplinary team to improve the patient's care plan. Ultimately, the overall goals and steps taken are nurse driven.
6. Evaluating outcomes: The nurse will look back on the clinical judgment process and identify areas of strength and weakness. They ask for feedback from colleagues to help them get an objective view of their skills, decision-making, and judgment.

REAL RN STORIES

Nurse: Mina, RN
Years in Practice: Ten
Clinical Setting: Renal department of a hospital
Geographic Location: Southeastern region of the United States

I've worked in the medical renal department for about 10 years now, but I still have moments when I feel like a nursing student solving a textbook patient puzzle! Recently, I cared for a 54-year-old male, Mr. Chen, who was admitted for shortness of breath. Mr. Chen had a history of diabetes and hypertension. During the assessment, he reported that he hadn't been able to walk down his driveway to get the mail and had gained two pounds in the last three days. He also reported weakness, lack of motivation, and trouble sleeping. In my thinking-it-through process, I paid attention to these subjective statements or "cues" the patient was giving me.

As I was entering data in his chart, I noticed that Mr. Chen took blood pressure medication, insulin, and a diuretic. I did medication reconciliation to confirm that he was still taking these prescriptions as directed. As I was doing the assessment on Mr. Chen, I noted swelling in both of his feet and a respiratory rate of 24 breaths/minute at rest. When I put my fingers against the bottom of his legs by his ankles, they left an indentation. These objective findings got added to my subjective cues from earlier. I started to piece together what I knew about Mr. Chen from his medical record, what he'd told me, and what I was observing based on the physical exam. Once I had all the data gathered, it was time to think about what it might be trying to tell me. Putting it all together, I realized that this patient's presentation could have been a textbook example of acute kidney injury or heart failure; either way, I knew Mr. Chen needed to be the provider's priority.

6.2 Effective Communication in the Nurse-Patient Relationship

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss maintaining a professional nurse-patient relationship.
- Describe methods of communication in medical-surgical nursing
- Define models of communication about patient care

Nurses develop and maintain various professional relationships in their careers, such as those with colleagues and mentors. The nurse-patient relationship is unlike any other professional or personal relationship. It is essential that nurses understand the rules that govern this unique and important relationship to protect themselves and their patients. This section defines the nurse-patient relationship and explains how it is established and maintained. It also discusses communication methods used in medical-surgical nursing, including the models that are used to convey information about patient care.

The Nurse-Patient Relationship

The path to becoming a nurse takes time, energy, resources, and dedication. As nurses progress through their careers, they gain knowledge, develop their skills, and hone their intuition, all while maintaining their values and having their own life experiences. Yet every patient they encounter will also bring their own needs, beliefs, and life experiences to the nurse-patient dynamic. Balancing each side of the relationship requires a deep understanding of effective communication, the nuances of human behavior, emotional intelligence, and cultural competence. The nurse must also be versed in the state and federal laws and regulations that govern the nurse-patient relationship.

The ability to forge therapeutic relationships with patients is central to patients' experience of receiving care (Molina-Mula & Gallo-Estrada, 2020), and the relationship serves more than one function. For the patient, the relationship is a safe, supportive space for asking questions and expressing needs. For the nurse, it is an invaluable tool for providing compassionate care (ANA, 2023). In both facets, the nurse-patient relationship can evolve and change over time. Given how important and complex the nurse-patient relationship is, there are standards of care and scopes of practice to guide the formation and maintenance of these beneficial and effective partnerships with patients. These guidelines also ensure that the nurse-patient relationship is appropriate and safe for everyone involved.

CULTURAL CONTEXT

Nurse-Patient Relationship for Muslim Patients

Islam is the second largest religion in the world, and non-Muslim nurses may find themselves caring for Muslim patients. Asking Muslim patients questions and listening actively to their answers creates a safe space for discussing religious and cultural needs a Muslim patient may have. Many Muslim patients pray multiple times a day; spiritual practices are an important part of the healing process. It is important for the nurse to respect religiosity, dietary restrictions, the strong patriarchal presence, and the preference of female nurses for female patients when caring for Muslim patients. Accommodating such cultural needs enhances the nurse-patient relationship by showing that the nurse cares about the unique religious needs and customs of their patient (Alfar, 2023).

The pillars of the nurse-patient relationship—trust, respect, empathy, and communication—are foundational to most other important relationships as well (Allande-Cussó et al., 2021). The nurse needs to understand other key elements, such as power imbalances and breaches of confidentiality, that have the potential to weaken rather than strengthen the nurse-patient relationship.

The nurse can uphold the pillars of this special dynamic by conducting the relationship within professional boundaries. A **professional boundary** is the clear separation between personal and work life when interacting with patients, designed to protect both the patient and the nurse. While the nurse must establish and then maintain professional boundaries at all times, it is not always easily done. The nurse must strike a balance: they need to be empathetic without being too personal. They need to use therapeutic intimacy from a professional and objective distance. They must nurture a rapport with patients but not befriend them. Although the nurse-patient relationship

exists within the safety of professional boundaries, it does not mean it has to be unfeeling or cold. The nurse will always respect the patient and work to earn their trust. Professional boundaries are a way to recenter the patient as the focus of care and prevent violations that could undermine trust and erode the therapeutic relationship (National Council of State Boards of Nursing, 2018).

Establishing and enforcing boundaries is the nurse's responsibility, not the patient's. At times, professional boundaries may blur or be challenging to maintain. The nurse may even unintentionally cross a line without realizing it. This is why it's crucial for the nurse to take a proactive approach to prevent lines from being crossed within the nurse-patient relationship. Here are just a few examples of potential boundary violations that nurses may encounter:

1. Oversharing personal information with patients
2. Being too emotionally vulnerable with patients
3. Touching patients in any nontherapeutic way that could be construed as overly familiar or potentially romantic/sexual
4. Uncomfortably infringing on a patient's personal space (e.g., sitting very close to them on the bed)
5. Talking about patients with family or friends
6. Posting about work experiences on social media and/or sharing personal information on public accounts (HIPAA violation)
7. Adding patients on social media (HIPAA violation)
8. Spending time with patients outside of work in a way that would be considered more of a casual friendship (e.g., taking part in shared hobbies together)
9. Accepting gifts, money, or any business-type exchange with patients

It may seem that these boundary violations would be obvious, but they can be subtle and exist more on a spectrum than being clear "stop signs." For example, a nurse who lives and works in a small community may frequently run into patients at the grocery store. They might be members of the same gym or have children that attend the same school. These interactions will not always be avoidable, and the nurse still needs to maintain professional boundaries. The nurse must be vigilant and ensure that their behavior is always professional and focused on the patient.

Methods of Nurse-Patient Communication

The nurse-patient relationship hinges not only on trust, respect, and empathy, but also on communication (Afriyie, 2020). It is only through effective, therapeutic communication that the nurse can establish trust and rapport with the patients in their care (Kwame & Petrucka, 2021). Effective, therapeutic communication begins as soon as nurses introduce themselves. Throughout the course of providing care, the nurse will evaluate and adjust their communication strategy to ensure that it is effective for the patient. One of the most basic examples, and also one of the easiest for a well-educated and experienced nurse to forget, is avoiding medical terminology (Afrieye, 2020). All information and teaching provided to the patient must align with their health literacy level. This means not using medical jargon, including acronyms, that may confuse or intimidate a patient. If a patient cannot understand the nurse's language, they won't be able to comprehend why the information the nurse is providing is important to their care. Effective, therapeutic communication also allows the nurse to gather data for clinical decision-making. For example, using open-ended rather than closed questioning helps the nurse gain valuable information from the patient and transition the assessment to the next phase of nursing care. (Table 6.1). In the nursing process, the next step would be to identify the nursing diagnosis and formulate a plan of care. In the CJMM, the nurse would next analyze cues and prioritize hypotheses.

	Therapeutic Communication	Nontherapeutic Communication
Offering self	Friendly, approachable, and inviting. When appropriate, use "we" and "us" instead of "you" or "I" to show unity and inclusivity.	Formal, guarded, and distant. May use "I" and "you" to emphasize individual roles.
Communicating nonverbally	Relaxed body language, open posture, consistent but comfortable eye contact, and active listening.	Tense body language, crossed arms, avoidance of eye contact, and minimal nonverbal feedback.
Encouraging elaboration, seeking clarification	Encourages questions and listens to different viewpoints. Asks open-ended questions to promote deeper discussion and help patients feel more at ease expressing their thoughts, concerns, and preferences.	Discourages or dismisses questions. Asks closed-ended questions ("yes" or "no") that limit responses or make patients feel cut-off and hesitant to share more about what they are thinking or feeling.
Giving information	Proactive in sharing information, values transparency, and explains the reasoning (or "why") behind decisions.	Reluctant to share information, prefers to keep things private, and may be secretive about decisions.
Restating, reflecting, summarizing	Actively listens to others, "teaches back" what they have heard to confirm understanding, and values feedback.	Appears disinterested in what others have to say, interrupts frequently, and dismisses feedback.
Encouraging collaboration	"What are your thoughts on this?" "How can we work together to achieve this goal?" "I'd like to hear what you have to say."	"You just need to do what we tell you to do." "Did you take your medication like you were supposed to or not?" "I don't have time to listen to your concerns."

TABLE 6.1 Effective, Therapeutic Communication

Imagine that a patient presents with a weeping (fluid-oozing) rash on his leg. The nurse can ask an open-ended question like, "What can you tell me about that rash I see on your leg?" or phrase it as a statement such as, "Please tell me about the rash I see on your leg," to open the door for further exploration into the patient's health. On the other hand, a question such as, "I see your left leg has a weeping rash. Did you tell your doctor?" is closed-ended. Here, the patient can only answer yes or no; they have either told the doctor about their rash or they have not. This question does not give the patient a natural opportunity to tell the nurse more about the rash and provide the crucial details necessary for a comprehensive assessment. In this example, the closed-ended question, "Did you tell your doctor?" could also make the patient feel judged or even guilty. If they have *not* told their doctor about the rash, they may feel that they've "been bad" and worry about what the nurse will think of them.

To communicate nonjudgmentally and without bias, the nurse constantly needs to reflect on both their verbal and nonverbal communication with patients. Nurses need to be self-aware and willing to correct their behavior if it's not contributing to open, effective, and compassionate communication. This requires a critical appraisal of their actions and words and an honest look at their beliefs and perceptions.

Effective communication in health care is not just verbal; it also includes nonverbal, written, and visual communication. The spoken word, in whatever language the patient can best communicate and understand is **verbal communication**. Physical movements or motions, including body language, that convey thoughts, attitudes, and sentiments to a patient are methods of **nonverbal communication**. A type of nonverbal communication based on physical movement and expression is **body language**. Reinforcement of verbal information given to the patient in a format they can read is considered **written communication**. Strategies like return demonstration can confirm a patient's understanding and is considered **visual communication**.

During the comprehensive physical assessment, the nurse will use verbal and nonverbal communication with patients. While verbal communication is the most effective, nonverbal communication can enhance the assessment by allowing the nurse to convey attentiveness and empathy. Nonverbal communication also has potential pitfalls, however, of which the nurse must be aware. Body language, facial expressions, eye contact, tone of voice, physical distance, and touch are all facets of nonverbal communication that can either enhance or hinder the nurse-patient relationship. Nurses have to be conscious of their own nonverbal cues, as even unintentional signals can convey messages contrary to their intended communication. An open, relaxed posture, appropriate eye contact, and a warm smile can foster trust and reassurance, and help build rapport with patients. On the other hand, closed-off body language like crossed arms, frowning, or excessive distance may send the message that the nurse is disinterested, disapproving, or unempathetic.

The nurse also needs to attentively observe—and interpret—a patient's nonverbal cues. An averted gaze, fidgeting, or incongruent facial expressions can indicate discomfort, fear, or confusion—even if what the patient says to the nurse conveys the opposite. Nurses have to integrate a patient's nonverbal cues with verbal communication to fully understand their needs.

There are many layers to understanding and interpreting nonverbal cues from patients, and it's not always as simple as paying attention to what they do and say. Cultural competence is critical to understanding nonverbal communication because different cultures ascribe different meanings to the same gestures, expressions, or social norms and concepts. What may be perceived as respectful in one cultural context could be seen as offensive or inappropriate in another. Making eye contact during a conversation and maintaining "personal space" are just two examples of relatively common aspects of nonverbal communication that are very culturally dependent. Nurses need to continually educate themselves about the cultural backgrounds and customs of the communities they serve to ensure they are providing culturally sensitive care.

Active Listening

Communication is not just about how the nurse speaks but also about how they listen. The nurse should strive to be an active listener when the patient is talking (Tennant & Toney-Butler, 2022). This means that they don't just hear but seek to understand what the patient is telling them.

To be an active listener, fully focus on the patient. One way to demonstrate openness to listening is simply looking at them or turning toward them. Taking a seat so that they can be at a similar level as the patient is also helpful, as standing over them can be intimidating. Avoid interrupting the patient as they are speaking. Use supportive statements and phrases to acknowledge what they have shared ("I understand that sharing these details is difficult for you. . ." and "It sounds like you are worried about. . .") and encourage them to elaborate or clarify ("Tell me more about that. . .").

When they are done sharing, the task of summarizing or explaining the message received gives patients a chance to correct any misunderstandings or offer more details. It also gives the nurse an opportunity to demonstrate empathy and understanding and develop trust further.

Communicating with Patients Who Speak a Different Languages

English may not be the first language of all patients. When nurses do not speak the patient's preferred language, the communication barrier can make it challenging to develop the nurse-patient relationship and gather a comprehensive health history and physical assessment.

Cultural awareness and competency guide nurses working with patients who have a preferred language other than English. To begin, the nurse must determine a patient's language preferences and decide what steps to take to ensure that the patient's needs are understood and met. It is the legal responsibility of a facility to provide language services for patients that meet certain standards (U.S. Department of Health and Human Services, n.d.). The nurse must know what language resources are available to them. Each health care organization has assistive technology that staff can use to communicate with patients. One example is Martti, a translation technology solution that integrates with EHRs, as well as tablets and mobile devices (Cloudbreak, n.d.).

The nurse should not use patient family members or nonapproved translators to communicate medical information. While a patient's family may be trying to help, medical translation is more complex than translating everyday conversation; it requires expertise (Villanueva, 2023). It is also not appropriate for a family member, such as a

patient's child, to translate for them, as it could allow for the transmission of personal medical information to someone who is not authorized to receive it or lead to a miscommunication if the family member is not well versed in medical terminology.

Using an approved translation service allows the patient to understand and answer the nurse's questions, which ensures the comprehensive physical and psychological assessment will be accurate. While the nurse should generally avoid "yes" or "no" questions, the simple binary can be helpful when there are language barriers, and the patient needs to communicate basic—but important—information to the nurse.

LINK TO LEARNING

A nurse who is multilingual may want to consider becoming a certified medical interpreter. The National Board of Certification for Medical Interpreters (https://openstax.org/r/77NBCMI) is one organization that offers certification in Spanish, Russian, Mandarin, Cantonese, Korean, and Vietnamese.

Communicating with Patients Who Have Auditory Impairments

Communication barriers can also emerge for reasons other than language. For patients who have auditory impairments, the nurse will again need to be aware of the resources available to help them complete a comprehensive health assessment and physical exam and provide care for the patient. A patient with total or significant loss of hearing would need approved assistive technology or sign language interpretation to ensure that the questions the nurse needs to ask are heard and understood.

Considerations that the nurse should keep in mind when speaking to patients who are deaf or who have hearing impairments including:

1. Assessing, identifying, and arranging for a patient's needs to be met.
2. Use a qualified sign language interpreter when needed. Do not rely on the nurse's basic skills or interpretation provided by a family member.
3. Confirming with the patient that their hearing aid (if applicable) is on and functioning in the setting.
4. Making sure the room is adequately lit and there are no distractions.
5. Facing the patient and maintaining eye contact while speaking to them.
6. Speaking clearly and articulating each word (but do not overly exaggerate or speak too loudly).
7. Being intentional about using body language and gesturing, as appropriate.
8. Using visual aids, as appropriate (Centers for Medicare and Medicaid Services, 2023; HLAA, 2023; National Association for the Deaf, 2018).

The nurse will need to adjust their approach to suit the patient's needs. For example, perhaps they planned to use a sign language interpreter for a deaf patient but discover that the patient is comfortable lip reading. In this case, they may not need the interpreter, and can adjust the plan so that they speak clearly and slowly to the patient and check for understanding frequently. In some health care settings, however, lip reading may be impossible, for example, because a provider is wearing a mask (Berry, 2021). The nurse also must consider that relying on writing to communicate with any patient can lead to misunderstandings, especially if the patient has low literacy or, more specifically, low health literacy. But for deaf patients who sign, the nurse should also keep in mind that American Sign Language (ASL) is not based on spoken English; there can be mistranslations just as there would be for other bilingual patients. In addition to being ineffective, writing can also be time-consuming and impractical for both the nurse and the patient, particularly in an emergency (National Association for the Deaf, 2018).

LIFE-STAGE CONTEXT

Considerations for Older Patients with Hearing Loss

One factor to consider when adapting nurse-patient communication to various clients is age. If taking care of an 85-year-old patient, be aware of how the aging process can affect communication and care. When conducting the assessment, notice concerns that the patient expresses both verbally and nonverbally. While talking to the patient,

notice, for instance, if the patient leans in closer to hear the questions. This observation will make clear that the patient may be having a hard time hearing the questions. It could be that the patient was brought into the hospital via ambulance, and the EMS crew did not retrieve the patient's hearing aids from their home. Perhaps the patient is embarrassed about their hearing loss and does not want to express that they are struggling.

The nurse should adjust their assessment to put patients of all ages and abilities at ease and ensure they understand the assessment questions. By focusing on the patient's needs and taking steps to address them, the nurse is fostering a trusting patient relationship, promoting effective communication, and ensuring that the data gathered are comprehensive and correct.

All patients, regardless of their communication needs, benefit from using the teach-back strategy to demonstrate their comprehension of the information the nurse has shared. The strategy, which involves having the patient explain the teaching provided to them in their own words, is an invaluable tool that helps the nurse assess for and quickly correct any gaps in knowledge or misunderstandings.

FIGURE 6.3 Nurses must be skilled communicators not just with patients but with other members of the health care team who are providing care for their patients. (credit: Staff Sgt. Samuel Morse/U.S. Air Force, Public Domain)

Models of Communication About Patient Care

Communication between the nurse and patient needs to focus on being effective and therapeutic. Communication with other health care professionals about patient care has a different goal completely. Communication about patient care is more direct, more streamlined, filled with jargon, and often requires one health care professional to convey the seriousness of a situation in as few words as possible so as not to delay care. Two models of communication health care professionals use with one another are Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) and ISBAR. These two models enhance teamwork, efficacy, and efficiency in communicating about patient care, and thus enhance quality of care.

INTERDISCIPLINARY PLAN OF CARE

Admission to the Observational Unit Interdisciplinary Plan of Care

The interdisciplinary plan of care for a patient being admitted to the observational unit for diabetic venous ulcers and possible sepsis can involve several health-care disciplines working collaboratively. Members of the team may include physical therapists, respiratory therapists, case managers, dietitians, and a wound care nurse, each with their own role.

1. The physical therapist (PT) aims to improve the patient's mobility and strength, initiating ambulation within 24 hours, if medically capable, and conducting range-of-motion exercises to increase strength and endurance of all the extremities.
2. The respiratory therapist (RT) focuses on promoting oxygenation and improved cardiovascular health with activities of daily living. The RT provides education on supplemental oxygen or any needed adaptive breathing equipment.
3. The case manager (CM) assesses psychosocial needs, offers emotional support, and facilitates counseling for adjustment. The CM also arranges care across all disciplines, develops comprehensive care plans, and arranges any necessary post-discharge services.
4. The registered dietitian (RD) optimizes nutrition for healing based on the patient's compromised condition and advises the patient on dietary adjustments related to other comorbidities to prevent future decline.
5. The wound care nurse (WCN) monitors the patient's skin integrity, educating on proper risk factors, preventative measures, and infection control. The WCN intervenes promptly in case of complications.

Together, these interdisciplinary team members ensure a person-centered approach for providing support, as patients are admitted to a medical facility. Each health-care organization has a long list of specialty team members to meet the needs of the patient they serve.

TeamSTEPPS

Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) is a training resource from The Agency for Healthcare Research and Quality (AHRQ) and the U.S. Department of Defense (DOD). The tools were developed by applying military teamwork, operations, and communications concepts and strategies to health care (American Hospital Association, 2023).

The four core competencies of TeamSTEPPS will be familiar from nursing education:

1. Team leadership: Delegating and coordinating tasks, motivating others, providing needed resources for optimal performance
2. Communication: Effectively conveying information through different strategies
3. Situation monitoring: Establishing and maintaining an agreed-upon way to monitor team performance
4. Mutual support: Knowing team member needs and taking steps to meet them

Nurses can be trained in the approach and apply the teaching to their work to enhance teamwork and patient outcomes. Nurses may use the TeamSTEPPS framework in a variety of clinical situations, such as when they are providing reports at the start of shift, including a patient's family in important treatment conversations, speaking up when they notice that a staff member is fatigued and may be unable to perform their duties, and participating in debriefs after procedures.

TeamSTEPPS has some similarities to another framework that nurses are familiar with—QSEN, which is often encountered early on in a nurse's education. While TeamSTEPPS is more focused on strengthening health care teams and QSEN is more about the individual nurse, both frameworks consider teamwork and communication to be core competencies in health care quality and safety. One main difference is that in QSEN, there are six focused competencies, of which teamwork and safety are two. These concepts are more of an embedded thread and driving force behind the overall framework in TeamSTEPPS. Because there is significant overlap, nurses often use both frameworks when providing care.

LINK TO LEARNING

Review AHRQ's TeamSTEPPS (https://openstax.org/r/77AgencyHRQ) and think about how to use these tools and resources in nursing practice.

ISBAR

The nurse is the patient's advocate. Effective communication with others in the interdisciplinary team is necessary to provide effective, coordinated, and patient-centered care. When communicating with other health professionals about patients, one evidence-based practice to use is ISBAR: identify, situation, background, assessment, and

recommendation (see 1.2 Intercollaborative Care). The ISBAR format allows nurses to efficiently and effectively communicate the information gathered on a patient during the comprehensive physical history and assessment. For example, a nurse who is handing off a patient to a colleague at the end of their shift can use the ISBAR framework (Table 6.2).

Component	Example
Identify the patient	"I'm Laurie Done, RN, and have been caring for Mrs. Martinez in room 204 today."
Explain the situation	"Mrs. Martinez was admitted last night from the ER with a complicated UTI and started on IV ceftriaxone."
Give background	"She has a history of UTIs. No known drug allergies. Her current medications are lisinopril and Zoloft."
Provide most recent assessment data	"Her vitals are stable, and she voided cloudy, yellow urine at 1450."
Offer recommendation	"I recommend encouraging oral hydration, monitoring her vitals, and continuing to administer medications as prescribed."

TABLE 6.2 ISBAR Use in Nursing Example

Once the receiving nurse has the information on the patient, the nurse can answer any questions or provide clarification before completing the hand-off.

6.3 Health History

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss how to obtain a comprehensive health history
- Discuss the different parts of the comprehensive health history

The health history of a patient provides direction for their care and helps clarify the patient's needs. There are two main nursing assessments: a focused health history and a comprehensive health history. A focused health history is tailored to the reason the patient's **chief complaint**, or the reason the patient is currently seeking care. The patient's health history, in this case, relates to exploring the chief complaint. When performing a comprehensive health history, the nurse must address the patient's problem in depth. At this level, the nurse will ask about the present illness but also about past medical history, allergies, social factors, lifestyle habits, and health risks, including family history. This assessment is a more thorough examination of the patient's overall health history and captures the various factors that affect a patient's health.

Obtaining a Comprehensive Health History

The most common way to obtain a health history is by interviewing the patient. As a nurse, there are some best practices to keep in mind when gathering this crucial health information. Make sure that the room is conducive to clear, effective communication. The space should be private, comfortable, and as free from distraction as possible. The nurse should then "prime" the conversation by building rapport and trust. Being an empathetic, active listener, ensuring communication needs are met, being self-aware, and keeping cultural and age-related factors in mind are all key to getting the information the nurse needs from the patient.

Following regulatory and institutional policies, procedures, and protocols for data gathering and recording may make this process more efficient, accurate, and streamlined. Following structured formats and using technology are among the key practical aspects of obtaining a health history. This may include using questionnaires to assess specific patient problems and knowing how to navigate and document in the patient's electronic health record (EHR). Throughout the process of data-gathering, nurses must observe how the patient is responding and adjust to facilitate effective communication. The nurse needs to continually monitor their own behavior and recognize when

their body language may be communicating a message to the patient that they do not intend. One common mistake nurses may make is staring too long at a computer screen while documenting, leaving the patient feeling isolated and ignored in the exam room. Try to maintain focus, both visually and verbally, on the patient. When the nurse has to attend to the computer, they should explain to the patient that reviewing and documenting relevant information helps with clinical decision-making. This way, the patient should not feel ignored. A nurse's position in the room can make a patient feel more open or closed off throughout the dialogue. For example, a nurse who is standing completely behind the rolling computer cart versus being seated, facing the patient, and "on their level" may be perceived to be less engaged, concerned, or empathetic (Lanier et al., 2021; Misto et al., 2019).

There will be times when the nurse needs to do a bit of problem-solving when obtaining the patient's history to establish clarity. If the patient is unable to provide a history, then the family can be interviewed to obtain the information. If the patient has brought many health documents with them, such as a list of medications or health conditions, notes on their surgical history, and/or advanced directives, this information may help the nurse piece together a complete history, along with what can be gathered from the patient's social and family history through interviewing. By assembling the components, the nurse gives the provider and care team a strong starting point to pursue the diagnostic puzzle and create a patient-centered, evidence-based treatment plan.

From the overall perspective of clinical practice, a focused (as opposed to comprehensive) assessment helps address the shortage of time that burdens the health care system at every level. Being efficient but thorough in gathering data respects the nurse's and patient's time (Figure 6.4). While the nurse must understand that each patient has a multifaceted and complex life, it is often necessary to focus the health history on the patient's current health. To ensure that the nurse is able to gather relevant data efficiently and accurately, they will need to guide the patient through the interview and maintain the focus on why they are seeking care from the provider at the present time.

FIGURE 6.4 Nurses have to collect and organize a lot of crucial information about patients, but there are a number of established frameworks to help them document a patient's history and physical exam findings. (credit: "Nurse with mask on, on the computer" by Rashid Mohamud/Flickr, Public Domain)

For example, a common chief complaint is pain. To help the provider solve the problem, the nurse will talk to the patient and recognize cues about the cause or source of the pain, as well as analyze and hypothesize how the pain could be treated or managed. The history, in this example, is not always one that is "far back" in the patient's life. Instead, it might be just a few days or weeks ago, depending on when the pain began.

Asking specific, open-ended questions like "How long have you had the pain?" gives the patient a chance to elaborate on what they're experiencing and supply the nurse with data. Asking more questions, such as whether

there is anything that makes the pain better or worse, and inquiring about associated symptoms (e.g., nausea), creates a more complete picture of the patient's problem.

Elements of the Comprehensive Health History

The elements of the health history help the nurse gather data to support the patient's current health concern. The format has several general components (UCF College of Medicine, 2018; Nichol et al., 2024):

- Chief complaint: Patient's specific, current problem (e.g., cough, sore throat)
- History of present illness: Details about chief complaint (e.g., duration and intensity)
- Past medical history: Chronic illnesses, mental health conditions
- Surgical history: Any procedures or surgeries
- Medications: Current prescriptions, over-the-counter (OTC) supplements, herbal remedies, or vitamins
- Allergies: Environmental, drug; details of symptoms, reactions
- Family history: Medical conditions, genetic disorders, risk factors
- Social history: Lifestyle habits, diet, physical activity, sexual health, living situation
- Review of systems (ROS): Allows the nurse to obtain specific, objective data on a patient's health by assessing each body system, one by one
- Social determinants of health: Sociocultural factors that may influence a patient's health

The ROS, physical exam, diagnostic tests, problem list, summary, and plan/assessment are information-gathering components that come later.

Chief Complaint and History of Present Illness

A health history starts with the patient's chief complaint, which is the reason they are presently seeking care. Asking about the history of present illness is how the nurse gathers additional context about the chief complaint to help the care team form a diagnosis and treatment plan.

Here's a common example: A 32-year-old patient comes to their primary care provider's (PCP's) office with a chief complaint of a sore throat. The nurse needs to get more details from the patient about the symptom to gather the information the provider will need to determine the cause of the patient's symptom. What possible explanations might the provider want to consider, and how can the health care team get the information necessary to solve the diagnostic puzzle? Is the patient experiencing a sore throat because they have strained or overused their voice? Do they have a viral illness? Is it related to a chronic condition?

The nurse needs to ask the patient questions like, "When did the sore throat start?" to establish a timeline of the problem. If the patient states that the pain began two days ago, the nurse can find what the patient was doing around that time that could have contributed to the pain. For example, if the patient visited a theme park the day before and rode roller coasters, screaming in excitement as they did, it's possible that the pain is from overuse or strain. But the nurse still needs to gather more information rather than making assumptions.

A patient who visited an amusement park would also have been spending time around others and could have been exposed to a virus. It's important to ask the patient whether they have any other signs or symptoms, like a fever or congestion, that could support the thought that their sore throat is from an illness. Asking about other signs and symptoms also provides information that helps differentiate between an infectious and noninfectious cause. A patient with a sore throat and congestion but no fever may have seasonal allergies, which could also be noted in their medical history. A patient with a fever and a sore throat may have a viral or bacterial infection, particularly if they report being around a sick person recently.

CLINICAL JUDGMENT MEASUREMENT MODEL

Recognize and Analyze Cues

Before a nurse can analyze cues to form a hypothesis, they must first make sure they have enough information about a patient's situation to correctly interpret the information and develop a plan of care. Suppose a patient claims to have an allergic reaction to all vaccines. The nurse will need to assess further. For example, the nurse will need to ask what symptoms the patient experienced to determine if the patient's reaction was truly an

allergen-induced response or a side effect of the vaccination. The patient may report an allergy to the flu vaccine by stating they experienced redness at the injection site after taking the flu shot last year. However, redness at the injection site is a common side effect of all vaccinations; it is not necessarily a sign of an allergy. Only after considering all relevant information should the nurse move on to the next step of the Clinical Judgment Measurement Model: prioritizing a hypothesis and providing the appropriate education to the patient.

(NCSBN, n.d.)

Past Health History

A patient's past health history includes any childhood illnesses, immunization record, current conditions, acute illnesses, accidents, injuries, and chronic illnesses, as well as any treatments. Even though these may not all be obviously relevant to the patient's chief complaint, they can provide the nurse with key insights.

Take the patient with a sore throat as an example. A patient with a fever and sore throat that began two days after a trip to an amusement park could have a common viral or bacterial infection like strep throat, the flu, a cold, or COVID-19. If the patient's past health history shows they were diagnosed with lupus several years ago, the nurse might consider that the excursion and ensuing exhaustion could have triggered a flare. What additional information does the provider need? Does the patient have a rash? Have they been taking their medications as prescribed?

Family History

When interviewing the patient, inquire about chronic conditions or diseases in the patient's immediate family, including parents and siblings, and ask about the health of their immediate family members, which primarily includes their parents and siblings. Do any of them have any chronic conditions? Are there any diseases or health risks that the patient may have a genetic predisposition to? While it may not seem immediately applicable to the patient's current problem, the information the nurse gathers here helps create a more complete picture of the patient's health.

Review of Systems

The ROS covers more of the physical health details of the patient's chief complaint. Each body system can offer clues about the patient's current problem, though the nurse will want to pay particular attention to those that are most relevant to the patient's present symptoms. For the patient with a fever and sore throat, the upper body systems—including the head, face, neck, and respiratory systems—may hold pertinent clues about the cause of the patient's throat pain. Whole-body, or **constitutional**, signs and symptoms, such as fever and fatigue, can also provide insight into the cause of the patient's pain.

The body systems covered in the problem pertinent ROS include (Vanderbilt University Medical Center, 2019):

- Constitutional: body-wide (e.g., fever, fatigue, weight loss)
- Head, eyes, ears, nose, and throat (HEENT)
- Respiratory
- Cardiovascular
- Gastrointestinal
- Genitourinary

There are also other system assessments that are part of an extended or more complete ROS:

- Metabolic/endocrine
- Neurological
- Psychiatric
- Integumentary
- Musculoskeletal
- Hematologic
- Immunologic

The nurse will document the findings of the ROS based on whether signs and symptoms are present in each system. The term **positive** is often used to note when a sign or symptom is present, while **negative** is used when signs and symptoms are absent from a system. In some provider documentation, the "+" may be used for positive and the "–"

sign for negative, with specific details pertaining to the problem within the body system. Other providers may use terms like "unremarkable" to denote an assessment that system assessment is normal.

Current Medications

When reviewing the patient's medical record, it's important to note that the medication list may or may not be up to date. It is essential that each time a patient is seen, they are asked about all medications, even OTC supplements or herbal remedies, that they are actually taking at home. If the patient has any prescribed medications, confirm the names, reasons for taking, dosages, and frequencies of each. Sometimes, patients will bring their medication bottles with them, which can be extremely helpful for medication reconciliation (AHRQ, 2019). It is also important to ascertain whether the patient has been taking medications as prescribed; in other words, it's not enough to simply ask *if* the patient is taking their medication but find out *how* they are taking it. When a patient reports they are no longer taking a specific medication (discontinued) or there has been a change in administration (e.g., increased or decreased dose), update their record. A precise and thorough medication reconciliation assists in preventing medical errors, which in turn decreases length of stay, lowers hospital costs, and reduces readmissions (Alghamdi et al., 2023).

Social Determinants of Health

There are also sociocultural factors about which the nurse needs to gather information to provide additional context about the patient's current health:

- Education
- Occupation
- Nutrition, diet, physical activity
- Financial status
- Environment (e.g., living, work)
- Lifestyle habits (e.g., tobacco, alcohol, substance use)
- Psychological well-being (e.g., stress)
- Spirituality
- Sexuality
- Cultural background

Including these factors ensures that the nurse has captured the details about a patient's life that could not only be relevant to their chief complaint but could affect the treatment decisions that will come after a diagnosis is made. This sociocultural history allows for more of a narrative about the person and not only the symptom that has brought them to see the provider. Here, the nurse can grasp more about who the patient is, what their life is like, and explore how the patient perceives and feels about their general health. The patient's social history is also an important opportunity to identify risk factors that could either be relevant to the patient's current problem or overall well-being. Table 6.3 compares protective factors with risk factors.

Protective Factors	Risk Factors
Strong social support network (e.g., family, friends, community)	Social isolation or lack of support
Stable employment and financial security	Unemployment or financial instability
Access to health care and health insurance	Lack of access to health care or inadequate insurance
Able to access and partake in health-promoting lifestyle habits (e.g., exercise, nutritious diet, sleep)	Sedentary lifestyle, lack of access to nutritious food, inadequate sleep
Positive coping mechanisms for stress	Negative coping mechanisms (e.g., substance misuse, isolation)

TABLE 6.3 Protective Factors versus Risk Factors in Patient Health

Protective Factors	Risk Factors
Engagement in meaningful activities and hobbies	Lack of purpose or meaningful engagement in life
Education and health literacy	Low literacy/health literacy
Safe and stable housing	Unstable housing or homelessness
No exposure to violence or trauma	Exposure to violence, abuse, or trauma
Spiritual or religious beliefs that provide comfort and support	Negative spiritual or religious beliefs/loss of faith, spiritual crises

TABLE 6.3 Protective Factors versus Risk Factors in Patient Health

6.4 Bedside Physical Assessment in Medical-Surgical Nursing

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Review the different parts of the bedside assessment
- Describe a focused physical assessment
- Discuss the importance of assessment of the safety and surroundings in medical-surgical nursing

While a **comprehensive physical assessment** is a detailed, inclusive assessment of body systems to provide a big-picture, broad view of a patient's overall health, a **focused assessment** is a physical examination centered on a patient's chief complaint. In this section, you will learn about the parts of a broader physical assessment—the bedside assessment—and how this more thorough approach differs from the focused assessment and contributes to the care of a hospitalized patient. The nurse may only focus on a single system during a focused assessment, but they can get an inclusive view of the patient's other systems during a bedside assessment. Not only does this help the nurse identify other potential areas of concern, but even normal findings will help establish a baseline for the patient. The comprehensive physical assessment, which includes all body systems along with the patient's history, gives the nurse a more complete picture of the patient's overall health situation and status. That, however, is often more valuable in primary care settings. In acute care settings, nurses mostly utilize bedside or focused assessments. Table 6.4 summarizes the types of assessments.

Assessment Type	Description	Components	Purpose
Focused Physical Assessment	Zeroes in on the patient's chief complaint, targeting the specific body system or area relevant to the presenting problem.	Varies depending on the chief complaint (e.g., cardiovascular assessment for chest pain, respiratory assessment for shortness of breath).	To timely identify and address the immediate concern or issue.
Bedside Physical Assessment	A systematic head-to-toe review of the patient's major body systems, often conducted upon admission or at the beginning of a shift.	General survey (height, weight, appearance), HEENT, cardiac, respiratory, abdominal, peripheral vascular, neuro-muscular, integumentary, genitourinary assessments.	To establish a baseline for the patient's condition and identify any potential issues that may require further investigation or intervention.

TABLE 6.4 Types of Assessments in Medical-Surgical Nursing

Assessment Type	Description	Components	Purpose
Comprehensive Physical Assessment	The most thorough assessment, encompassing all body systems, along with a detailed health history.	All body systems, plus a detailed history including past medical history, medications, allergies, family history, and lifestyle factors.	To provide a holistic view of the patient's health status and guide the development of a comprehensive care plan.
Safety/ Surroundings Assessment	Critical for preventing adverse patient outcomes, this assessment focuses on the patient's environment and potential risks.	Patient identification, fall risk, ambulatory aids, environmental hazards, domestic violence risk, suicidal ideation, isolation precautions, bed position, side rails, call bell accessibility.	To ensure a safe environment for the patient and prevent harm or injury.
Comprehensive Health History	A detailed interview with the patient to gather information about their past and current medical conditions, medications, allergies, family history, and lifestyle factors.	Medical history, surgical history, medication history, allergies, family history, social history (lifestyle, occupation, habits), review of systems.	To understand the patient's overall health status, identify risk factors, and tailor the care plan to their individual needs.

TABLE 6.4 **Types of Assessments in Medical-Surgical Nursing**

This section will also describe the importance of the safety/surroundings part of the assessment. This section will clarify how the comprehensive physical exam supports the comprehensive health assessment.

The Bedside Assessment of a Medical-Surgical Nurse

The nurse will perform a systematic exam of all patient body systems called a **bedside assessment**. This will include the general survey, HEENT, cardiac, respiratory, abdominal (gastrointestinal), peripheral vascular, neuromuscular, skin, genitourinary, and activity (Figure 6.5).

FIGURE 6.5 The wealth of information that the nurse can gather through physical exams can be organized and analyzed by using focused assessments for the body systems most related to the patient's current problem. (credit: "Combat nurses: The ER" by Tech. Sgt. D. Clare/ U.S. Air Force, Public Domain)

General Survey

The general survey assessment includes the patient's height, weight, physical appearance, chronic wounds, personal hygiene, and general behavior. Also included are the vital signs, such as blood pressure, heart rate, oxygen saturation levels, body temperature, and respiratory rate. The nurse will also consider the patient's verbal and nonverbal communication and must swiftly assess to determine if the patient needs a communication aid (such as a translation device). The nurse will appropriately document all findings in the physical assessment area of the patient's chart.

HEENT Assessment

In a systemic approach, the head, ears, eyes, nose, and throat (HEENT) exam are the first systems to be assessed.

- Head: The nurse will inspect and palpate the patient's head for abnormalities and look at the hair for obvious signs of illness (e.g., thinning, hair loss).
- Eyes: The nurse will inspect the eyes according to the eye assessment **PERRLA** (pupils equal, round, reactive to light and accommodation). They will also assess visual acuity (e.g., does the patient need glasses or contacts, when was their last eye exam), check for nystagmus, and confirm that the conjunctivae are clear.
- Ears: The nurse will inspect and document any hearing loss or difficulty, including whether the patient needs hearing aids. If so, the nurse should determine whether the patient is wearing their hearing aids or has the devices with them.
- Nose: The nurse will inspect and ask about any olfactory symptoms, including altered sense of smell, congestion, or irritation. The nurse will ask if the patient has had any surgeries or procedures on the nasal area.
- Throat: The nurse will inspect and document any signs or symptoms related to the mouth and throat. This includes assessing the gums, teeth, mucosa, tongue (e.g., appearance and deviation), pharynx, and tonsils.

Cardiac Assessment

The cardiac assessment requires inspection, palpation, and auscultation. This includes assessing cardiac rhythm, heart sounds, arterial pulse evaluation, capillary refill times, edema, circulation and sensation, and cyanosis.

Respiratory Assessment

The respiratory assessment involves inspection, palpation, auscultation, and percussion. This includes breath

sounds, respirations (e.g., effort and quality), presence of cough, production of sputum/secretions, abnormal visual/palpable masses, current respiratory treatment, and oxygen delivery.

READ THE ELECTRONIC HEALTH RECORD

Assessment of a Patient with Abdominal Pain

Patient Information
Name: Tanecia Smith
Age: 37 years
Sex: Female

Chief complaint:

- Severe abdominal pain, primarily in the upper right quadrant, for the past 3 days

Medical history:

- Diagnosed with hyperlipidemia 3 years ago
- History of vaginal delivery to a set of healthy twin boys 12 weeks ago
- Previous episodes of mild spasms related to gallstones, treated successfully with antispasmodics and diet change

Vital signs:

- Temperature: 89.3°F (38.5°C)
- Heart rate: 125 bpm
- Blood pressure: 140/90 mm Hg
- Respiratory rate: 26 breaths per minute
- Oxygen saturation: 99% on room air
- BMI: 38

Recent laboratory results:

- WBC count: 14,000/µL (elevated)
- Hemoglobin: 13.5 g/dL (normal)
- Hematocrit: 40.5% (normal)
- Platelets: 250,000/µL (normal)
- Amylase: 180 U/L (elevated)
- Lipase: 166 U/L (elevated)

Electrolytes:

- Sodium: 138 mmol/L (normal)
- Potassium: 4.0 mmol/L (normal)
- Chloride: 102 mmol/L (normal)

Imaging Results

- CT scan of abdomen and pelvis: Findings consistent with acute cholecystitis; presence of inflamed gallbladder, blockage of the biliary duct to the pancreas; no abscess or free air noted

Progress notes:

- Patient reports increased severity of abdominal pain and tenderness over the past 3 days after ingesting some pizza.
- Appetite has decreased, and she has experienced nausea after drinking even water.
- Vomiting noted today resembling biliary juices; steatorrhea noted.
- Patient has been compliant with reduced-fat diet until 3 days ago.
- Mild diaphoresis observed upon admission.

Current medications:

- Acetaminophen 500 mg every 6 hours as needed for pain
- Dicycloverine 10 mg up to three times a day to relieve spasms

1. What information in the patient's chart concerns you?
2. What information is the most concerning?
3. What is an expected finding?
4. What information should you question?

Abdominal Assessment

The abdominal assessment also relies on inspection, palpation, auscultation, and percussion. The nurse will assess the abdominal appearance, bowel sounds, and stool. The nurse will also inquire about the patient's nutrition (e.g., current diet) and appetite.

Peripheral Vascular Assessment

The peripheral vascular assessment uses inspection, palpation, and auscultation. This includes pain, pallor of skin, inability to regulate core temperature (**poikilothermia**), pulselessness, paresthesia, and paralysis.

Neuro-muscular Assessment

The neuro-muscular assessment relies on inspection. It includes orientation (e.g., person, place, and time), level of consciousness, Glasgow Coma Scale (GSC), speech assessment, gait assessment, movement and strength of extremities (e.g., equal or unequal), and pain.

Skin Assessment

The skin assessment uses inspection and palpation. This includes turgor, integrity, color, temperature, Braden Risk Assessment to assess for pressure sore risk, chronic wounds, and skin breakdown.

Genitourinary Assessment

The genitourinary assessment involves inspection of the urinary and reproductive system. This includes the character of voiding and discharge, urinary difficulty, or presence of a catheter. It also includes specific reproductive health concerns, such as menstrual/menopause, vaginal bleeding, and painful intercourse.

LINK TO LEARNING

Watch this video to see an example of a head-to-toe physical assessment (https://openstax.org/r/77Physical) at the patient's bedside.

The Focused Assessment of a Medical-Surgical Nurse

The focused assessment, like a focused history, starts with the patient's chief complaint. The nurse will center the physical examination on the reason the patient is seeking care at the present time. For example, the focus for a patient who presents with a sore throat will be head/eye/ear/nose/throat (HEENT). By focusing the exam on the patient's problem, the nurse will efficiently retrieve information that will help the health care team make the correct diagnosis and, if needed, appropriate plan of treatment.

Safety and Surroundings Assessment

The safety and surroundings assessment is critical to preventing adverse patient outcomes. It involves confirming the patient's identity through wrist band identification, and assessing fall risk, use of ambulatory aids, environmental concerns, domestic and family violence risk, and suicidal ideation. The safety and surroundings assessment helps the nurse avoid preventable errors, such as patient misidentification, allergic reactions, and falls or other injuries. It is also a method to guard against safety threats the health care professionals may face (for example, if a patient has an infectious disease or is violent). The patient safety assessment during hospitalization may include documenting:

- Patient activity
- Intravenous insertion sites, drains, pumps
- Oxygen delivery system

- Allergy wristband
- Isolation precautions
- Family in the room
- Bed position, side rails up
- Call bell within reach

CLINICAL SAFETY AND PROCEDURES (QSEN)

QSEN Competency: Informatics

Disclaimer: Always follow the agency's policy for medication administration.

Definition: Follow effective strategies to reduce human error when providing patient care. Examples include using allergy ID bands and checking that the bed is in the lowest setting.

Knowledge: The nurse will identify essential information that must be available in a common database to support patient care. Examples include staying up to date with current signs and symptoms of medication reactions.

Skill: Use clear and concise communication to raise awareness of observed concerns. Examples include contacting the provider if the patient exhibits signs of being a fall risk or has a potential medication reaction.

Attitude: The nurse will value national safety campaigns by implementing current safety initiatives into everyday practice guidelines. Examples include implementing safety checks and rounding on patients every thirty minutes.

(QSEN Institute, n.d.)

Summary

6.1 Critical Thinking in Assessment

- Nurses must develop critical thinking skills to gather and analyze patient data. These skills lay the foundation for clinical judgment, which underlies the nursing process.
- Clinical judgment allows nurses to synthesize their knowledge, experience, and intuition with the available data to make informed, evidence-based decisions about patient care.
- As nurses develop their critical thinking and clinical judgment skills, they will become more adept at evaluating their own process and recognizing areas in need of improvement.
- One of the key models used in nursing today is the Clinical Judgment Measurement Model (CJMM), which guides nurses as they develop critical thinking and clinical judgment skills.

6.2 Effective Communication in the Nurse-Patient Relationship

1. It is the nurse's responsibility to establish and maintain a trusting therapeutic relationship with each patient in their care.
2. The nurse-patient relationship is unique and complex, and the nurse will draw on their critical thinking and communication skills to develop and maintain it.
3. The nurse must establish professional boundaries, striking a balance between being empathetic and avoiding becoming too personal.
4. Both verbal and nonverbal communication are part of interactions with patients as well as colleagues.
5. In the clinical setting, the nurse must be aware of the resources and tools available to them to facilitate communication with patients based on needs, as well as strategies to enhance communication with other providers about patient care.
6. The nurse must understand how different models of communication are used and adjust their communication according to the situation.

6.3 Health History

- The comprehensive health history is a higher-level and more comprehensive view of a patient's overall health.
- The focused health history centers on the chief complaint that prompted the patient to seek care at the present time.
- When obtaining a complete/comprehensive health history, the nurse will systematically follow a structured format to ensure that all components have been covered.
- The chief complaint, history of present illness, past health history, family history, review of systems, current medications, and sociocultural factors all come together to help the care team form a diagnosis and plan for treatment.

6.4 Bedside Physical Assessment in Medical-Surgical Nursing

- A complete physical examination provides a top-level, thorough view of a patient's health. It is more comprehensive and inclusive than other assessments and provides an overall view of the patient's health.
- At each step in the assessment and examination process, the nurse must accurately document their findings so that the information can be efficiently and effectively communicated to the care team.
- The bedside comprehensive physical examination includes the following nursing assessments: general survey, HEENT, cardiac, respiratory, abdominal (gastrointestinal), peripheral vascular, neuro-muscular, skin, genitourinary, and activity.
- When a patient seeks care for a specific problem, the nurse will start with a focused assessment in which they will gather more information on the chief complaint.
- While the safety and surroundings assessment pertains to the patient's safety in the facility, the nurse must also assess the patient's home safety. The details of the assessment can also be important for the safety of the nurse and other staff.

Key Terms

bedside assessment systematic exam of all patient body systems
body language type of nonverbal communication based on physical movement and expression

chief complaint reason the patient is currently seeking care
comprehensive physical assessment detailed, inclusive assessment of body systems to provide a big-picture, broad view of a patient's overall health
constitutional relating to the whole body
focused assessment physical examination centered on a patient's chief complaint
intuition "sixth-sense" of knowing that largely comes from years of education and problem-solving in real-world patient situations
medication reconciliation process of reviewing a patient's medications listed in their medical record and comparing that list to what the patient is actually currently taking at home
negative used to note when signs or symptoms in a system are absent
nonverbal communication physical movements or motions, including body language, that convey thoughts, attitudes, and sentiments
patient-centered decisions made with respect for the patient's interests, needs, culture, values, and preferences
PERRLA eye assessment that determines if pupils are equal, round, reactive to light and accommodation
poikilothermia inability to regulate core temperature
positive used to note when signs or symptoms in a system are present
professional boundary clear separation between personal and work life when interacting with patients
verbal communication spoken word, in whatever language the patient can best communicate and understand
visual communication strategies like return demonstration that can confirm a patient's understanding
written communication reinforcement of verbal information given to the patient in a format they can read

Assessments

Review Questions

1. What is a definition of critical thinking skills in nursing?
   a. Habitually using a set of rational standards to guide informed decision-making.
   b. Taking action after considering all the available patient data.
   c. Feelings based on a combination of experience, emotional intelligence, and mental reasoning.
   d. Seeking feedback on personal performance and evaluating patient outcomes.

2. The nurse is gathering a history from a patient who presents to the ER with a severe headache. What is an action by the nurse that demonstrates the importance of critical thinking?
   a. The nurse asks the patient about what medications they are currently taking instead of checking the patient's chart.
   b. The nurse notes the patient's current medication list in the chart and does not ask them what medications they currently take to save time so they can prioritize a focused physical assessment.
   c. The nurse asks the patient what medications they currently take at home and compares them to the information listed in the patient's chart, noting there are discrepancies.
   d. The nurse does not ask the patient about current medications because assessing their pain level needs to be the priority.

3. In what way does critical thinking connect to clinical judgment?
   a. Critical thinking is part of clinical judgment but is a narrower set of skills.
   b. Clinical judgment must be the foundation for critical thinking.
   c. Clinical judgment stems from intuition, while critical thinking is not based on experience.
   d. Critical thinking and clinical judgment refer to the same set of nursing skills, and the terms can be used interchangeably.

4. A nurse working in a busy medical surgical unit has just received a new patient. They walk into the patient's room to start the comprehensive history and physical assessment. They notice that the patient is sitting on the stretcher, arms crossed, and frowning. What form of communication is this patient exhibiting?
   a. Verbal
   b. Welcoming

c. Nonverbal
d. Written

5. The nurse is caring for a patient who does not speak English. The patient's daughter offers to translate. What is the appropriate action for the nurse to take?
a. Allow the patient's daughter to translate the conversation.
b. Use a phone app to translate what needs to be communicated to the patient.
c. Follow the facility's guidelines for acquiring assistive technology or an interpreter.
d. Explain to the patient's daughter that all communication will need to be in writing.

6. What is the last component of the ISBAR method of communication?
a. Recommendation
b. Revision
c. Review
d. Restatement

7. The nurse is preparing to complete a comprehensive health history and physical assessment on a new admission from the emergency department. The patient is a 35-year-old female with a chief complaint of shortness of breath. What description correctly demonstrates how the nurse will start the assessment?
a. The nurse starts the focused health history with questions about the patient's broken foot that occurred 1 year ago.
b. The nurse starts the focused health history with questions about the patient's menstrual cycle patterns.
c. The nurse starts the focused health history with questions about the patient's last asthma attack.
d. The nurse starts the focused health history with questions about the patient's shortness of breath.

8. In what section of the history would the nurse document that the patient denies alcohol, tobacco, and drug use?
a. Medical
b. Social determinants of health
c. Family
d. Current medications

9. The nurse is taking a history on a 65-year-old patient with diabetes who is at the provider's office for follow-up to discuss their most recent labs. The patient mentions their vision has "been blurry lately." What step would the nurse take based on this cue?
a. Tell the patient that they may need to see an eye doctor.
b. Make a note for the provider to do a vision test.
c. Change the focus of the assessment to check the patient's eyes.
d. Reassure the patient the symptom is probably age-related.

10. The nurse is taking care of a patient who is admitted to the hospital for a chief complaint of chest pain. What is a description that demonstrates how the nurse would proceed with a physical examination?
a. Start with the head-to-toe approach, head, eyes, ears, nose, and throat.
b. Start by letting the patient care technician change the patient's sheets, since the patient complained that they like new sheets right away.
c. Start with the cardiac system, then continue the bedside physical examination.
d. Start with the respiratory system, then continue the comprehensive physical examination.

11. What are the components of the HEENT assessment?
a. Head, eyes, ears, nose, thorax
b. Head, eyes, ears, nose, throat
c. Head, eyes, ears, nose, trachea
d. Head, eye, ears, nose, taste

Check Your Understanding Questions

1. Describe how you could use the CJMM to better understand your critical thinking skills.
2. Describe how your critical thinking skills will lay the groundwork for the development of your clinical judgment as a nurse.
3. What questions would you use when doing a focused health history of a patient with a chief complaint of abdominal pain?
4. You are a nurse in a busy med/surg unit. You are about to start your admission database with your new patient admitted from the emergency department. Your patient is a 55-year-old male admitted for chest pain. Your questions will initially focus on the chief complaint, but then what types of other questions will you ask him?
5. Describe the assessment approach you would use for a patient who presents with dizziness and balance problems.

Reflection Questions

1. Explain how the nurse can use critical thinking skills to identify patient factors that could affect information gathering during the assessment.
2. Describe how the nurse would move through the steps of the CJMM when caring for a patient with dementia who is not able to provide a reliable history.
3. You are caring for an 81-year-old patient in the ER. When you come into the room and introduce yourself, the patient smiles but does not verbally acknowledge you. As you start to ask questions, you notice that the patient is turning their head to the side and leaning slightly toward you. You check the patient's chart and note that they were fitted for hearing aids six months ago, but they do not appear to be wearing them, and you don't see them in the room. Describe what steps you would take to assess the patient's needs.
4. You are about to start a comprehensive history and physical assessment on a new patient who has just arrived in your unit. You received your ISBAR report, and the nurse told you that the patient does not speak English. The patient has a spouse with them who speaks English. How would you begin your assessment?
5. Explain why medication reconciliation is an important component of the patient's history, regardless of their chief complaint.
6. The family member of a patient who is paralyzed after a stroke expresses concerns about caring for them at home. What would you specifically want to cover in the assessment to mitigate risks for the patient at home?

What Should the Nurse Do?

1. You have completed a comprehensive physical and history assessment on a young patient with whom you have developed a good rapport. You are leaving at the end of your shift and say goodbye. The patient asks you if you will be their nurse tomorrow. You answer honestly that you never know what your assignment will be the day before. The patient states that they would like to request you as their nurse so they can get to know you better, and asks if the two of you could have coffee in the cafeteria tomorrow. If you were the nurse, what would you do?
2. A nurse in a busy ER enters the room of a patient who presents with a broken wrist. The patient is in pain and becomes impatient as the nurse begins to ask questions. How should the nurse respond when the patient asks, "Can't you just look this all up in my medical record?"
3. An 88-year-old patient on the med-surg unit fell in their room after trying to get from bed to the bathroom without assistance. What safety and surroundings assessment components related to the patient's home environment could have helped prevent this incident?

Competency-Based Assessments

1. Research the National Council of State Boards of Nursing (NCSBN)'s CJMM. What are some similar

frameworks that are also used in nursing?

2. Create a comparison table or chart that shows how nurses use critical thinking and clinical judgment. Think about how the skills differ as well as when they may overlap.
3. Practice applying TeamSTEPPS to the following clinical scenario: A 72-year-old patient is brought to the ER via ambulance with signs and symptoms of sepsis, including a high fever, rapid respirations, and hypotension. He was found unresponsive at home by his wife, who states he has been sick with "a UTI" for the last week.
4. Develop a clinical example of using ISBAR to communicate patient information to providers who are part of the care team.
5. Compare the components of a comprehensive ROS versus the focused ROS you may complete on a patient complaining of shortness of breath.
6. A 21-year-old patient at the local university presents to the campus health clinic. List the components of the patient's social history you would ask the patient about.

CHAPTER 7

Pain Assessment and Management

FIGURE 7.1 A patient in pain using a nonpharmacological method. (credit: modification of "Best Pillows for Shoulder Pain" by "samuelemunemu32"/flickr, Public Domain)

CHAPTER OUTLINE

INTRODUCTION Pain is subjective to the individual and may be characterized in many ways. Regardless, most people will experience it at some point in their life. The assessment and management of pain is a top priority for the nurse in providing comprehensive patient care. By conducting a pain assessment, the nurse can gain an understanding of the patient's subjective description of pain, including the severity of symptoms. Using the results from the assessment, the nurse can then implement both pharmacological and nonpharmacological interventions to manage the pain. Collaboration with the health care team is critical for achieving the best possible plan of care to relieve pain. This means the patient should be an active participant in the treatment plan, including establishing reasonable goals for managing pain.

7.1 Concepts and Causes of Pain

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define pain and its causes
- Differentiate among types of pain

Pain is an important communication tool that bodies use to indicate that something is wrong. Although everyone experiences pain, the perception of pain is unique and varies from person to person. "Pain is whatever the experiencing person says it is, existing whenever they say it does" (McCaffery, 1968). Pain may be classified

according to a variety of factors, such as location, onset, duration, and cause. Being able to differentiate between the types and characteristics of pain is a crucial skill when assessing pain.

What Is Pain?

Generally, **pain** is an uncomfortable or unpleasant sensation that typically signifies injury or illness. The purpose of pain is to tell the individual that something is not right within their body and requires further attention. For example, if a person touches a hot stove, they feel a burning sensation (pain) on the skin that tells them to stop touching the stove. If a person's knee hurts when walking after a fall, their body is telling them not to put weight on that knee.

Pain is a physiological process caused by interaction with nociceptors. A **nociceptor** is a type of sensory receptor that responds to potentially damaging stimuli by sending nerve signals to the spinal cord and brain in a process called nociception. There are several types and functions of nociceptors:

- Thermal nociceptors are activated by noxious heat or cold, such as a hot pan.
- Mechanical nociceptors are activated by excess pressure or mechanical deformation, such as a finger getting caught in a car door. They also respond to incisions that break the skin surface.
- Chemical nociceptors are activated by a wide variety of spices commonly used in cooking. For example, capsaicin is a compound in chili peppers that causes a burning sensation of the mucous membranes. It is also used in common over-the-counter creams for pain relief because when it is applied to the skin, it blocks the transmission of pain impulses.

Nociceptors detect noxious stimuli and transduce them into electrical energy. An action potential is created and transmitted along nociceptor fibers. There are two types of nociceptor fibers, A-Delta and C (Kendroud et al., 2022). A-Delta fibers are fast-conducting fibers associated with the initial sensation of sharp, stinging, or pricking pain. C fibers are slower-conducting fibers associated with the secondary sensation of diffuse, dull, burning, or aching pain. The pain impulse is transmitted along these nociceptor fibers to the dorsal horn in the spinal cord, and then from the spinal cord to the thalamus, where pain messages are relayed to the cerebral cortex. The cerebral cortex perceives pain impulses, so it is then that the person has conscious awareness of pain. Figure 7.2 illustrates this process.

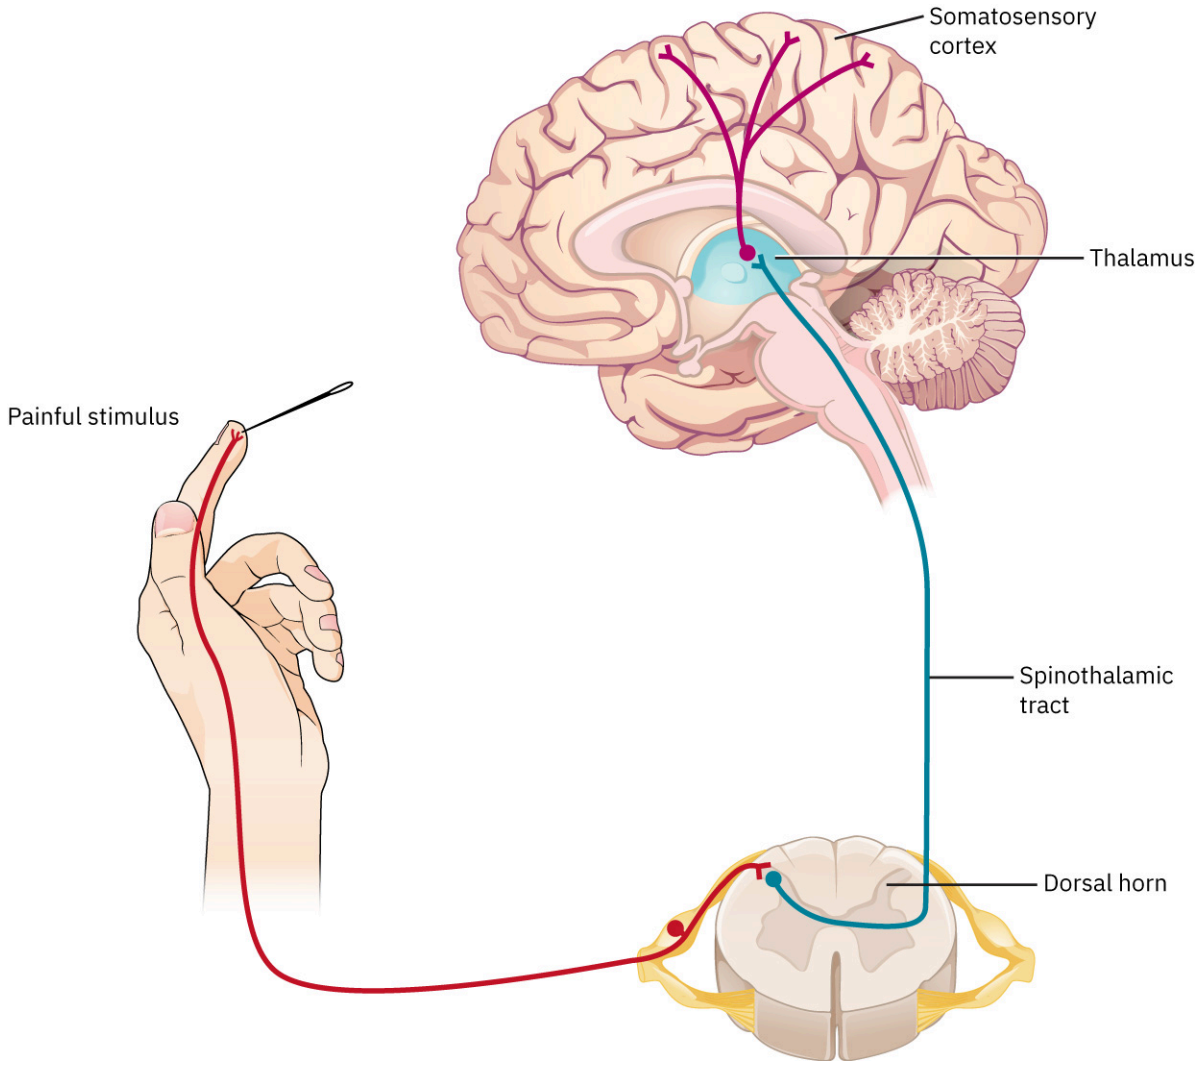

FIGURE 7.2 Through nociception, a noxious stimulus, or pain signal, is transmitted from the nociceptors to the spinal cord and then to the brain. (credit: modification of work from *Psychology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Types of Pain and Their Causes

Pain can be a normal response to an illness or injury and may not require medical treatment. This type of pain may be referred to as **normal pain**, which is of the severity and duration that you would expect to experience according to the cause of the pain. Examples of normal pain may be a skinned knee, minor burn, pulled muscle, or tension headache, or even more severe such as the pain of a sprained ankle, broken bone, labor and delivery, or recovery from surgery. Although medical treatment may be necessary to treat the underlying problem, the associated pain typically does not warrant further medical treatment. On the contrary, **abnormal pain** moves beyond the expected severity and duration expected from the cause of the pain and may require additional medical treatment. Examples of abnormal pain may be fibromyalgia, neuropathic pain, chronic back pain, and migraines, which are complex pain conditions characterized by chronic pain with varying intensity.

There are several different types of pain, each with its own indications for treatment and management. Pain may be characterized according to onset and duration, such as acute, chronic, or breakthrough. Pain may also be categorized as neuropathic or nociceptive, according to the type of damage that causes it. The types of pain are not isolated; sources of pain may fall into more than one of these categories. It is important to identify the type of pain in order to develop an individualized plan of care to treat and manage it.

Acute Pain

When pain is short in duration, typically lasting from minutes up to three to six months (depending upon the reference source), it is considered **acute pain**. It comes on suddenly and tends to be associated with a specific soft-

tissue injury, such an ankle sprain, or a temporary illness, such as gastritis. This type of pain may be sharp, throbbing, burning, stabbing, or tingling; it may manifest as weakness or numbness. Acute pain typically produces a physiological response resulting in vital sign changes, such as increased pulse, respirations, and blood pressure. Generally, once the injury heals or illness subsides, the pain subsides as well. Examples of acute pain include pain that results from surgery, cuts, burns, labor and delivery, and broken bones.

Nurses can identify acute pain by assessing the symptoms, intensity, and location of the pain, as well as the associated injury or illness. Blood tests, x-rays, computed tomography (CT scans), magnetic resonance imaging (MRIs), ultrasounds, dye-injection studies, and nerve conduction studies may also be helpful for diagnostic testing. Acute pain may be treated with rest, heat or ice, anti-inflammatory medications, physical therapy, exercise, stress reduction, bioelectric therapy (electrical impulses used to stimulate nerves and muscles), muscle relaxants, and short-term use of narcotics (International Association for the Study of Pain, 2021).

Do not ignore acute pain. If left untreated, acute pain may turn into chronic pain. For example, a broken bone that is left untreated may result in the bone not healing, leading to worsening pain over time. Acute pain may also turn into chronic pain when repeated or continuous nerve stimulation alters the pain pathways in the central nervous system. For example, repetitive knee injuries may result in subsequent arthritis over time.

Chronic Pain

By contrast, **chronic pain** is longer in duration, typically identified as pain lasting longer than six months. It often results from health conditions, such as arthritis, fibromyalgia, cancer, diabetes, and musculoskeletal deformities. Other causes of chronic pain include normal aging, wear and tear on bones and joints, nerve damage, and injuries that fail to heal properly. Chronic pain does not typically result in vital sign changes because the body has adjusted to the new normal of chronic pain.

Chronic pain may be categorized as constant or intermittent. Constant pain is continuous, though the intensity of the pain may vary at times. Back injuries, for instance, may result in chronic pain; the pain may worsen or lessen with certain movements, but it is constant. Intermittent pain comes and goes. Migraines, for example, may be considered chronic pain if the person has experienced them over a time period longer than three months; the migraines themselves come and go, however, so they are considered intermittent.

Chronic pain may alter in severity, depending on the day. Some days the pain may be mild or nonexistent, and other days the pain may be severe and debilitating. Due to its chronic nature, this pain may considerably affect the quality of one's life. It can have physical effects, such as tense muscles, limited mobility, a lack of energy, and changes in appetite. It may also cause emotional effects, such as depression, anger, anxiety, and fear of reinjury. When managing chronic pain, it is important to assess one's ability to perform activities of daily living, as well as assess for signs of depression and anxiety. Early intervention is key to preserving quality of life and mental well-being.

Breakthrough Pain

A sudden increase in pain that lasts for a short time is called **breakthrough pain**. It may be caused by stress, illness, or activity, by the wearing off of pain medicine, or for no known reason. Breakthrough pain may occur with acute or chronic pain. Acute surgical pain, for instance, may be well controlled with oral analgesics, but the patient may experience a sudden increase in pain after physical therapy exercises that result in the need for additional doses of pain medications between the regular doses of oral analgesics. In contrast, a patient diagnosed with rheumatoid arthritis may experience chronic pain that is well controlled with the patient's regular pain medication regimen; a flare-up of pain may require additional therapeutic medications to be added to the regimen until the breakthrough pain subsides.

Neuropathic Pain

Damage to nerves or other parts of the nervous system can result in **neuropathic pain**. It may be characterized as shooting, stabbing, sharp, or burning pain. Some people may even describe the pain as an electrical shock or say it feels like "pins and needles." Common causes of neuropathic pain include cancer, stroke, limb amputation, radiation, chemotherapy, and diabetes.

Neuropathic pain is a type of chronic pain that can be so severe that it becomes debilitating. It may interfere with the ability to perform everyday tasks and be severe even with normal movement. As a result, the person may experience mobility issues. Neuropathic pain may also affect sensitivity: for example, it can interfere with a person's

ability to feel hot and cold sensations, which may result in injury. The person may touch a hot pan, not be able to sense that it is hot, and end up with severe burns to their fingers.

Following an amputation, patients may experience a type of neuropathic pain known as **phantom pain** in which the patient perceives the pain to be coming from the missing body part. Approximately 80 percent of patients who undergo an amputation will experience phantom pain (Cleveland Clinic, 2021). Phantom pain is caused by the brain misinterpreting the pain signals, but the pain is real. It may last for seconds, hours, days, or longer, and may be described as burning, aching, pinching, itching, tingling, shooting, stabbing, throbbing, or twisting. Diagnose phantom pain by conducting a physical exam and ruling out other medical causes, such as infections.

Nociceptive Pain

Pain caused by damage to the body tissue, typically from injury to joints, muscles, skin, tendons, or bones, is called **nociceptive pain**. It is often described as sharp, achy, or throbbing. Nociceptive pain may be either acute or chronic. For example, a scrape to the knee, a twisted ankle, or a blow to the head may be characterized as acute nociceptive pain. If the blow to the head were to result in subsequent migraines lasting longer than three months, it would then be characterized as chronic nociceptive pain.

There are two types of nociceptive pain. The first, **somatic pain**, is experienced in the muscles, skin, or bone. This pain is focused on a specific area of the body and is typically more intense than visceral pain. It is often characterized as cramping, aching, or gnawing. Examples include pain resulting from headaches, the motion of injured limbs, or cuts in the skin. The other type of pain, **visceral pain**, is experienced in the internal organs; the exact location may be difficult to identify. Visceral pain is oftentimes described as aching, cramping, or as pressure in the body. Examples include pain caused by endometriosis, bladder infection, and irritable bowel syndrome. (Table 7.1) displays the defining characteristics of nociceptive and neuropathic pain.

Nociceptive Pain		Neuropathic Pain
Somatic Pain	**Visceral Pain**	
Arises from the muscles, skin, or bone	Arises from the internal organs	Arises from damage to the nervous system
Characterized as cramping, aching, gnawing	Characterized as achy, pressure, cramping	Characterized as shooting, stabbing, sharp, burning, electric-like sensation, “pins and needles”
Examples: infection, postoperative, fracture	Examples: endometriosis, irritable bowel syndrome, pancreatitis	Examples: neuropathy, phantom limb pain, shingles

TABLE 7.1 Defining Characteristics of Nociceptive and Neuropathic Pain

Referred Pain

When the pain in one part of the body is caused by pain in a different location in the body, it is considered referred pain. Referred pain can happen if the brain incidentally sends a pain signal to a different part of the body. Although **referred pain** may be felt anywhere, areas such as the shoulders, neck, back, teeth, and jaws are common sites of referred pain. Referred pain is typically the result of an overlapping dermatome, specific regions of the skin that connect to a single spinal nerve root. Due to the shared neural pathways, the individual may feel the pain in a different portion of the dermatome supplied by the same nerve root. For example, a person having a heart attack may experience shoulder pain, whereas pain in the lower back may be caused by kidney pain.

7.2 Pain Assessment

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss key elements of assessing a patient's pain
- Relate principles of pain assessment to pain reassessment after evaluation

According to the American Pain Society, pain is the fifth vital sign (Department of Veterans Affairs, 2000). Just as blood pressure, heart rate, respirations, and temperature inform the nurse of the patient's condition, so does pain. Pain assessments should be performed routinely to allow for better pain management by developing a treatment plan that meets the individual needs of the patient.

Performing a Pain Assessment

Perform pain assessments on a regular basis, before and after procedures, during routine checkups, and when a patient reports pain. Prior to administering pain medication, nurses must perform a thorough pain assessment. They must then reassess the pain at least fifteen minutes after administering the medication to evaluate effectiveness. Conducting a pain assessment is a multifactorial process that involves gathering several different sources of information. A thorough pain assessment identifies the patient's risks for pain, assesses the pain using an approved pain scale, determines the classification of pain (nociceptive, neuropathic, referred, somatic, visceral, phantom), determines if the pain is acute or chronic, and assesses the patient's previous response to pharmacological interventions and analgesics, noting any adverse reactions. During a pain assessment, the patient should also be assessed for physical, behavioral, and emotional signs of pain, such as confusion, diaphoresis, moaning, decreased activity, irritability, guarding, grimacing, clenched teeth, muscle tension, depression, and insomnia. These cues are important because they may not align with the results obtained by a pain screening tool. By combining several different ways of assessing pain, the nurse can better understand and manage a patient's pain experience and determine next steps when discrepancies in pain assessments arise.

CULTURAL CONTEXT

Cultural Perspectives of Pain

Culture is directly related to the physical and emotional expression of pain. Some cultures, such as those based in east Asia, place great value on self-discipline and control. Persons with these backgrounds may be more stoic, choosing to bear their pain and withdraw socially rather than express their discomfort. Even when experiencing severe pain, their facial expression may be neutral. Other cultures, such as those with Middle Eastern or Mediterranean roots, may place greater value in the expression of pain; people with these backgrounds may want others around them when they are in pain (Givler et al., 2023). Additionally, there are myths associated with certain cultures an pain. For example, studies have shown that providers are less likely to provide pain medication for Black patients (Sabin, 2020).

Despite these examples, it is important not to generalize about someone's pain based upon their culture alone. Instead, nurses must understand how a patient's culture may affect pain and use this information to create an individualized plan to best meet their individual needs.

Mnemonics for Assessment

Nurses often use mnemonics to remember standardized questions for conducting a comprehensive pain assessment. Although there may be a variety of mnemonics in use, three of the most common mnemonics are:

- COLDSPA
- OLDCARTES
- PQRSTU

The letters in each mnemonic stand for important categories of information relevant to a patient's pain experience. Nurses may ask any number of questions to obtain information for each category. Table 7.2 lists questions that can be used to assess pain using the COLDSPA mnemonic.

COLDSPA	Questions to Ask
C: Character	What does the pain feel like? Does it feel like burning, stabbing, aching, dull, throbbing, etc.?
O: Onset	When did the pain start? What were you doing when the pain started?
L: Location	Where do you feel the pain? Does it move around or radiate elsewhere? Can you point to where it hurts?
D: Duration	How long has the pain lasted? Is the pain constant or does it come and go? If the pain is intermittent, when does it occur?
S: Severity	How would you rate your pain on a scale of 0 to 10, with 0 being no pain and 10 being the worst pain you've ever experienced? How much does it bother you?
P: Pattern	What makes your pain feel better? What makes your pain worse? Does the pain increase with movement, certain positions, activity, or eating?
A: Associated factors	What do you think is causing the pain? What other symptoms occur with the pain? How does the pain affect you?

TABLE 7.2 COLDSPA Assessment

The OLDCARTES mnemonic consists of similar categories as well as specific prompts related to pain treatment. Table 7.3 lists questions that can be used to assess pain using the OLDCARTES mnemonic.

OLDCARTES	Questions to Ask
O: Onset	When did the pain start? Can you recall any specific incident or event that caused the pain to begin?
L: Location	Where is the pain located? Can you point to where it hurts?
D: Duration	How long has the pain been bothering you? Is the pain continuous, or does it come and go?
C: Character	What does the pain feel like? Does it feel like burning, stabbing, aching, dull, throbbing, etc.?
A: Aggravating factors	What makes the pain worse? Are there any activities, movements, or conditions that make the pain worse?
R: Radiating	Does the pain travel to other parts of your body? Can you describe where the pain spreads to?

TABLE 7.3 OLDCARTES Assessment

OLDCARTES	Questions to Ask
T: Treatment	What has been done to make the pain better and has it been helpful?
E: Effect	How does the pain affect your daily activities and quality of life?
S: Severity	On a scale from 0 to 10, with 0 being no pain and 10 being the worst pain imaginable, how would you rate your pain?

TABLE 7.3 OLDCARTES Assessment

The PQRSTU mnemonic uses fewer letters by combining several categories. Table 7.4 lists questions that can be used to assess pain using the PQRSTU mnemonic.

PQRSTU	Questions to Ask
P: Provocation/ Palliation	What makes your pain worse? What makes your pain feel better?
Q: Quality	What does the pain feel like? Note: You can provide suggestions for pain characteristics such as “aching,” “stabbing,” or “burning.”
R: Region/ Radiation	Where exactly do you feel the pain? Does it move around or radiate elsewhere? Can you point to where it hurts?
S: Severity	How would you rate your pain on a scale of 0 to 10, with 0 being no pain and 10 being the worst pain you’ve ever experienced?
T: Timing/ Treatment	When did the pain start? What were you doing when the pain started? Is the pain constant or does it come and go? If the pain is intermittent, when does it occur? How long does the pain last? Have you taken anything to help relieve the pain?
U: Understanding	What do you think is causing the pain?

TABLE 7.4 PQRSTU Assessment

Regardless of the pain assessment framework used, it is important to use open-ended questions that allow the patient to describe the pain in their own words. Closed-ended questions result in “yes” or “no” responses and fail to capture a comprehensive description of the pain. It is also important to follow up on the patient’s initial responses by asking clarifying questions and to continue asking questions until you have a clear enough understanding of the pain to develop and implement an individualized pain treatment plan. In doing so, the nurse should collaborate with the patient to establish reasonable pain goals that are fluid over time and reflective of the patient’s current condition.

Pain Is Subjective

Given that pain is invisible and everyone’s body is different, every person’s response to pain will be different. Even with the same stimuli, the perception of pain will vary from person to person and cannot be generalized across persons. For example, some patients may experience severe pain when receiving injections, whereas others may feel no pain at all. Consequently, nurses must consider pain to be whatever the patient says it is. Table 7.5 displays

the biological, psychological, and social factors that affect the perception of pain. Nurses must consider these factors when assessing and treating pain.

Category	Factors
Biological	• Nociception • Brain function • Source of pain • Illness • Medical diagnosis • Age • Injury, past or present • Genetic sensitivity • Hormones • Inflammation • Obesity • Cognitive function
Psychological	• Mood/affect • Fatigue • Stress • Coping • Trauma • Sleep • Fear • Anxiety • Developmental stage • Meaning of pain • Memory • Attitude • Beliefs • Emotional status • Expectations
Social	• Culture • Values • Economic status • Environment • Social support • Coping mechanisms • Spirituality • Ethnicity • Education

TABLE 7.5 Factors Affecting the Perception of Pain

REAL RN STORIES

Nurse: Kevin, BSN
Years in Practice: Twelve
Clinical Setting: Medical-surgical unit in a rural hospital

Geographic Location: Rural Alabama

The community in which our hospital is located experiences a high rate of homelessness, higher than the average rate in the United States. During the cold winter months, we typically see an increase in persons without housing seeking care in the emergency department (ED).

It was a cold winter night in December when I received a phone call from a nurse in the ED that I was getting a new patient. The patient was a 46-year-old female who was without housing and complaining of back pain. The ED nurse mentioned the patient was a "frequent flier" and a "pain seeker." The nurse didn't know why the patient was being admitted other than "to have a warm place to sleep for the night." The nurse reported that the patient had been given a heat pack but no pain medications. The nurse went on to mention the patient was seen in the ED one week prior, testing was done at that time, and no source of pain was found.

Upon arrival to the unit, the patient was displaying physical signs of pain, such as rocking back and forth, and stated she was in pain. A comprehensive pain assessment was performed, with the patient rating the pain as a 10/10 using the numerical rating scale. I felt uncertain how to proceed in that moment. My assessment told me the patient was in pain, but given the report from the ED nurse and noting the patient's frequency of ED visits, I began to wonder if the patient really was in pain or if they were just seeking pain medications and a warm place to sleep.

I continued to ask the patient questions to gain a better understanding of the pain. During the assessment, the patient asked to use the restroom. It was at that time that I noted blood in the urine. I asked several follow-up questions and discovered the patient had been feeling a burning sensation with urination. Realizing the cues were signs of a possible kidney stone or kidney infection, I provided the patient with pain medications and notified the provider. The patient ended up having a kidney stone, which was treated. Once the problem was resolved, the patient did not complain of further pain.

Looking back on the situation, I should have recalled that as a nurse, I must be nonjudgmental and recognize that pain is subjective and whatever the patient says it is. The patient was demonstrating physical signs of pain and was sufficiently cognitively aware to provide a pain score. I am glad I decided to ask additional questions to probe the patient a bit further. Had I not done this, I wonder if the patient's underlying condition would have been identified and treated. All patients have a right to adequate pain control, which starts with believing what the patient says they are experiencing.

Pain Scales

A key factor when assessing pain is to determine the severity of the pain. Because nurses cannot test pain objectively to determine what someone is experiencing, providers use pain scales to gain a concrete understanding of a patient's pain. These tools may also be used to establish a reasonable pain goal the patient would like to reach. Although nearly all patients would like to have a pain goal of 0, this may not be reasonable for a given individual. For example, someone who just had surgery should expect to have pain for at least several days, and possibly longer.

Nurses have the option of using several standardized pain scales. The most common is the **numerical rating scale (NRS)**. When using this scale, patients are asked to rate their pain between 0 and 10, with 0 being no pain and 10 being the worst pain ever experienced. Typically, a pain score of 0 means no pain, a score of 1 to 3 is mild pain, a score of 4 to 6 is moderate pain, a score of 7 to 9 is severe pain, and a score of 10 is unbearable pain. Severity ratings may vary according to institutional policy. Although simple and easy to use, this pain scale cannot be used for children or others who cannot quantify the severity of pain. As such, these populations require alternative pain scales, such as the FACES scale, FLACC scale, PAINAD scale, behavioral pain scale (BPS), or critical-care pain observation tool (CPOT).

LINK TO LEARNING

The University of Florida Health has created a web page that links to many different pain assessment tools (https://openstax.org/r/77PainAssmtTool) as part of their Pain Assessment and Management Initiative.

The **FACES scale** is a visual tool for assessing pain in children ages 3 and older and others who cannot use a

numerical scale. To use the FACES scale, first explain to the patient that each face represents a person who has no pain (or "hurt"), some pain, or a lot of pain: for example, "Face 0 doesn't hurt at all. Face 2 hurts just a little. Face 4 hurts a little more. Face 6 hurts even more. Face 8 hurts a whole lot. Face 10 hurts as much as you can imagine, although you do not have to be crying to have this worst pain." Ask the person to choose the face that best represents the pain they are feeling. Although simple to perform, the results are not always reliable, and additional assessments may help to determine the severity of the patient's pain.

The **FLACC scale** is used to assess pain in children between the ages of 2 months and 7 years, as well as those unable to verbally communicate. This scale has five criteria: face, legs, activity, cry, and consolability. Based on their observations of the patient, the provider assigns each of the five criteria a score of 0, 1, or 2. The provider then adds the scores of each of the five criteria to calculate the overall pain score. The overall total will be between 0 and 10, with 0 being no pain and 10 being severe pain.

The **pain assessment in advanced dementia (PAINAD) scale** is used to assess pain in patients with Alzheimer disease and advanced dementia. This scale has five criteria: breathing independent of vocalization, negative vocalization, facial expression, body language, and consolability. Similar to the FLACC scale, each of the five criteria in the PAINAD scale are assigned a score of 0, 1, or 2. The provider observes the patient, assigns a score for each criterion, and adds the scores. The total pain score will be between 0 and 10, with 0 being no pain and 10 being severe pain. Like FLACC, the PAINAD scale is simple, valid, and reliable, but it may not always result in the most accurate pain assessment, because it requires the nurse to calculate the score based upon observed patient behaviors rather than the patient's subjective pain rating.

The **behavioral pain scale (BPS)** is a tool used to assess and quantify pain in acute sedated ventilated patients in intensive care units (ICUs). This scale relies on the observation of facial expressions, upper limb body movements, and compliance with mechanical ventilation. BPS scores range from 3 (no pain) to 12 (maximum pain).

The **critical-care pain observation tool (CPOT)** is another standardized assessment tool used in critical-care settings to evaluate pain in critically ill patients who are unable to communicate their pain. The CPOT measures pain through the observation of four behavioral categories: facial expressions, body movements, muscle tension, and compliance with the ventilator (for intubated patients) or verbalization (for extubated patients). CPOT scores range from 0 (no pain) to 8 (maximum pain).

Pain Assessment for Older Adults

In general, persistent pain has been related to depression, anxiety, decreased socialization, sleep disturbances, and slowed mobility. It is therefore crucial that nurses adequately assess and treat pain to maintain the health, well-being, and functional status of older patients, who are more likely to experience pain yet less likely to report being in pain. This is partly because both providers and patients may be inclined to dismiss pain as a normal part of aging. There are also valid concerns about the risks of pain medications leading to opioid dependence, as well as a lack of routine pain assessments that are comprehensive in nature. All these factors have resulted in undertreatment of pain in the older adult population.

A multimodal approach to assessing pain, both by observing physical cues and utilizing tools such as the FACES or PAINAD scales, is essential for treating older adults. If the patient is cognitively impaired or unable to communicate, the nurse should rely heavily on any physical cues noted and treat the patient accordingly.

CLINICAL SAFETY AND PROCEDURES (QSEN)

Pain Assessment Checklist

Disclaimer: Always follow the institution's policy for pain assessment.

Special considerations:

- Provide developmentally and culturally appropriate education based on the needs of the individual.
- Explain to the patient and family that pain control is the patient's right.
- Encourage questions, and answer them as they arise.

Steps	Additional Information
1. Ensure hygiene.	• Performing hand hygiene and donning appropriate personal protective equipment reduces the spread of microorganisms.
2. Introduce yourself.	• Patients have a right to know who is providing care to them.
3. Verify patient identity.	• Verify patient identity using two identifiers, such as name and date of birth.
4. Assess risks for pain.	• Consider factors, such as if the patient has recently undergone surgery or an invasive procedure, conditions that are likely to cause pain (e.g., cancer, sickle cell anemia), anxiety, inability to communicate, cognitive impairments, or advanced age.
5. Assess pain using a pain scale.	• Use scale appropriate for the patient's age and cognitive level. • Consider age- and cultural-related factors that may prohibit patient from reporting pain.
6. Establish a pain goal with the patient.	• Using the same pain scale, ask the patient to set a reasonable pain goal.
7. Determine the classification of pain.	• Identify if the pain is nociceptive or neuropathic.
8. Determine whether pain is acute or chronic.	• Determine how long the pain has been present. Typically, chronic pain is pain that has lasted longer than six months.
9. Assess response to previous pharmacologic interventions, including analgesics.	• How have other medications affected sleeping, eating, vital signs? • Has the patient experienced unwanted symptoms with medications in the past, such as itching, nausea, or vomiting?
10. Assess the pain site.	• Inspect: Do you notice any swelling, draining, bruising, lumps, or other discolorations? • Palpate: Are there painful areas, changes in body temperature, or evidence of altered sensation? • Assess range of motion to determine effect on joints. • Perform percussion and auscultation to determine potential cause of pain.
11. Assess for physical, behavioral, and emotional signs of pain.	• Look for signs, such as moaning, crying, grimacing, clenched teeth, irritability, confusion, diaphoresis, guarding, muscle tension, restlessness, fatigue, insomnia, depression, abnormal gait, decreased activity, or social withdrawal.
12. Assess characteristics of pain.	• Use COLDSPA, OLDCARTES, or PQRSTU mnemonics.
13. Assess patient's preferences in pain management.	• Consider cultural factors that may affect pain management. • Identify preferences in nonpharmacological supportive therapies.

Reassessment after Intervention

Pain should always be reassessed after implementing an intervention to determine the effectiveness of the intervention in reducing the pain. Typically, pain should be reassessed within one hour of administering oral medications and within fifteen to thirty minutes of administering intravenous medications, depending upon institutional policy. Reassess pain utilizing the same pain scale as the initial pain assessment. If the patient's pain has not decreased to a level equivalent to their established pain goal, discuss further interventions. These interventions may include additional medications or nonpharmacological modalities, such as heat, ice, music, and repositioning. Intervention (both pharmacological and/or nonpharmacological) and reassessment are required until achieving the patient's optimal pain goal. Chart all reassessments and interventions in the medical record.

READ THE ELECTRONIC HEALTH RECORD

Documenting Pain Assessments

The following is a sample of nursing documentation within an electronical health record (EHR) for pain management. The patient is a 42-year-old male who experienced a stroke. He is NPO because he has swallowing difficulties and has impaired balance, so he cannot ambulate without the assistance of two people. He has expressive aphasia, so the words he says are not the words he means. His last bowel movement was three days ago.

7.3 Pharmacological Pain Management

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Differentiate among types of pharmacological methods of pain management
- Describe the nurse's role in educating patients about pharmacological pain management therapies

Pain management can involve pharmacological and nonpharmacological therapies. Therapy that involves drugs or medications is called **pharmacological therapy**. This section explores pharmacological methods for pain management and the nurse's role in educating patients on pharmacological pain management therapies.

Types of Pharmacological Pain Management

A pain medication may be classified as an **analgesic**, a medication used to prevent or treat pain, or an **adjuvant**, a medication that has an independent analgesic effect but also an additive analgesic property when administered with an opioid; an adjuvant is also called a **coanalgesic**. Examples of adjuvants are antidepressants and anticonvulsants. They are used for depression and seizure control, respectively, but are also administered to enhance the effects of pain medications. Analgesics may be further classified as opioids or nonopioids. An **opioid** is a class of drugs derived from opium, a chemical sourced from poppy plants. A **nonopioid** is a medication that is not an opioid.

When administering analgesics, start with the medication that has the fewest side effects, in the smallest dose possible, via the least invasive route. The World Health Organization (WHO) developed a pain ladder (Figure 7.3) that was originally used to guide pain control for cancer patients; it applies to all types of pain, however, and has since been expanded to distinguish between increasing and decreasing pain intensity. Nonopioids should typically be the first choice to control pain, because they typically have fewer side effects than opioids and are less likely to result in addiction. If pain persists or increases, then opioids may be added as additional therapies in combination with nonopioids and adjuvant therapies. For pain that is severe and expected to decrease over time, opioids, nonopioids, and adjuvants may be given first, with adjuvants and opioids being removed from the regimen over time so the patient is eventually taking just the nonopioid medications.

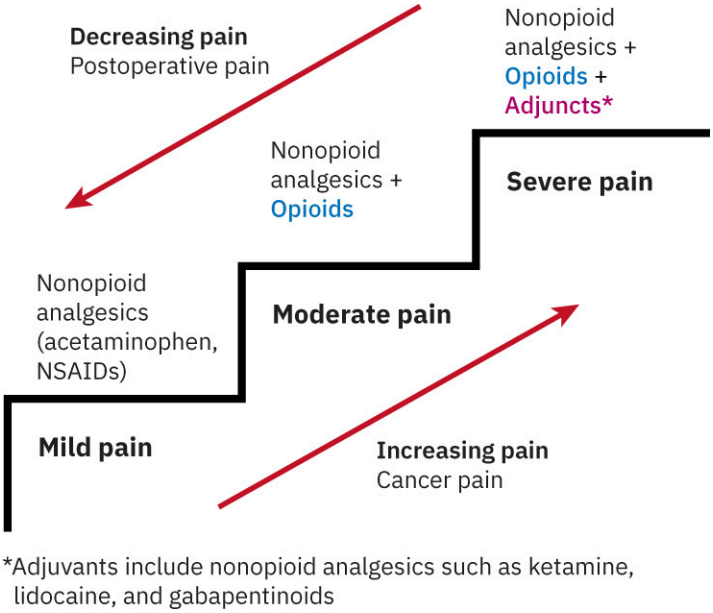

FIGURE 7.3 The WHO pain ladder is a guide for using pain medications responsibly. (credit: modification of "The World Health Organization (WHO) pain ladder modified for Acute Pain Management." by Gai, Nan & Naser, Basem & Hanley, Jacqueline & Peliowski, Arie & Hayes, Jason & Aoyama, Kazuyoshi/*Journal of Anesthesia*, CC BY 4.0)

INTERDISCIPLINARY PLAN OF CARE

Pain Management from a Physical Therapy Perspective

Physical therapy (PT) is a key intervention for physical rehabilitation, but patients often report an increase in pain severity during their therapy sessions. To maximize the patient's participation in physical therapy exercises, pharmacological pain management therapies may be administered thirty to sixty minutes before the therapy session. Physical therapists will often notify the patient's nurse of an upcoming session and request the pain be premedicated prior to treatment. The therapy session will then begin thirty to sixty minutes later once the pain medication has taken effect.

Analgesic medications, including opioids and nonopioids, can prevent or treat pain. Nonopioids typically treat mild to moderate pain, and patients tolerate them well. Opioids are used to treat moderate to severe pain.

Analgesic Medications: Nonopioids

Nonopioid analgesics include acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs). Acetaminophen is used to treat mild pain and is typically safe for all age groups. Because it may be administered via several routes, including orally, rectally, and intravenously, it may be a good choice for those unable to take oral medications. Use it sparingly in patients with liver failure, because hepatotoxicity (severe liver damage) is a potential side effect. Thus, it is important to carefully monitor the daily intake of acetaminophen. Older adults should take no more than 3,200 mg in a twenty-four-hour time frame, whereas healthy younger adults should take no more than 4,000 mg; patients with alcohol use disorder should take no more than 2,000 mg. It is important to include all sources of acetaminophen in the daily totals, including amounts of the medication found in combination medications. For example, Percocet 5/325 contains 5 mg of oxycodone and 325 mg of acetaminophen. If the patient were to take one tablet of Percocet, the 325 mg of acetaminophen would count toward their daily intake of acetaminophen. It is also important to ensure that combination medications are not administered too close to another time for administering acetaminophen. For example, if 500 mg of acetaminophen is ordered every four to six hours for fever and Percocet 5/325 is ordered every four to six hours for pain, the nurse must recognize that both medications contain acetaminophen and carefully consider how much acetaminophen is administered within the four-to-six-hour time frame, as well as be aware of the total dosage amount of acetaminophen administered within the twenty-four-hour period.

Nonsteroidal anti-inflammatories treat mild to moderate pain or inflammation; they may also be used in combination with opioids to treat severe pain. Examples of NSAIDs include ibuprofen, naproxen, and ketorolac. Ibuprofen is typically prescribed every six to eight hours and is safe for individuals 6 months of age and older. Naproxen is typically prescribed two to three times per day and is longer-acting than ibuprofen. Ketorolac is used for short-term treatment (up to five days) of moderate to severe pain in adults. It is the last line of nonopioids before opioids are prescribed and can be used to treat breakthrough pain for patients already taking opioids. Use a reduced dose of ketorolac for patients aged 65 and older because of the risks of stomach or intestinal problems; swelling of the face, feet, or lower legs; and sudden decrease in urine production. Side effects of NSAIDs can include dyspepsia, nausea, and vomiting. To reduce the risk of these side effects occurring, administer NSAIDs with food. Most NSAIDs also increase the risk of heart attack, stroke, and heart failure, particularly if taken in large doses or over prolonged periods of time, except for aspirin, which in low doses can decrease the risk of a second heart attack in people who have already had one. For some people, NSAIDs may also cause gastrointestinal bleeding, particularly if administered in combination with warfarin or corticosteroids, and renal failure.

LIFE-STAGE CONTEXT

Use of NSAIDs and Acetaminophen in Older Adults

Use NSAIDs and acetaminophen cautiously in older adults. These patients may have difficulty with the first-pass effect in the liver and are slower metabolizers than younger patients, putting them at risk for greater side effects and adverse effects. Adverse reactions associated with these analgesic medications include gastrointestinal,

cardiovascular, renal, and hematologic side effects. Prescribing these medications to older adults requires consideration of individual patient risk factors, benefits and risks of the medication, and patient education. In addition, these patients should be carefully monitored for effectiveness and side effects.

Analgesic Medications: Opioids

Opioids treat moderate to severe pain by blocking the release of neurotransmitters involved in sending pain signals. Opioids may be administered via a variety of routes, including oral, intramuscular, intravenous, subcutaneous, rectal, and transdermal. Typically, oral opioids, such as codeine, hydrocodone, and oxycodone, are used to treat moderate pain. Stronger opioids, such as fentanyl, hydromorphone, and morphine, may be used to treat more severe pain. Morphine is commonly used for cancer and end-of-life pain because it is not associated with a **ceiling effect**, the point at which the effect of a drug plateaus, so that increasing the dose will not increase the effect. Because morphine does not have a ceiling effect, increasing the dose will result in an increased effect of the medication.

Although opioids are very effective at managing pain, they can be highly addictive and must be used with caution. Of the potential adverse effects of opioids, the most serious is respiratory depression. Monitor patients receiving opioids for decreased respiratory rate, oxygen saturation, and heart rate. Patients at greatest risk for respiratory depression are those taking opioids for the first time, people receiving an increased dose of opioids, or individuals taking benzodiazepines or other sedatives, including alcohol, concurrently with opioids. Opioid-induced respiratory depression is treated with naloxone Figure 7.4, which immediately reverses all analgesic effects.

FIGURE 7.4 Naloxone comes in a variety of preparations, including nasal spray (pictured here), auto-injector, and injectable. (credit: "Flieger des 178. Flügels erhielten Nalaxone (Narcan)" by "Zusammenfassung"/U.S. National Archives & DVIDS, Public Domain)

The American Medical Association has created a video that demonstrates how to administer naloxone (https://openstax.org/r/77UseOfNaloxone) to a patient.

Monitor patients taking opioids for less severe side effects as well, such as constipation, nausea and vomiting, urinary retention, and itching. Opioids slow peristalsis and increase reabsorption of fluid into the large intestines, thereby slowing the passing of stool and removing the fluid from the stool so that it becomes concrete-like. It is important for the nurse to assess bowel functioning and encourage fluid and fiber intake and ambulation throughout the course of opioid treatments. The provider will also typically prescribe a bowel management program that includes a stool softener (such as docusate) and a stimulant laxative (such as sennoside, bisacodyl, or milk of

magnesia). If patients experience nausea and vomiting, antiemetics (such as prochlorperazine or ondansetron) may be prescribed. If patients experience urinary retention, they may require urinary catheterization, but this should not be used long-term. Antihistamines (such as diphenhydramine) may treat itching, but they may cause drowsiness and exacerbate the potential for opioid-induced respiratory depression.

The concept of **patient-controlled analgesia (PCA)** entails the patient self-administering opioid medications—including morphine, hydromorphone, and fentanyl—using a programmed pump. The medication syringe is locked inside a computerized pump that is attached to the patient's intravenous (IV) line. The lock ensures the medication cannot be accessed or tampered with. The programming of the pump is also locked to ensure the medication is infused at the intended rate and volume.

The patient self-administers doses of the medication on an as-needed basis by pressing a button. The patient may deliver a dose of medication according to a preset number of minutes or doses per hour (lockout interval). If these criteria are met, the PCA button lights up, signaling to the patient that they can administer a dose when needed. If the button is not lit up, the patient can still press it, but a dose of the medication will not be delivered. Some pumps deliver a continuous amount of medication, with the patient able to self-deliver additional doses as needed. Additionally, the provider may order a loading dose, or bolus, administered during initiation of the PCA.

PCAs may only be used for patients who are alert, oriented, and can independently press the button. Because small doses of opioids are administered frequently, it is important to monitor patients for oversedation and respiratory depression. Education for patients and their visitors is an important part of using a PCA. To reduce the risk of these adverse events, the patient and all caregivers should understand that no one should press the PCA button except for the patient. Nurses should also ensure that the PCA button and call light are easily within the patient's reach, along with any other interventions designated by the institution for patients who have a high fall risk (such as bed in low position, bed alarm on, high-fall-risk armband, red socks), because patients on PCAs are at a high risk for falling.

Considering the potential for harm if a medication error were to occur with a PCA, both the incoming and outgoing nurses during shift change should confirm pump settings. Each nurse should independently double-check to ensure the correct drug, concentration, doses (loading dose, PCA demand dose, continuous dose), and lockout interval. Two nurses are also needed when providing a bolus, changing any of the settings, and replacing the medication syringe to double-check for errors.

When a patient is on a PCA, it is important to monitor their vital signs to identify potential signs of respiratory depression, such as decreased respiratory rate, oxygen saturation, and heart rate. The nurse should follow their organization's protocols for administering PCA medications, including frequency of vital signs. Typically, baseline vital signs should be taken prior to beginning the PCA, for a certain period of time after beginning the administration, and then every two hours for the duration of the PCA. The nurse should also perform a pain and sedation assessment using scales, such as the Richmond agitation sedation scale (RASS) or the Pasero opioid-induced sedation scale. Additionally, the volume infused should be captured as intake fluid, according to the protocols.

LINK TO LEARNING

Visit this site to see a PCA documentation checklist (https://openstax.org/r/77PCSdocChkLst) from Kaweah Health. Nurses are responsible for documenting PCA use.

Prior to initiating a PCA, document the patient's vital signs, PCA settings, and dual verification of the initial setup. Typically, the patient's pain level, alertness, respiratory rate, and oxygen saturation will be monitored every fifteen minutes after the initial setup, then every hour for four hours, followed by every two hours for the duration of the PCA; however, always follow the frequency of monitoring established in the institutional policy. The nurse must also document the volume of medication administered, which may be documented every four hours, at the end of every shift, or according to the institutional policy. The medication administered via the PCA is generally an opioid or narcotic, so it is the responsibility of the nurse to account for the amount used and correctly dispose if necessary.

Watch this video for a step-by-step demonstration of how to set up a PCA (https://openstax.org/r/77PCSsetup) on the Alaris PCA pump module.

Coanalgesic Medications

Coanalgesics are medications that have analgesic effects but their primary indication is not pain relief. For example, antidepressants are used to treat depression but they may also be used to treat chronic pain and pain-related symptoms, such as sleep problems and muscle spasms. Anxiolytics are primarily used to treat anxiety, but they may also treat chronic pain and pain-related anxiety and help to relax muscles. Anticonvulsants are used to treat seizures because they block pain receptors, but they may also be used to treat certain types of neuropathic pain. Corticosteroids are used to reduce inflammation, but they also reduce neuropathic pain by lessening signals from injured nerves.

Nursing Responsibility for Patient Education

It is the nurse's responsibility to properly educate patients on pharmacological pain interventions. Education should be culturally sensitive and linguistically appropriate for the patient. When providing culturally sensitive and linguistically appropriate education, nurses help the patient to understand the treatment plan, improve adherence to the plan, alleviate fears, set realistic expectations, discuss concerns, and build a relationship based on mutual respect—all of which will improve health, well-being, and patient outcomes.

Education should begin at treatment initiation and continue throughout the course of therapy. To be most effective, the approach should be tailored to the individual patient's needs. Consider the primary language spoken by the patient, as well as the patient's culture, age, cognitive function, and health literacy level. It is important to use simple language, define technical terms, ask open-ended questions, and provide visual materials, such as demonstrations, videos, pictures, or handouts.

Patients should be informed that pain management is a patient right. It is important to stay ahead of the pain by not waiting until the pain is severe before taking medications. Once the pain becomes severe, it will be much more difficult to control the pain and may require stronger pain medications to manage the pain. The nurse should also help patients understand the typical progression of pain medications according to the pain ladder. It is important for the patient to understand the need for starting with nonopioids before adding opioids and finally adjuvants to the pain medication regime. Patients with acute pain that is severe in nature, such as surgical pain, should know that opioids may be used to treat the initial pain but that the goal is to transition from intravenous opioids to oral opioids and eventually to nonopioids.

Patients should also be instructed of the need to use the smallest dose possible to achieve the intended pain goal. For example, if the provider has ordered one to two tablets every four to six hours upon discharge, then best practice is to advise the patient to start with one tablet, reassess their pain, and then take the other tablet if needed. It is much easier to add more pain medication, as needed. Patients should be told not to take more than the prescribed dose, as well as the risks of doing so.

LINK TO LEARNING

Read this position statement on the ethical responsibility to manage pain and the suffering it causes (https://openstax.org/r/77PainEthics) from the American Nurses Association.

The first time a medication is administered, the patient should be educated on the medication name, dose, route, and frequency at which they should take the medication. It is important to note if the medication should be taken at a certain time of day, if they should take the medication with food, and any other instructions for administering the medication. It is also important to review how to store the medication, including how to keep medications safely away from children by keeping them out of reach or locked up.

Any time a medication is given, patients should be educated on the potential medication side effects, as well as when to report side effects. With opioids, instruct patients on the risks for constipation, respiratory depression, and addiction. It is important for the patient to understand that the medication may make them drowsy. They should be told not to drink alcohol, drive or operate heavy machinery, or take medications that the prescriber is not aware of while taking opioid medications.

Patients will sometimes have misconceptions about pain management that need to be addressed. It is important to assess the patient's understanding of pain management and to address any misconceptions. For instance, a patient may not want to take opioids for fear of becoming dependent on them. Although it is true that opioids may lead to dependency with long-term use, it is important for the patient to understand the benefits of short-term use and the plan that will be followed to ensure they are tapered off opioids as quickly as possible.

7.4 Nonpharmacological Pain Management

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe different types of nonpharmacological pain treatment and their effectiveness
- Analyze the nurse's role in pain management using nonpharmacological methods
- Describe the nurse's role in educating patients about nonpharmacological pain management therapies

Nonpharmacological interventions can be used with or without pharmacologic interventions. They often provide tremendous benefits to the patient, who can choose from a variety of techniques based on what best fits their needs and goals. Like all treatments, nonpharmacological interventions should be documented in the plan of care and their effectiveness evaluated in terms of their ability to meet the patient's goals for pain relief.

Nonpharmacological Pain Management

Nonpharmacological pain management techniques may be categorized as complementary or alternative medicine. Although these terms are sometimes used interchangeably, there is a distinct difference. A therapy that is used in combination with pharmacological pain management is called a **complementary therapy**, whereas one used in place of pharmacological pain management is called an **alternative therapy**.

Physical Modifications

Physical interventions include techniques such as rest, compression, elevation, and thermotherapy. Slight adjustments to the patient's environment may also alter the patient's response to pain. For example, adjusting the temperature in the room—making it warmer or cooler—may cause the patient to feel more comfortable. Other strategies include dimming the lights, reducing loud noises, and closing the patient's door.

To provide the opportunity for rest, consider clustering care (planning to include care tasks in as few visits as possible) to reduce unnecessary interruptions. Rest is important whether the pain is caused by illness or injury, as it allows the body to focus on healing. As much as possible, patients should avoid moving the injured body part, keeping weight off it, and using assistive devices, such as canes, crutches, splints, braces, or wheelchairs. Nurses can also support an injury by tightly wrapping the area in a compression bandage such as an ACE wrap. When using a compression bandage, the nurse must carefully assess the area to ensure proper blood flow to the extremity.

A treatment called **thermotherapy** is the application of heat or cold to alter the cutaneous, intra-articular, and core temperatures of soft tissues. Hot and cold therapies are one of the most commonly used nonpharmacological strategies for managing pain. Heat decreases pain by increasing blood flow through vasodilation, which promotes relaxation and alleviates muscle stiffness or chronic pain. Heat may be applied for five to twenty minutes at a time. Heat can be beneficial for chronic or ongoing issues, such as chronic back pain, muscle stiffness, and menstrual cramps. Cold decreases pain by reducing the blood flow through vasoconstriction; it also numbs nerve sensations. Cold should be applied for no longer than twenty minutes at a time. Cold is frequently given first after an injury to decrease inflammation, which will help decrease pain. It can be beneficial for various types of acute injuries, such as sprains and strains. Later heat may be applied to increase circulation, which then helps deliver oxygen and nutrients for healing. Heat and ice should never be directly applied to the skin. The nurse should routinely examine the site to assess for potential skin burns.

A combination of these strategies may be used to control pain for mild to moderate injuries, such as sprains, strains,

and bruises. A combination referred to as RICE, stands for rest, ice, compression, and elevation. RICE is most effective when implemented immediately following an injury, and for the twenty-four to forty-eight hours that follow, to decreased inflammation, pain, and risk for further injury. After the first forty-eight hours, the goals of care often shift from reducing inflammation and further injury, to supporting tissue healing and rehabilitation, while managing any residual pain or discomfort. Therefore, the use of RICE may be modified or reduced after the first forty-eight hours to support the patient's healing and mobility progress.

Mind-Body Therapies

Mind-body therapies take advantage of the fact that although pain begins in the body, it is perceived in the mind. One simple way to keep the patient's mind off their pain is to distract them, for example, by watching TV, playing games, reading, coloring, dancing, or telling jokes. Research has also shown that virtual reality may ease pain, particularly in pediatric patients (Tas et al., 2022; Teh et al., 2024). This technique allows patients to fully immerse themselves in a computer-generated, 3-D, virtual environment and engage in games and other methods of entertainment. Another approach to mind-body therapy is through **cognitive behavioral therapy (CBT)** in which individuals are taught how to manage and cope with pain more effectively by changing their negative thought pattern, identifying and reducing stressors that exacerbate pain perception, and focusing on adapting to pain in situations when pain cannot be eliminated.

Relaxation therapies may also be used for pain management. Activities that promote relaxation can be as simple as listening to music, praying, or breathing rhythmically, but more involved techniques are also available. For example, patients may be guided to create positive **guided imagery**, pleasant images in the mind, such as relaxing on a beach or strolling through a forest; to engage in **meditation**, the practice of breathing and repeating certain sounds or words, such as "om" or "gratitude," to put the mind at ease; to practice **mindfulness**, focusing on the present moment to create awareness of thoughts, feelings, the body, and the environment; to participate in **hypnosis**, the creation of a trance-like state to enhance awareness of feelings, thoughts, and sensations; or to engage in **animal-assisted therapy**, using animals to reduce pain, anxiety, and depression.

Movement is also an important consideration for reducing pain stimuli. Stretching and strengthening routines, **therapeutic exercise**, can help to improve muscle strength and flexibility, reduce joint stiffness, and enhance range of motion. Patients can restore functional ability and quality of life through **physical therapy**, manipulating joints and soft tissues in a manner that is tailored to the individual's specific needs. Certain movements can also help to decrease pain and promote relaxation. For example, **tai chi** is a practice that combines exercise and meditation through slow body movement and controlled breathing, and **yoga** is the practice of using specific stretches, poses, meditation, and controlled breathing to balance the mind and body (Figure 7.5).

FIGURE 7.5 Tai chi and yoga are practiced by many different people for a variety of reasons, including to help manage pain. (credit: "Hatha yoga in Japanese @ Semperviva" by "GoToVan"/Flickr, CC BY 2.0)

Natural Therapies

Natural products are those found in nature rather than synthesized by humans in a lab. They include herbs, vitamins, and other dietary supplements. All these remedies may add small amounts of necessary nutrients to the body, though they are not regulated by the Food and Drug Administration (FDA) for safety and effectiveness.

The inhalation or dermal application of essential oils—**aromatherapy**—is another strategy that can be used for nonpharmacological pain management. Essential oils are extracted from flowers, fruits, leaves, or seeds; they capture the smell of the plants from which they are derived. Studies have shown aromatherapy can be used not only to manage pain but also to reduce anxiety, calm stress, boost immunity, and improve sleep quality (Tanvisut et al., 2018; Gong et al., 2020). Essential oils linked to pain relief include lavender, rose, peppermint, eucalyptus, and chamomile.

LINK TO LEARNING

The National Institutes of Health has created fact sheets about herbal remedies (https://openstax.org/r/77HerbalRemedy) that identify their potential uses, side effects, cautions for use, and interactions with other drugs.

Certain diets, such as vegan or Mediterranean, have been shown to decrease inflammation in the body (Schieber & Mank, 2023). Research shows that anti-inflammatory diets can be particularly helpful for those with fibromyalgia and chronic pain. Anti-inflammatory diets typically recommend consuming numerous servings of vegetables, limiting dairy, refraining from simple carbohydrates with refined sugar, opting for whole grains, limiting red meat, and choosing lean proteins, such as fish, tofu, and legumes.

Manipulative Practices

Some pain can be relieved by physically working on or manipulating the body. For example, **massage** involves manipulating soft tissues to relieve tension, promote relaxation, and reduce pain. It may help to relieve lower back, neck, shoulder, cancer, arthritic, headache, and fibromyalgia pain. Due to the risk of injury if not performed correctly, massage should only be performed by trained individuals. It should be used with caution in patients on blood thinners or with wounds, fractures, blood clots, infection, or weakened bones.

Other types of manipulative practices include chiropractic therapy and reflexology. The practice that manipulates

the spine, joints, and skeletal system is **chiropractic therapy**. The type of massage applied to specific pressure points aligned with the body in the hands and feet is called **reflexology**.

Energy Healing

Energy healing is used to balance the flow of energy within the patient. Although considered an alternative therapy, there is anecdotal evidence to support its effectiveness, along with a growing scientific body of evidence exploring the clinical effectiveness of these therapies. One technique, **reiki**, entails one person placing their hands lightly on and above another person, with the intention of guiding energy throughout that person's body. Therapeutic touch also involves gently touching a person's body in order to affect its energy fields. Magnet therapy utilizes magnets on the body to reduce pain. Though there is limited evidence supporting the use of magnet therapy, it is thought to influence blood flow by attracting or repelling red blood cells, which could improve oxygenation and nutrient delivery and, in turn, promote healing and reduce pain. It is also thought that magnets could have an anti-inflammatory effect by affecting the ion channels in cell membranes and influence the perception of pain by altering the electrical activity in the nervous system.

A popular technique, **acupuncture** (Figure 7.6) is performed by inserting thin steel needles into the skin to stimulate specific points throughout the body. It is a traditional Chinese medicine that is used to rebalance the body's energy and prompt the body to release natural chemicals to relieve the body of pain. Acupuncture is commonly used to relieve chronic pain resulting from arthritis; back, neck, knee, and muscle pain; headaches and migraines; menstrual cramps; sports injuries; and nerve discomfort. It is not recommended for those with pacemakers, those taking blood thinners, or those who are pregnant.

FIGURE 7.6 Acupuncture is a traditional complementary therapy with Chinese origins that involves inserting small needles into the skin to stimulate specific parts of the body and its neural network. (credit: "A patient with acupuncture moxibustion in Nelson, New Zealand" by "Wonderlane"/Flickr, CC BY 2.0)

Electrical Stimulation

Another type of nonpharmacological pain management is **transcutaneous electrical nerve stimulation (TENS) therapy** (Figure 7.7), which delivers low-voltage electrical current to reduce pain. TENS therapies block or change the patient's perception of pain. Electrodes are placed on the body at or near where the relevant nerves are located. The electrodes are connected to a battery-powered device that delivers the electrical current. TENS therapy has been shown to relieve pain associated with osteoarthritis, fibromyalgia, labor pains, and diabetes-related neuropathy (Njogu et al., 2021; Wu et al., 2022). TENS therapy should not be used for those with an implantable device; those who have cancer, epilepsy, deep vein thrombosis, or hemorrhaging; or those who are pregnant.

FIGURE 7.7 TENS therapy is a method of pain relief involving the use of a mild electrical current. (credit: "January 18, 2014" by "osseous"/Flickr, CC BY 2.0)

Effectiveness of Nonpharmacological Pain Treatment

Although some nonpharmacological therapies have been scientifically proven to be effective in managing pain, it is important to note that some of these therapies are based on anecdotal evidence of effectiveness and lack scientific research to support their effectiveness (Vickers et al., 2017; Hilton et al., 2017; Thorn et al., 2011; Daily et al., 2016; Yuan et al., 2015). Plus, each patient's response to nonpharmacological therapies is unique. Nonpharmacological pain therapies may be extremely beneficial in reducing pain for some patients and ineffective in others. Effectiveness may also vary according to the type of therapy used. For example, one person may find massage useful at reducing back pain but acupuncture to be ineffective.

When formulating a pain management plan, it is important to meet the needs of the individual patient. For some, nonpharmacological therapies alone may manage the pain. Others may require pharmacological therapies or a combination of pharmacological and nonpharmacological. It is important to consider the risks and benefits of trying a nonpharmacological intervention to assess its effectiveness in managing pain versus not trying the therapy. Unless it will negatively affect the patient, it is generally acceptable to try different nonpharmacological therapies to see what works for the individual. Sometimes, this may even mean implementing several nonpharmacological interventions to serve as complementary therapies to each other.

CLINICAL JUDGMENT MEASUREMENT MODEL

Evaluating Outcomes: Exploring the Use of Nonpharmacological Approaches to Pain Management

The nurse notices an older adult patient grimacing and moaning. Upon recognizing the cues, the nurse completes a comprehensive pain assessment utilizing the PQRSTU mnemonic for pain assessment and determines the patient is experiencing pain (analyze cues). The nurse considers whether to administer pharmacological and/or nonpharmacological therapies (generate solutions). Understanding the risks associated with older adults taking analgesics, the nurse decides to start with nonpharmacological interventions first and repositions the patient (take action). Upon reassessment, the nurse notes the patient is resting comfortably, sleeping, and does not appear to be in pain (evaluating the outcome).

The Nurse's Role in Nonpharmacological Pain Treatment

The nurse's role in nonpharmacological pain treatment is to generate ideas about which therapies may be beneficial to the patient, implement the interventions, and then assess the effectiveness of the interventions. The nurse must first assess whether nonpharmacological treatments would be beneficial according to the patient's condition, as well as assess the patient's preferences for treatment. Just like treatments utilizing medications, nonpharmacological treatments should be reassessed within a reasonable time frame, and the patient's response to the intervention should be documented in the medical record. If the patient has not reached their identified pain goal, the nurse may then consider additional therapies to add to the treatment plan, followed by reassessment and documentation of the reassessment.

Collaboration between the provider and the patient is key. The nurse acts as a liaison between the provider and the patient to advocate for the most optimal therapeutic plan for pain control. There may also be times when the nurse must advocate for better pain control. For example, the nurse may need to discuss benefits of nonpharmacological interventions with some patients, whereas other patients may need to consider adding pharmacological interventions as complementary therapy. Although the ultimate treatment decision is up to the patient, collaborative discussions provide the patient with the necessary information to make an informed decision about their plan of care.

Patient Education

Complementary therapies deemed safe for healthy patients may not be safe for patients with certain medical conditions. It is important to instruct patients to discuss complementary therapies with their provider before initiating them. The provider will assist with decision-making to determine if the therapy is appropriate given the patient's condition and any other therapies they are currently receiving. Similarly, patients who opt for alternative therapies should be instructed to discuss the possible benefits and harms caused by initiating the alternative therapy versus using a pharmacological therapy. Patients should be informed to never stop taking their prescribed medications without first discussing their plan of care with their provider.

When completing medical histories, it is important to ask the patient about any dietary, herbal, or supplemental products they may be taking and to explain why it is important to add all such usages to their medication history. Patients should also be instructed to consult with their provider before beginning use of a supplemental product. Remind patients that a product labeled "natural" is not necessarily safe. For example, St. John's wart may interact with certain drugs, making them less effective. Taking vitamin K supplements with warfarin may reduce the effectiveness of the medication in thinning the blood.

7.5 Substance Use Disorder

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define substance use disorder (SUD)
- Identify measures for SUD prevention
- Discuss pain management strategies for patients with SUD

According to the Centers for Disease Control and Prevention (CDC) (2023), one in seven Americans reports experiencing a substance use disorder. It can happen to anyone and is not associated with a single driving factor. This section will define what a substance use disorder is, what preventative measures can be taken, and how to manage pain for those with these disorders. Emphasis throughout this section will be placed on opioids but similar measures apply with other substances as well.

What Is Substance Use Disorder?

A **substance use disorder (SUD)** is the disorder that occurs when the repeated use of alcohol and/or other drugs significantly impairs a person's health and results in an inability for them to meet major responsibilities at work, school, or home (Substance Abuse and Mental Health Services Administration, 2022). SUDs can occur with various drugs, including alcohol, cannabis, hallucinogens, inhalants, opioids, sedatives, hypnotics, anxiolytics, stimulants, and tobacco. SUD can be classified as mild, moderate, or severe.

The most severe form of SUD, **addiction**, happens when there is continued use of the substance despite negative consequences. It is important to note that addiction is a medical disease and not a description of someone's character. As such, persons with SUDs should not be referred to as abusers, addicts, alcoholics, or medication seekers, because these terms are negative and stigmatizing. Stigma associated with SUDs can be isolating and demoralizing, and it can hinder persons from seeking treatment. To reduce the stigma, instead focus on the medical diagnosis and specific SUD at hand.

Although SUD is defined as a chronic, treatable disease, recovering from an SUD can be difficult. Most persons with an SUD cannot simply stop taking the problematic drug, because changes to their usage can result in devastating withdrawal symptoms. In some cases, a different drug can be substituted to help wean the patient off the problematic one; these include methadone, buprenorphine, and naltrexone, all of which are used to treat patients addicted to stronger opioids. Patients may also participate in programs, such as twelve-step facilitation therapy, outpatient counseling to understand addiction and triggers, or inpatient rehabilitation at a full-time facility that provides a supportive environment for recovery without distractions or temptations. Providers use evidence-based guidelines to select a treatment plan that best meets the clinical needs of the patient.

Use of pain medications, particularly opioids, has the potential to become a SUD. One SUD, **opioid use disorder (OUD)**, is caused by a problematic pattern of opioid use. Because opioids activate the release of endorphins in the brain, resulting in feelings of pleasure, they are highly addictive. Unlike other causes of SUD, OUD is typically associated with a higher risk of physical **dependence**, which is when the person feels like they cannot function without the use of the substance. Dependence is not to be confused with **tolerance**, which is when the body requires more of a drug over time to achieve the same level of pain relief. If someone who is dependent on a drug reduces their dosage or stops taking it altogether, withdrawal symptoms will occur. Symptoms of **withdrawal** include sweating, confusion, enlarged pupils, loss of appetite, diarrhea, vomiting, cramps, tremors, yawning, and flu-like symptoms.

SUD has become a grave concern within the United States. According to the CDC (2023), approximately 1.6 million people in the United States suffer from OUD. Often, OUD results in opioid overdose. The frequency of drug overdose deaths increased by 30 percent from 2019 to 2020, with nearly 75 percent of drug overdose deaths involving an opioid (CDC, 2022a). It is estimated that 187 people die every day from opioid overdoses (CDC, 2022a). Considering the frequency of opioid deaths, the U.S. government declared the opioid crisis to be an epidemic and public health emergency in 2017 (Centers for Medicare & Medicaid Services, 2022). The severity of the opioid epidemic is illustrated by the data captured in Figure 7.8.

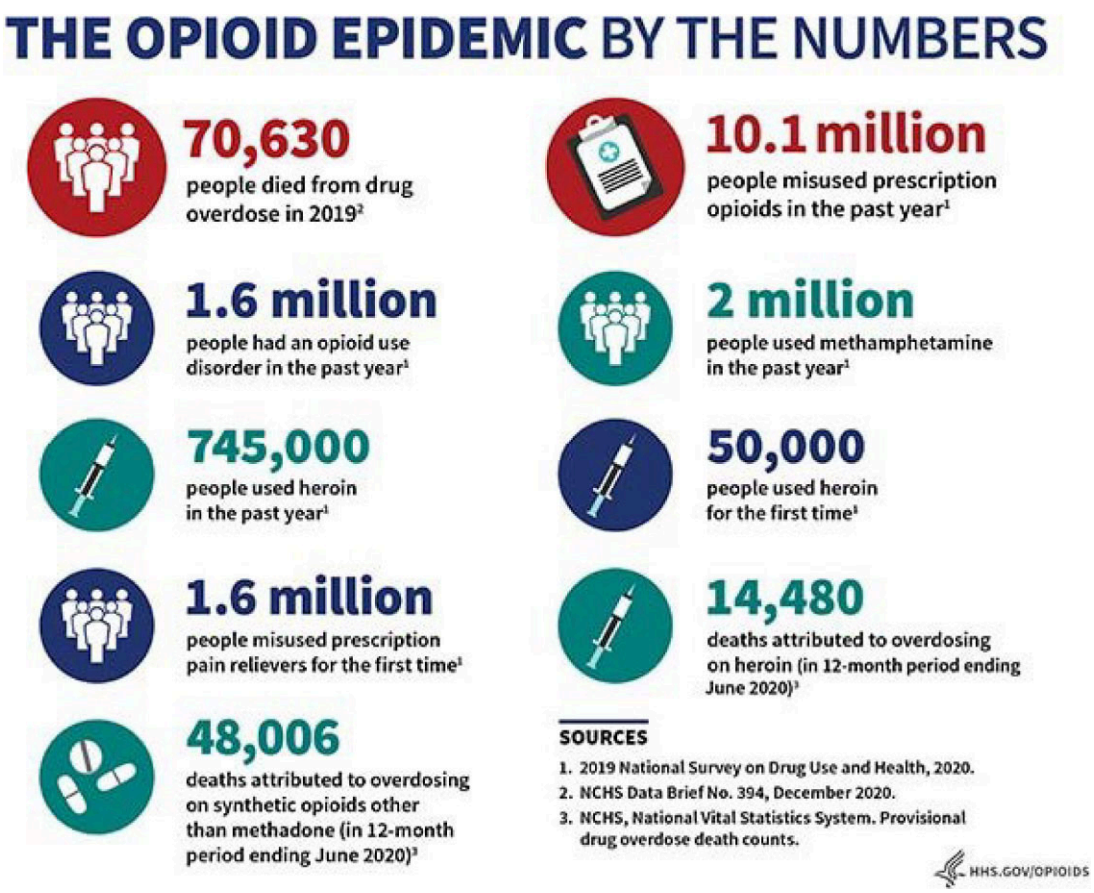

FIGURE 7.8 These data, from 2019 to 2020, show the number of people in the United States affected in different ways by the opioid epidemic. (credit: "Opioids by the Numbers" by U.S. Department of Health and Human Services/U.S. Department of Health and Human Services, Public Domain)

Preventing SUD and Addiction

Prevention is critical for reducing the prevalence of SUDs and addiction. The most effective way to prevent OUD is to reduce the frequency of prescribing opioids; if opioids are not prescribed, then they are much less likely to cause addiction. Education and awareness around the harms of substance use is also critical to gain the support of friends, families, and communities. People also need to be educated about ways to safely store and dispose of opioids.

The 2022 CDC Clinical Practice Guideline for Prescribing Opioids for Pain recommends providers review a patient's history of controlled substance prescriptions prior to prescribing opioids (CDC, 2022b). To do so, the provider can view the patient's history of prescribed opioid use via a prescription drug monitoring program (PDMP), an electronic database that tracks controlled substance prescriptions. PDMPs also inform providers of any other medications that a patient is taking that may place the patient at risk for overdose from an opioid. PDMPs can be very beneficial when the patient is transitioning to a new provider or the patient's medication history is unavailable. The PDMP should be checked prior to prescribing opioids and at least every three months when continuing opioid therapy.

LINK TO LEARNING

States have the primary responsibility to regulate and enforce prescription drug practices. The CDC's Public Health Law Program (https://openstax.org/r/77DrugMisuse) provides resources and legal developments regarding state laws on prescription drug misuse and abuse.

Managing Pain in Patients with SUD

Managing pain in patients with SUD can be tricky. All patients, regardless of whether they have an SUD, have the right to be treated with respect and to have their pain managed adequately. Each condition, both pain and SUD,

requires a multifactorial, patient-centered approach that may involve both pharmacological and nonpharmacological interventions. The SUD and the cause of the pain should be treated independently.

For patients with an OUD, maximize nonpharmacological therapies and nonopioid medications prior to treating the pain with opioids. Examples of nonpharmacological therapies that may be effective include therapeutic exercise, physical therapy, and CBT, as well as complementary and alternative medicines. Examples of nonopioid medications that may be used include NSAIDs, topical analgesics, and adjuvant medications, such as serotonin-norepinephrine reuptake inhibitors, tricyclic antidepressants, and antipsychotics.

If pain levels necessitate opioid use, then do not withhold opioids from a patient with an OUD. Just as for any patient, it is important to establish shared goals and known risks, form a treatment agreement, and ensure close monitoring with routine follow-up visits to reassess pain. Opioid doses should be titrated by starting with a low dose and increasing the dose slowly, as needed. Treatment agreements outline the course of action for the treatment, as mutually agreed upon by the patient and the provider. As always, the patient should be an active participant in the collaborative approach to determine a treatment plan that meets the needs of the individual. A sample treatment agreement is shown in Figure 7.9.

Rx Pain Medications

KNOW THE OPTIONS • GET THE FACTS

Prescription Drug Monitoring Programs (PDMPs)

PDMPs are a promising tool for curbing the misuse of prescription opioids.

Q: What Is a PDMP?

A: PDMPs are state-run electronic databases that collect patient-controlled substance prescription information submitted by dispensers. Although each state PDMP is governed by its own laws, many states are working toward interstate PDMP data sharing to allow users to access data across state lines.

Q: Why Are PDMPs Used?

A: PDMP information is a resource for health care providers and may help:

- Avoid duplicative therapy;
- Identify negative drug interactions;
- Prevent substance misuse or death; and
- Identify individuals who may need treatment.

Q: What About Patient Privacy?

A: When accessing a patient record through a PDMP, health care providers must abide by state and federal regulations for privacy. Although the details vary by state, health care providers are usually able to consult with other health care providers directly involved in a patient's care in order to ensure appropriate and adequate care. Check local laws for the most up-to-date information.

Use the following links for more details about your state's PDMP and safe, effective pain management:

Summary

7.1 Concepts and Causes of Pain

- Pain is an uncomfortable or unpleasant sensation that signifies injury or illness. Pain is caused by receptors in the body sending a signal to the brain to let an individual know that they are in pain.
- Pain is whatever the person says it is, when they say it occurs.
- Pain may be characterized as acute, chronic, or breakthrough according to its onset and duration. Acute pain lasts up to three to six months, chronic pain lasts longer than six months, and breakthrough pain is a sudden onset of pain lasting for a short period of time.
- Pain may also be characterized as neuropathic or nociceptive according to the type of damage that causes it. Neuropathic pain is caused by damage to nerves or other parts of the nervous system, whereas nociceptive pain is caused by damage to the body tissue.
- Pain may also be referred, which means that pain in one part of the body may be felt as pain in another part of the body.

7.2 Pain Assessment

- Pain is often considered the fifth vital sign, and pain assessments should be performed routinely to allow for better pain management by developing a treatment plan that meets the individual needs of the patient.
- Nurses should assess for the risks for pain, as well as its type, character, onset, location, duration, severity, pattern, and associated factors.
- The severity of pain may be assessed using a variety of tools, including the numerical rating scale, FACES scale, FLACC scale, PAINAD scale, behavioral pain scale, or CPOT. It is important to utilize the most appropriate pain scale according to the patient's age and condition.
- Nurses must remember that pain is subjective and whatever the patient says it is, whenever the patient says it is.
- Pain should be reassessed within one hour of intervention, or within fifteen to thirty minutes for intravenous interventions, according to institutional policy. Additional interventions (pharmacological and/or nonpharmacological) and pain reassessments are warranted until the severity of the pain reaches the pain goal identified by the patient.

7.3 Pharmacological Pain Management

- Pharmacological methods of pain management include opioids, nonopioids, and adjuvant medications.
- Nonopioids, such as acetaminophen and NSAIDs, are typically administered as a first-line defense for mild to moderate pain.
- Opioids may be administered for moderate to severe pain, but the patient should be carefully monitored for respiratory depression and addiction.
- Coanalgesics, or adjuvants, are not intended to treat pain but they produce an analgesic effect that can be used to help manage pain.
- It is the nurse's responsibility to provide education related to pharmacological pain management therapies in a manner that is culturally and linguistically appropriate for the patient. Patients should be educated on their right to adequate pain management, general medication information, potential side effects, expectations for pain management regimens, and safe medication storage. Nurses should also be prepared to dispute myths associated with pain medications.

7.4 Nonpharmacological Pain Management

- Nonpharmacological pain treatments are interventions that can be used to complement pain medications or as alternatives to medications. Examples of nonpharmacological interventions include cold and heat therapy, alterations of environmental stimuli, rest, TENS therapy, massage, and acupuncture.
- The nurse is responsible for assessing the need for nonpharmacological pain interventions, discussing the options with the patient, implementing the interventions, and evaluating the effectiveness of the interventions. Use of nonpharmacological methods should be a collaborative effort between the patient and the care team.
- The nurse should educate the patient on potential risks and benefits of treatments and inform the patient to

discuss use of any nonpharmacological interventions with their provider.

7.5 Substance Use Disorder

- A substance use disorder (SUD) is a disorder that occurs when the repeated use of alcohol and/or other drugs significantly impairs a person's health and results in an inability for them to meet major responsibilities at work, school, or home.
- SUDs are chronic diseases that may be treated with medications to avoid withdrawal; common treatments also include therapy and rehabilitation.
- The best way to prevent opioid use disorders (OUDs) is to reduce the frequency of opioid prescriptions.
- Other strategies to prevent OUDs include education regarding awareness of the harms of opioid misuse and methods for safely storing and disposing of opioids.
- Prescription drug monitoring programs also play an important role in preventing OUDs.
- Pain and SUDs should be treated independently using a patient-centered approach that may involve both pharmacological and nonpharmacological interventions. Sources of nonpharmacological therapies and nonopioid medications should be maximized prior to treating the pain with opioids; however, there may be times when opioids are required.

Key Terms

abnormal pain pain that moves beyond the expected severity and duration and may require additional medical treatment
acupuncture pain management technique that includes the insertion of thin steel needles into the skin to stimulate specific points throughout the body
acute pain short-term pain, typically lasting from minutes to up to three to six months
addiction most severe form of SUD, in which there is continued use of the substance despite negative consequences
adjuvant (also, **coanalgesic**) medication that has an independent effect and also additive analgesic properties when administered with opioids
alternative therapy treatment used in place of pharmacological pain management
analgesic medication used to prevent or treat pain
animal-assisted therapy treatment that utilizes animals to reduce pain, anxiety, or depression
aromatherapy inhalation or dermal application of essential oils
behavioral pain scale (BPS) tool used to assess and quantify pain in acute sedated ventilated patients in intensive care units (ICUs)
breakthrough pain sudden increase in pain that lasts for a short time
ceiling effect point at which the effect of a drug plateaus, so that increasing the dose will not increase the effect
chiropractic therapy pain management technique that manipulates the spine, joints, and skeletal system
chronic pain pain lasting longer than six months
coanalgesic (also, **adjuvant**) medication that has an independent effect and also additive analgesic properties when administered with opioids
cognitive behavioral therapy (CBT) psychological treatment in which patients are taught how to manage and cope with pain more effectively by changing their negative thought pattern, identifying and reducing stressors that exacerbate pain perception, and focusing on adapting to pain in situations when pain cannot be eliminated
complementary therapy treatment used in combination with pharmacological pain management
critical-care pain observation tool (CPOT) standardized assessment tool used in critical-care settings to evaluate pain in critically ill patients who are unable to communicate their pain
dependence inability to function without the use of a substance
FACES scale visual tool for assessing pain with children and others who cannot quantify the severity of their pain on a numerical scale
FLACC scale pain scale used to assess pain in children between the ages of 2 months and 7 years, as well as those unable to verbally communicate
guided imagery positive, relaxing images created in the mind
hypnosis creation of a trance-like state to enhance awareness of feelings, thoughts, and sensations
massage pain management technique that manipulates the soft tissues of the body to relieve tension and create

relaxation

meditation practice of breathing and repeating certain words to reduce stress and put the mind at ease

mindfulness practice of focusing on the present moment to create awareness of thoughts, feelings, the body, and the environment

neuropathic pain pain caused by damage to nerves or other parts of the nervous system

nociceptive pain pain caused by damage to body tissue

nociceptor type of sensory receptor that responds to potentially damaging stimuli by sending nerve signals to the spinal cord and brain

nonopioid medication that is not an opioid

normal pain pain of the expected severity and duration, according to its cause

numerical rating scale (NRS) pain scale that rates pain on a scale of 0 to 10

opioid class of drug derived from opium, a chemical sourced from poppy plants

opioid use disorder (OUD) type of SUD caused by a problematic pattern of opioid use leading to physical dependence

pain uncomfortable or unpleasant sensation that typically signifies injury or illness

pain assessment in advanced dementia (PAINAD) scale pain scale used to assess pain in patients with advanced dementia

patient-controlled analgesia (PCA) practice of allowing the patient to self-administer opioid medications using a programmed pump

phantom pain pain perceived to be coming from a missing body part

pharmacological therapy treatment that involves drugs or medications

physical therapy manipulation of joints and soft tissues to restore functional ability and quality of life

referred pain pain in one part of the body that is caused by pain in a different location of the body

reflexology pain management technique that applies massage to specific pressure points aligned with the body in the hands and feet

reiki pain management technique in which one person uses lightly placed hands to guide energy throughout another person's body

somatic pain pain experienced in the muscles, skin, or bone

substance use disorder (SUD) disorder that occurs when the repeated use of alcohol and/or other drugs significantly impairs a person's health and results in an inability for them to meet major responsibilities at work, school, or home

tai chi practice that combines exercise and meditation with slow body movement and controlled breathing

therapeutic exercise stretching and strengthening routines that can help to improve muscle strength and flexibility, reduce joint stiffness, and enhance range of motion

thermotherapy application of heat or cold to alter the cutaneous, intra-articular, and core temperatures of soft tissues

tolerance state of requiring more of a drug over time to achieve the same level of pain relief

transcutaneous electrical nerve stimulation (TENS) therapy treatment that delivers low-voltage electrical current to reduce pain

visceral pain pain experienced in the internal organs

withdrawal physical and mental symptoms experienced when a person suddenly stops or decreases the use of an addictive substance

yoga practice of using specific stretches, poses, meditation, and controlled breathing to balance the mind and body

Assessments

Review Questions

1. The nurse is precepting a newly graduated nurse. What is an example of a statement by the new nurse that demonstrates an accurate understanding of pain?

a. "I had my gall bladder out last year and know exactly how you feel."
b. "Patients with neuropathic pain are at risk for developing depression."
c. "Phantom pain may occur after an amputation; however, it is not real pain."

d. "Visceral pain is caused by muscle pain."

2. A patient complains of having experienced back pain for the past two months. The pain is described as sharp, achy, and throbbing that comes and goes. What type of pain is the patient experiencing?
   a. acute, nociceptive
   b. acute, neuropathic
   c. chronic, nociceptive
   d. chronic, neuropathic

3. The nurse is caring for a patient who complains of lower back pain following a kidney infection. What type of pain is the patient experiencing?
   a. breakthrough pain
   b. referred pain
   c. nociceptive pain
   d. phantom pain

4. The nurse is caring for an 8-year-old male who rates his pain as 7/10 on the numerical rating scale. The patient is laughing, playing video games, and showing no physical signs of pain. What is the priority intervention to assess the patient's pain?
   a. Ask clarifying questions to further assess the patient's pain.
   b. Assess the patient's vital signs.
   c. Leave the patient alone to continue playing video games.
   d. Turn the video game off and instruct the patient to rest.

5. The nurse is caring for a patient with Alzheimer disease who has a broken bone. What pain assessment scale is most appropriate for evaluating the patient's pain?
   a. FACES scale
   b. FLACC scale
   c. numerical rating scale
   d. PAINAD scale

6. The nurse is precepting a newly graduated nurse. What is an example of a statement by the new graduate nurse that warrants further education?
   a. "Pain should be reassessed and addressed with additional interventions until the patient's pain goal is reached."
   b. "The numerical rating scale should be used with young children due to its simplicity."
   c. "The FLACC scale assesses five criteria: face, legs, activity, cry, and consolability."
   d. "The FACES scale is not always reliable and should be used in combination with additional pain assessments."

7. The nurse is assessing a patient's pain. What is the most reliable factor for determining if the patient is in pain?
   a. physical signs, such as clinched teeth and grimacing
   b. a history of recent illness or injury
   c. altered vital signs
   d. the patient's own reports of being in pain

8. What pain medications should a patient with liver failure avoid taking?
   a. acetaminophen
   b. hydrocodone
   c. ketorolac
   d. NSAIDs

9. The nurse is educating a patient on the use of a PCA. What statement made by the patient indicates the nurse's teaching was effective?
    a. "I will not need any other pain medications while I am on the PCA."
    b. "I can self-administer the pain medications as often as I need to."
    c. "I can have my spouse push the button if I am asleep."
    d. "The pump is programmed to keep me from getting too much pain medication."

10. The nurse is caring for a patient experiencing postsurgical abdominal pain. What information is important to tell the patient about effective pain management?
    a. "Nonopioids alone will be able to effectively manage your pain."
    b. "To prevent overdose, wait until your pain is moderate before taking pain medications."
    c. "Take pain medications after walking to decrease the risk of falling."
    d. "We will work together to create a regular schedule for pain medication administration."

11. The nurse is considering potential nonpharmacological interventions to manage a patient's pain. What statement demonstrates an accurate understanding of nonpharmacological pain management?
    a. "Producers of dietary supplements must demonstrate their safety and efficacy."
    b. "Reiki applies massage to specific pressure points in the hands and feet."
    c. "Patients should remove clothing before applying heat therapy."
    d. "Tai chi promotes relaxation through body movement and controlled breathing."

12. The nurse is caring for a patient who is in labor. The patient refuses pain medications and wants to control the pain using nonpharmacological interventions. What nonpharmacological intervention would be appropriate for the patient to consider?
    a. acupuncture
    b. herbal supplements
    c. guided imagery
    d. TENS therapy

13. What is an example of a statement that demonstrates an accurate understanding of treating pain for those with SUDs?
    a. "Opioids should never be prescribed to patients with an SUD."
    b. "Treating the patient's pain will resolve the SUD."
    c. "The SUD and the cause of the pain should be treated independently."
    d. "The pain will be resolved once the patient completes rehab."

14. The nurse is monitoring a patient for signs of withdrawal. What symptom is associated with withdrawal?
    a. increased appetite
    b. increased energy
    c. constricted pupils
    d. yawning

Check Your Understanding Questions

1. Describe the physiological process that causes pain.
2. What is referred pain?
3. Within what time frame should pain be reassessed?
4. What are adjuvant medications?
5. According to the WHO pain ladder, what types of medications are intended for mild pain? moderate pain? severe pain?
6. Why would a massage not be recommended for someone on warfarin?

Reflection Questions

1. Why does pain potentially alter vital signs?
2. What would you do if data from the pain scale and physical assessment are not aligned for a patient?
3. What is the difference between dependence, tolerance, SUD, and addiction?

What Should the Nurse Do?

The nurse is caring for a 67-year-old female on postoperative day one following an abdominal hysterectomy. The patient appears in physical distress and reports her pain to be 10/10 using the numerical scale. The patient declines pain medication for fear of "becoming addicted."

1. What should the nurse do?
2. What are some possible nonpharmacological pain interventions that could be implemented?
3. What are the risks of ineffective pain management?

Competency-Based Assessments

1. Test your ability to state by memory the steps of how to conduct a comprehensive pain assessment.
2. Write an outline for how you would educate a patient on PCA therapy.
3. Identify three nonpharmacological interventions that may be used to manage pain and write a script for how you would educate a patient on the interventions.
4. Create an infographic to educate patients about prevention of SUDs.

CHAPTER 8
Stress and Stress-Related Disorders

FIGURE 8.1 People, and especially nurses, are often exposed to emotionally charged situations, long working hours, high workloads, and the need to manage complex medical conditions. As a result, they experience various sources of stress that can affect their physical and mental well-being. (credit: modification of "Stressed?" by aaayyymm eeelectriik/Flickr, CC-BY 2.0)

CHAPTER OUTLINE

INTRODUCTION Stress. For most people, stress can come from all aspects of life—disagreements with friends or

loved ones, deadlines at school or work, illnesses, obligations to a team or community—any situation that involves uncertainty and the potential for a negative outcome can stress out the people involved.

Of course, the experience of being a nursing student, however rewarding it may ultimately be, can also cause great stress. Often the complicated process necessary to be accepted into nursing school, from completing applications and interviews to securing finances and basic logistics, is very stressful. And once classes begin, there are books to read, tests to pass, reports to write, and, most importantly, people to help. As a nursing student, you'll learn about the causes of stress and the physiological responses to it, and information that will help you better manage your own stress and assist your future patients as they adapt and heal after illnesses and injuries. Knowing about the physical and emotional components of stress can help you be a more effective nurse.

8.1 Homeostasis, Stress, and Adaptation

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define homeostasis as it relates to stress.
- Identify fundamental concepts of stress.
- Identify and explain fundamental concepts of adaptation.

The human body has a remarkable ability to adapt. It is dynamic and ever-changing as it responds to internal and external stimuli and triggers in the environment. These stimuli may be the malfunction of a body system or organ, or an external factor such as a job loss or death of a family member.

Many body systems work together to maintain stability. When one malfunctions, stress is created on other systems. As a nurse, it is important to understand the relationships between these systems.

Fundamental Concepts of Homeostasis

The process of adjusting to the environment as conditions change, either suddenly or over time, is called **adaptation**. Through these adjustments, the body attempts to keep all its systems in a state of balance, or **homeostasis**, that is conducive to life (Venes, 2017). To maintain homeostasis, the body relies on biological, chemical, and fluid processes that occur autonomically in response to change (Venes, 2017). When the body cannot maintain homeostasis, it experiences illness or disease, and, eventually, death. Even when injury, illness, or disease is present, the body still attempts to find balance. It uses all its systems to regain that balance until it either overcomes the injury or illness or perishes.

An example of homeostasis is the body's attempt to regulate its temperature within the normal range so all cells, tissues, and systems can optimally perform their normal functions. The body is like a thermostat set to maintain an ideal temperature in a house. When the temperature rises, the air conditioner turns on to cool off the house; if the house cools below the established set point, the heater turns on until the air is sufficiently warm. Similarly, if the body overheats, it may generate perspiration to cool down; if its temperature drops too low, the body may begin shivering to generate sufficient heat.

Body Systems and their Effects on Homeostasis

Although body systems may seem like segmented pieces of the whole body, they are completely interdependent and respond to each other in a holistic manner through the process of adaptation. For example, the respiratory and renal systems interact to keep the blood pH in the normal range of 7.35 to 7.45. Carbon dioxide, which affects the acid level in the blood, is controlled by the respiratory system, whereas bicarbonate, which controls alkalinity, is controlled by the kidneys. The lungs may breathe faster or slower to exhale or retain carbon dioxide, and the kidneys may excrete or hold onto bicarbonate in respnse; the perfect interplay of these systems helps maintain homeostasis, allowing optimal functioning of the blood as it courses through the body.

Each body system performs its own inherent functions but, at the same time, affects other systems. The brain is known as the master controller for the entire body, but there are many backup systems throughout the body to help. For example, the medulla oblongata in the brainstem helps control vital signs such as breathing, pulse, temperature, and respiratory rate; the carotid arteries and the kidneys contain chemoreceptors (which measure chemicals) and baroreceptors (which measure pressure) to help regulate blood pressure. Table 8.1 briefly summarizes the main functions of different body parts and systems in maintaining homeostasis.

Body System	Function
Brain	Responds to emotions, sensory input, and internal and environmental triggers
Integumentary	Controls body temperature, absorbs vitamin D, stores hormones, and protects the body from external damage
Respiratory	Controls respiratory rate and the exchange of oxygen and carbon dioxide
Cardiovascular	Controls blood pressure and volume, and transports essential nutrients, gases, electrolytes, and hormones to the various cells within the body
Gastrointestinal	Transports, digests, absorbs, and excretes nutrients
Musculoskeletal	Enables body movement and creates blood elements
Renal	Filters, reabsorbs, and excretes fluids and electrolytes
Reproductive	Creates and maintains sex hormones and physical sex characteristics
Endocrine	Responds to changes in body chemistry through positive and negative feedback by increasing or decreasing hormones
Hematopoietic	Stimulates red blood cells, white blood cells, and platelets in the blood
Immune	Responds to antigens and activates the body's immune response

TABLE 8.1 Control of Homeostasis

Although there are medical specialists who focus on just one body system, such as cardiologists for the heart or endocrinologists for hormones, nurses practice with a holistic approach to client health. In your practice, you will need to understand the processes that each system uses to maintain homeostasis. Therefore, each system and its main disorders will be explored in greater detail in later chapters of this textbook.

Fundamental Concepts of Stress

We define **stress** as any disruption to the body's normal state. It can be physical, biological, emotional, or psychological. Stress exists from the moment a person is born, as the baby feels the stress of leaving the comfort and warmth of their mother's womb and entering a cold, unfamiliar world. Because stress is universal, it is considered a normal physiological process as the body adjusts to change and attempts to restore homeostasis. Some stress actually triggers the body to breathe, since the atmospheric air pressure around us is not the same as the pressure in our lungs. The difference in air pressure puts stress on the body, causing the diaphragm to contract. This, in turn, makes our chest expand, and we inhale through our nose, mouth, trachea, bronchioles, and alveoli.

As this example shows, stress can have positive effects. A **positive stress** is when a stressful event produces healthful outcomes such as breathing, which provides us the oxygen our bodies need to live. The stress of exercise is also positive, resulting in increased muscle strength and cardiovascular health. However, most people probably associate stress mainly with negative effects. A **negative stress**, also called distress, is when a stressful event produces unhealthful outcomes, such as illness or disease (Lazarus & Folkman, 1984).

Stressors

A **stressor** is an event or stimulus that activates an individual's stress response (Centre for Studies on Human Stress, n.d.). Even though all people experience stress, the experience itself is highly individualized and varies from one person to another. Several factors affect a person's response to a stressor, including their physical and emotional states. A person's intellectual understanding of a stressor also matters. Under most circumstances, a

person may be able to handle an exposure to a seasonal virus. Their body quickly fights off the infection, and they experience few, if any, symptoms of illness. However, suppose they encounter the same virus during a physically or emotionally challenging time. A person may struggle to fight off a virus if there are additional stressors taxing the immune system. For example, if the person lost a job or is not getting adequate sleep or nutrition, the body may be weaker against a physical stressor such as a virus. This example explains why someone who is already sick generally should not be given a vaccine: their body is in a weakened state and may struggle to adapt to additional stressors.

In a recent poll, 73 percent of respondents identified financial concerns as their primary stressor (White, 2023). Some other common stressors people experience include environmental stressors (e.g., living environment; politics); lifestyle stressors (e.g., work; relationships; recreational choices); major life event stressors (e.g., childbirth; marriage; death; new job); organizational stressors (e.g., daily routines or lack thereof); physiological stressors (e.g., pregnancy, illness).

REAL RN STORIES

Nurse: AJ
Setting: Intensive Care Unit
Location: Las Vegas, NV

During the worldwide COVID-19 pandemic, many nurses experienced levels of stress they had never experienced before. Nurses work in stressful environments ordinarily, but they have been trained to adapt as they focus on helping their clients. What was unexpected during the pandemic were the emotional and physical stressors caused by higher patient loads, lack of personal protective equipment, lack of control in their environment, and the anxiety and fear of bringing the deadly virus home to their own loved ones.

"I thought I was a good nurse, but the COVID-19 pandemic pushed me and my nursing team to new lows," says AJ. "We worked despite our own fears as we saw the fear in the faces of our own patients restricted to isolation away from their families while they were intubated and dying. I have never been so stressed out before in my life. We soon realized we had to apply all those stress reduction strategies we learned in nursing school to ourselves, and it helped."

Fundamental Concepts of Adaptation

A crucial part of adaptation is the ability to cope with stressors to decrease negative stress. A person's coping ability depends on multiple variables, including their mental and physical abilities (Segerstrom & Miller, 2017).

Behavioral approaches to coping with stress are called **adaptive behaviors**. There are two opposite approaches: positive adaptive behaviors and **maladaptive behaviors**. Both may reduce stress, but **maladaptive coping** creates additional negative outcomes. An example is dealing with emotional stress by overusing alcohol, which may result in social distress, financial problems, and alcoholism leading to physical illness. Other maladaptive behaviors include pulling out one's hair and cutting oneself; again, these behaviors may relieve stress in the short term but they cause physical harm to the stressed individual and are often signs of underlying psychological problems.

Nurses are in a position to assess adaptation to stress in their patients and educate them on positive adaptive behaviors. For example, a nurse might teach a patient with chronic obstructive pulmonary disease to use pursed-lip breathing to release more carbon dioxide trapped in the lungs.

Stress Adaptation Model

The **Stress Adaptation Model** is based on the work of Dr. Hans Seyle, who declared that stress affects overall health. According to Seyle, stress and health are biochemically linked, and chronic stress creates physiological illness when the endocrine system is exhausted. He recognized similar responses by all people when they perceived stress, thus he named it the General Adaptation Syndrome (Selye, 1965). He recognized that when an event is new, unpredictable, a threat to self, or creates a sense of lack of control for the person, the individual will experience stress. The response by any individual experiencing stress passes through three stages: (1) the alarm reaction, (2) resistance, and (3) exhaustion if the stressor continues unresolved. Each of these will be explored in more detail,

because nurses must be able to assess physical and emotional responses to stress in their patients.

8.2 Causes and Types of Stress

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define stress and stressors
- Identify physical, physiological, and psychological stressors
- Differentiate between internal and external stressors
- Distinguish between acute and chronic stressors

Stress is a normal part of life. Nurses need to understand the types of stressors, how people define stress, and how to distinguish between internal, external, acute, and chronic stressors for their patients. They must apply concepts of stress management to help patients and their families, as well as to help themselves.

Dimension of Stress and Stressors

Recall that different people may experience the same stressor in different ways and that an individual's experience of a stressor is influenced by a variety of physical, psychological, and emotional factors. Furthermore, people experience stress along a continuum, ranging from mildly stressful events to severely alarming or even life-threatening ones. A familiar mild stressor is an alarm clock in the morning: the sound disrupts our sleep, waking us up and forcing us out of bed. At the other extreme of the stress continuum, consider a car accident that leaves the driver pinned beneath a vehicle and a loved one looking on. The stress resulting from such an event can cause surprising physical changes. For example, the onlooker may experience a temporary surge of strength that allows them to lift the car off their loved one.

The stress continuum encompasses responses to many types of stressors, which may be categorized in different ways: internal or external, physical or psychosocial, acute or chronic (National Institute of Mental Health, 2023). An **acute stress** is short term, compared with **chronic stress**, which lasts longer than several months. Internal stress may be caused by a physical disorder within the body in contrast to an external stress outside the body. A **physical stress** can affect the body both internally and externally. A psychosocial stress is generally a disruption in the person's mental health and well-being.

Internal and External Stressors

Recall that a stressor is an event or stimulus that activates an individual's stress response. A stressor may come from within or outside of the body. Internal stressors generally come from a person's mental interpretation of an event or stimulus, and they can vary largely among people depending on their age, sex, experience, values, cultural and religious beliefs, and even resources available to deal with the stressor. Consider how two nursing students might respond to an upcoming exam. One student might feel a lot of anxiety and have difficulty studying, whereas another student might approach the exam confidently as one step closer to graduating as a nurse. The stressor is the same, but the individual's interpretation of it can create a negative experience for one student compared with an energizing experience for the other student.

External stressors are events and circumstances that come from outside sources rather than mental or emotional processes. A common example of an external stressor that nurses see in their patients is the physical stress of an infection or injury. Another example is a full bladder that the patient cannot empty on their own. Regardless of the stressor, nurses focus on eliminating and treating it through medication administration and nursing interventions. In the case of an illness, this might involve antibiotics or surgery; in the case of a full bladder, the nurse might place a urinary catheter in the patient.

Physical and Psychosocial Stressors

Physical stress involves measurable disruption to the body, and it is often the focus of many patients whom nurses see in medical clinics or hospitals. Physical stress may be due to factors such as infections, trauma, and external exposure to pathogens. A large percentage of the work nurses do is to care for the physical needs of patients as medical providers prescribe the plan of medical treatment for physical stressors.

It is important for the nurse to recognize physical manifestations of stress, which include activation of the **sympathetic nervous system**, which controls many automatic body functions, such as heart rate, blood pressure,

and perspiration.

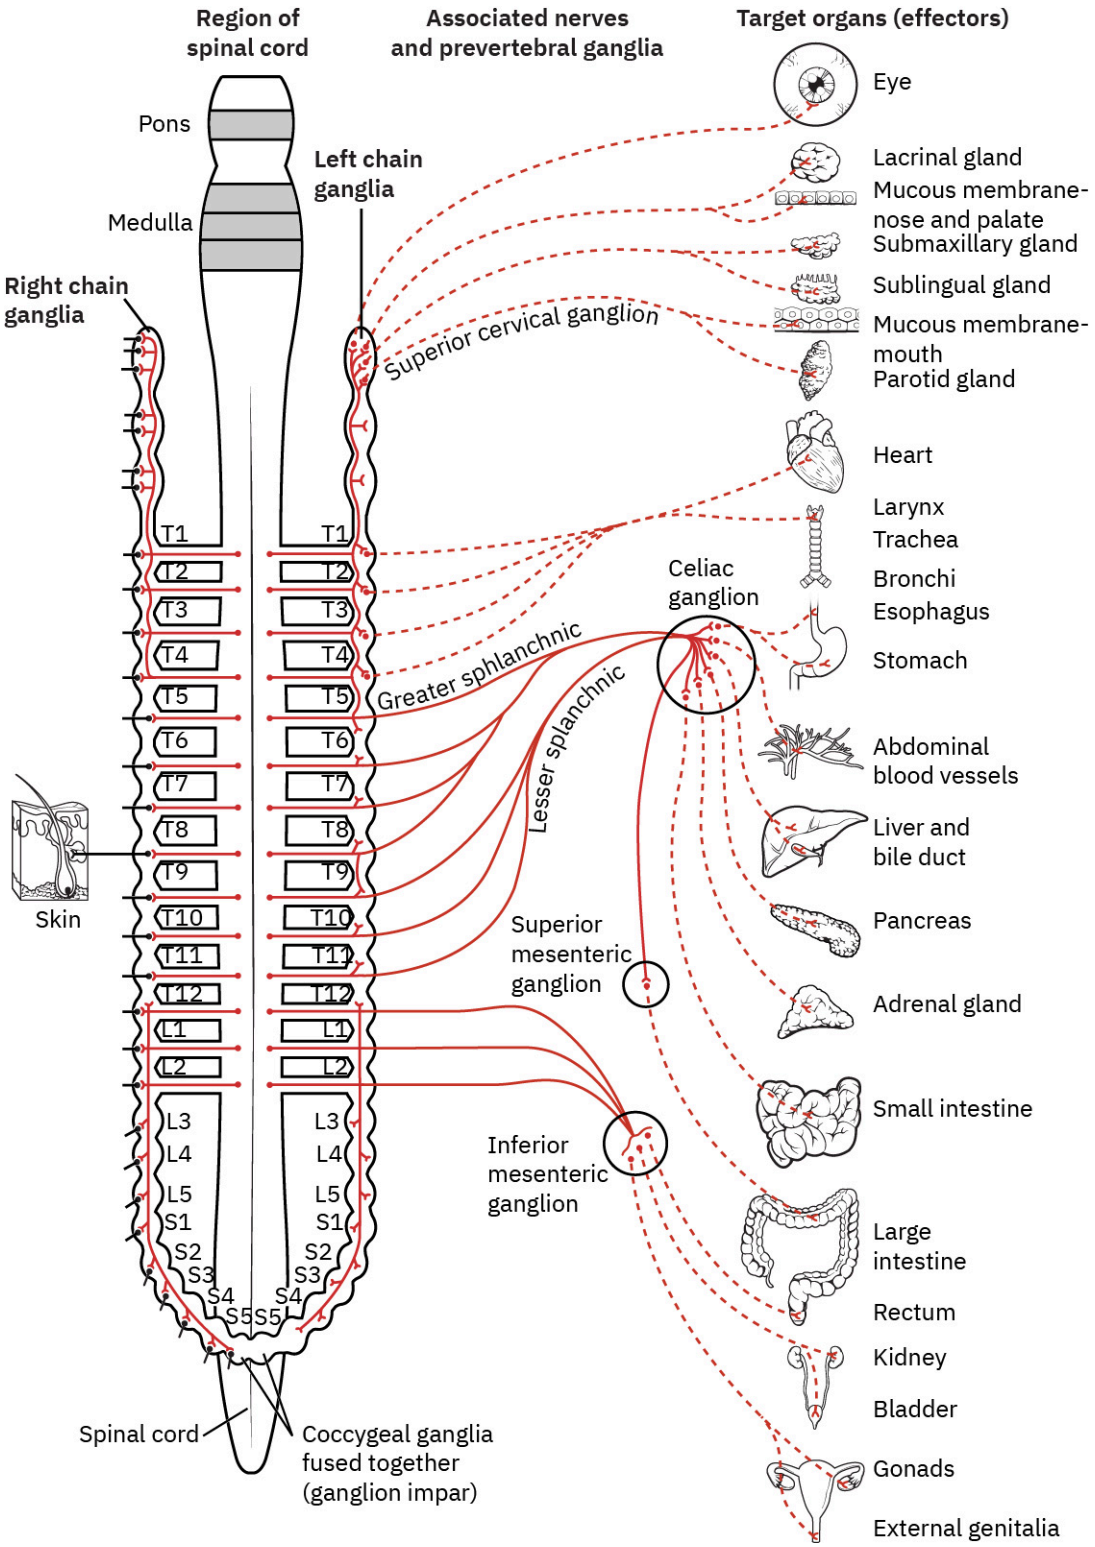

FIGURE 8.2 Activation of the sympathetic nervous system during stress can affect several body organs. Psychological and psychosocial stressors can also manifest in physical signs and symptoms of stress. As a nurse completes a head-to-toe assessment, each body system can manifest signs and symptoms when the person is under stress. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Physical stress includes any external or internal condition that disrupts normal cellular function, such as temperature change, poor nutrition, hemorrhage, or dehydration (Freedland et al., 2023). The disruption produces

physical manifestations as the body attempts to restore homeostasis. An interesting example is a condition seen in patients with spinal cord injury patients: **autonomic dysreflexia**, in which the body tries to rid itself of a stressor that the brain cannot recognize (McCarty, 2016).

LINK TO LEARNING

Watch this video to learn more about causes and effects of autonomic dysreflexia (https://openstax.org/r/77dysreflexia) as well as assessments and interventions.

The mental and emotional response to stress is referred to as **psychosocial stress**. For example, consider how two people may respond to the loss of a job. For some people, a layoff or getting fired is viewed as a personal failure. They may lose confidence in themselves and even develop symptoms of depression. Over time, these deep emotions can lead to physical distress. But for someone else, losing a job can be a "blessing in disguise" that gives them the opportunity to follow a different path, perhaps pursuing a dream career or going back to school. In both situations, the external stressor is the same—it's the personal interpretation and experience of psychosocial stress that make the difference.

Factors that influence psychosocial stress include age, gender, culture, religion, family support, and access to economic resources. For example, an event that causes an adult great stress, such as a family reunion, may not bother a child, who does not realize the event's significance. Stress that is devastating to someone with a certain cultural background may not affect someone with a different background. The sound of a shotgun may be distressful to a member of the military who has experienced warfare, because the sound may trigger symptoms of post-traumatic stress disorder (PTSD); however, members of the general public may mistake a gunshot for an unthreatening popping sound, like the backfire of a car exhaust, and scarcely notice.

LIFE-STAGE CONTEXT

Effects of Age on Stress

An individual's response to a stressful event includes the important variables of gender, culture, and age. Children, for example, are at increased risk for stress because their coping skills may be underdeveloped. They may not have the vocabulary or understanding of their own feelings to be able to express and explain their stressors. Children may also not be able to regulate their emotions and may react impulsively because they have not developed coping skills. However, children are generally resilient and adaptable, especially with support from caregivers.

Older adults are at increased risk for stress due to cognitive changes that may lead to slower processing or memory issues. Although stress may make these cognitive challenges worse, their life experiences may help them deal with stressful situations. Health problems may increase an older adult's stress but may also affect their ability to remain independent, which can further increase stress and thereby exacerbate health problems. Declining mobility and physical health can make adapting to stress more difficult.

Although stress can affect children and older adults in different ways, the nurse can encourage patients of all ages to establish or rely on an existing support system to help improve their abilities to cope.

Acute and Chronic Stressors

In medicine, the terms acute and chronic are used to describe the time frame of symptoms or conditions. Stressors that generally appear suddenly and may cause severe distress, but whose symptoms may last only several minutes, hours, or days are **acute stressors**. For example, someone working outside in the heat may begin to become dehydrated, but they can relieve this stress by cooling off and drinking water. On the other hand, **chronic stressors** are long-term experiences; they produce symptoms that may last weeks, months, or even years. For example, a stroke may leave a person with hemiparesis (one-sided paralysis) that lingers for years.

Sometimes acute and chronic stressors can occur at the same time. For instance, someone who is struggling with a chronic condition of cancer may have an acute stress after breaking an arm or developing a viral sinus infection. A careful nursing assessment includes the ability to assess and treat both kinds of stress. If an acute stress is not

treated effectively and in a timely manner, it may progress to become a chronic condition (e.g., an untreated foot infection may progress to gangrene).

8.3 Stress and Disease

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss stress as a response
- Define stress as a transaction
- Identify how stress acts as a stimulus for disease
- Provide examples of disease processes where stress was a stimulus

Stress is a dynamic process, which means it changes and is influenced by various factors. It is the characteristic response to stressors or stimuli, and if not responded to in a healthy manner, can lead to disease. Nurses need to recognize the clinical manifestations of stress as a response to stressors and the variation in our responses to stress. How we respond to stress depends on many factors, and this known as the transactional model of stress. If the response to stress is negative and does not allow a return to homeostasis, disease may occur.

Stress as a Response

Stress is generally considered an event or factor that acts on a person, but it can be both the stimulus itself and the cluster of clinical manifestations experienced as a result of the stress (MedlinePlus, 2022). For example, a patient may experience stress from an illness but then demonstrate manifestations of the response to stress as hypertension, tachycardia, diaphoresis, and other sympathetic system responses. Stress can be a response to a stressor (the stress response). When a patient is exposed to an external stressor such as a pathogen, the body responds with the inflammatory response, which stresses the body toward recovery to fight the infection. The response itself may cause disease if it does not help the body recover homeostasis.

Stress as a Transaction

The **Stress Transactional Model**, originated by psychologists Lazarus and Folkman (1984) and shown in Figure 8.3, states the response to stress as a transaction considers the various factors that affect a person's response to stress. These factors include those that are personal, social, environmental, spiritual, and cultural, as well as emotional intelligence level and even educational level. An example of the variation among responses based on the transaction of these factors could be the difference between two people who spill a cup of juice. One person may consider it an annoyance and then clean it up and move forward in their day, whereas another person may become very upset and let the event destroy the entire day. The factors that came into play for the different responses may have been the age, sex, emotional level, and even the economic level of the two individuals. These are the factors that need to be considered by nurses when assessing stress levels and responses of their patients.

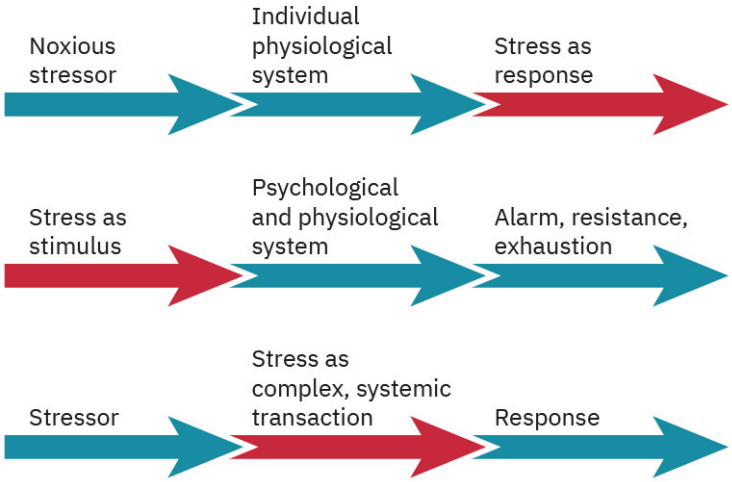

FIGURE 8.3 The Stress Transactional Model considers the effects of personal, social, environmental, spiritual, and cultural factors, as well as emotional intelligence level and even educational level as factors that affect a person's response to stress. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Stress as a Stimulus for Disease

Stress is a very common factor that leads to disease. Disease is defined as a disorder of the structure or function of the body (Merriam-Webster Dictionary, 2022). A stressor often contributes to the disorder of normal function. When homeostasis is disrupted, the body will either respond in a healthy manner to recover from the stressor, or not. For example, when a body builder stresses muscles with heavy weights and exercise, the muscle tissues may be broken down by the stress, leading to weakness. However, when the body can recover and rebuild the torn muscle, the result is a stronger and bigger muscle. When the body cannot recover and adapt to a stressor, it may further deteriorate, and result in disease.

Stress can then be a stimulus toward disease. For example, when a person is confronted by antigens and pathogens, the stress response results in efforts to protect the body. The stress can create disease if the body is unable to fight it. An extreme example is when a patient first encounters a pathogen: without successful recovery, infection by the pathogen may lead to a further stressor known as sepsis. Conditions that correlate stress-related disorders and disease include the following (Fulda et al., 2010):

- acne
- Alzheimer disease
- anxiety disorders
- asthma
- autoimmune disorders
- back and neck pain
- cardiac dysrhythmias
- coronary heart disease
- depression, anxiety, and panic attacks
- diabetes
- dysmenorrhea
- dyspepsia (indigestion)
- eating disorders
- eczema
- erectile dysfunction
- fatigue
- fibromyalgia
- headaches
- hypertension
- immunodeficiency
- insomnia
- irritable bowel syndrome and other gastrointestinal symptoms
- insomnia and sleep disturbances
- obesity
- poor wound healing
- stroke

8.4 Physiological Response

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Understand the brain's physiological adaptation and response to stress
- Differentiate the sympathetic versus parasympathetic nervous system response
- Explain the theory of adaptation
- Discuss the nurse's role in identifying indicators of stress in a patient

The physiological response to stress includes each body system's attempt to adapt to stressors. Activation of the sympathetic nervous system is the hallmark response to stress. Involvement of all body systems when the sympathetic nervous system is activated is the goal of adapting to the stressor. The nurse plays an important role in identifying factors that contribute to stress, the patient's response to stress, and intervening to help restore balance

to the patient.

Physiological Adaptation and Response

The body's key adaptation response to stress is activation of the sympathetic nervous system, known as the fight-flight-freeze system. It activates all body systems to be prepared to fight or flee against the stressor. The classic scenario is a threat of attack, so the body is primed for defense. Muscles are tensed, pupils are dilated to see wide and clearly, lungs are open to suck in all oxygen possible, and blood is shunted away from the gut so it can be sent to the brain and muscles. In completing a physical examination of a patient in stress, many hallmark clinical manifestations will reveal activation of the sympathetic nervous system. This stress response is useful for acute and immediate stress but is not meant for chronic stress. The wear and tear of the body in constant stress exhausts the body and may end in collapse.

Patients who are chronically stressed with work or life's demands may find their other body systems become depleted as hormones and chemicals being exchanged in the hypothalamus and pituitary initiate the stress response throughout the body (Welt, 2023). For example, the body of a person with untreated sleep apnea is chronically stressed due to the lack of adequate oxygen during sleep. As a result, the patient is always in fight-or-flight mode, even when at rest. Some conditions that could easily be managed can be exacerbated by chronic stress as the body diminishes its resources and ability to adapt. Many times, this is the condition in which nurses see patients: their body's ability to adapt has decreased.

Interpretation by the Brain

The human mind responds to signals and messages that are sent through various hormones and chemicals, all trying to maintain or restore balance in the brain. The complex process responds to perceived stress or threats with a sympathetic fight, flight, or freeze behavior—even if the threat is actually quite irrational. This is why a person may know, logically, that it is extremely unlikely that the elevator they are riding in will crash, yet they still experience full-blown panic attacks at the mere suggestion of taking the elevator in their building. In those moments, they will feel the rush of rising blood pressure, their heart will race, they will feel as though they cannot catch their breath—they may hyperventilate. This response looks and feels as though the body is getting ready to defend itself or flee from some major attack. And the brain interprets that stress as a threat and responds as it should, even if the treat is not much of an actual threat at all in reality.

Cognitive behavior therapy and other psychotherapies focus on controlling the brain's interpretation of stressful events by controlling thoughts. Nurses can help decrease a patient's sympathetic response by role modeling breathing techniques and reorienting the patient to reality.

Sympathetic Nervous System Response

The sympathetic nervous system is part of the autonomic, or involuntary, system that affects organs, in opposition to the **parasympathetic nervous system** (Figure 8.4). Whereas the parasympathetic system is known as the "rest and digest" or "feed and breed" response, the sympathetic system is primed for fight-flight-freeze activities for the body under stress. The common phrase "fight or flight" was altered in 2015, with "freeze" added as a possible response after studying the impacts of traumatic and adverse events on sexual assault victims, plane or car crash victims, soldiers who had been in battle, and people attacked by animals. (Kozlowska et al., 2015). They could neither fight nor flee and literally became immobile (frozen) with fear.

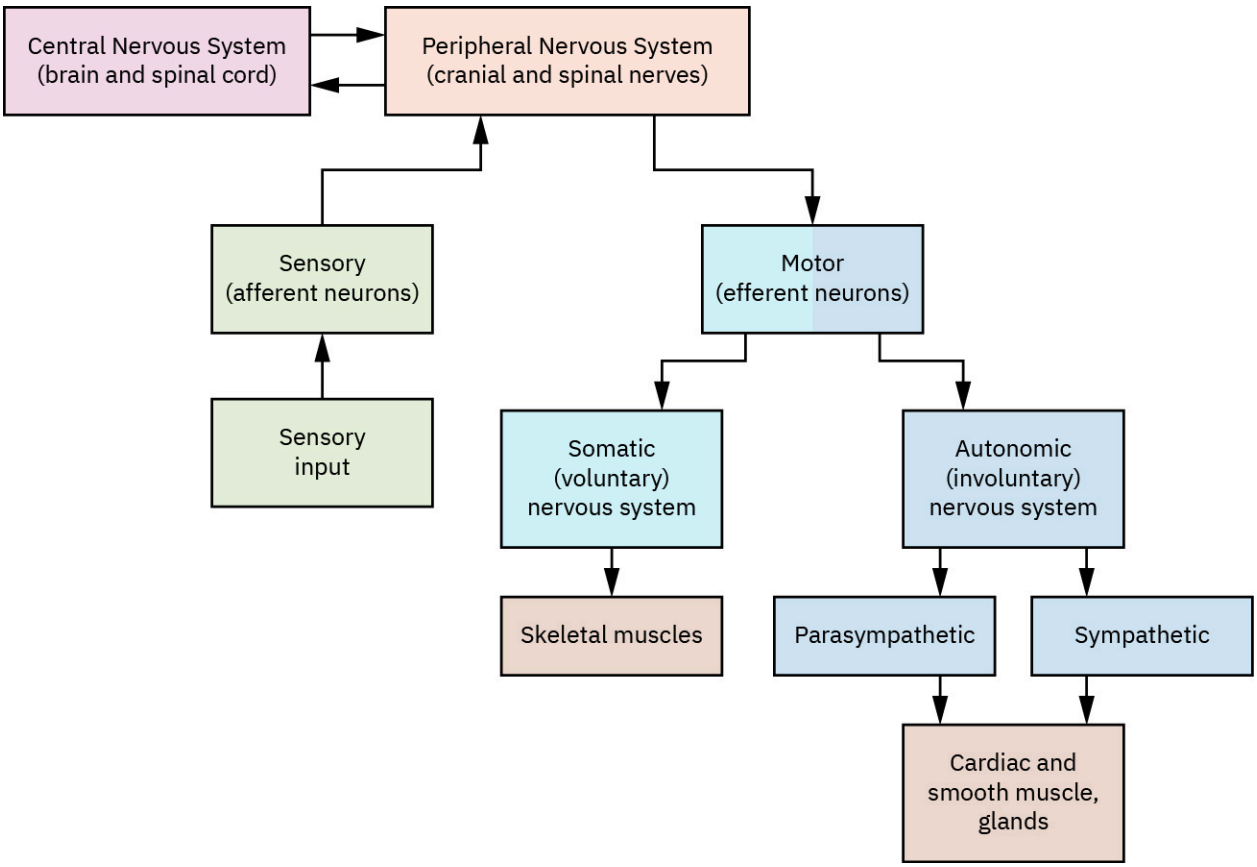

FIGURE 8.4 The sympathetic and parasympathetic nervous systems are parts of the autonomic nervous system. They regulate the functioning of glands and cardiac and smooth muscle. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The sympathetic nervous system activates body organs to prepare for a response to an assault. Pupils dilate, muscles become tense and engorged with needed oxygen rich blood, glucose levels are elevated by the adrenal glands and liver for energy, lungs and airways dilate, and blood from the gastrointestinal system is shunted to more vital organs. The result is elevated blood pressure to support activity to fight the stressor. If the sympathetic nervous system remains activated for a long time, it results in constipation, chronic hyperglycemia, decreased immune response, and overall body fatigue. People with chronic stress, therefore, may develop chronic disease such as hypertension, hyperglycemia, poor nutritional absorption, and ulcers (Sheng et al., 2021).

Recognize that medications and substances can trigger a sympathomimetic response, such as caffeine consumption and cocaine. Excessive use of these substances can create stress on the heart. Some medications are used purposefully to stimulate the sympathetic response (also called adrenergic response), such as medications used for a nonstress test or epinephrine used to treat a cardiac arrest.

Hypothalamic-Pituitary Axis Response

A complex system that helps the brain respond to stress is the **hypothalamic-pituitary axis (HPA)**. Through a neuroendocrine mechanism, messages from hormones in the blood (the endocrine component) and the nervous system (the neurological component) pass through the hypothalamus and pituitary gland in the brain. These messages are mediated by the brain to regulate metabolism, the immune response, body temperature, body fluids balance, and the **autonomic nervous system**. Known as the control center for hormones, the hypothalamus receives messages from the body's organs and then sends signals to the pituitary. The pituitary, which is further divided into anterior and posterior compartments, emits the appropriate hormones to the body to respond to internal and external environmental signals (Welt, 2023).

One key hormone that is activated by the HPA is glucocorticoid-releasing factor, which, in turn, stimulates the adrenal cortex to release cortisol and other glucocorticoids. A main function of **cortisol**, also known as the stress hormone, is to elevate the blood glucose level; glucose is needed to supply muscles for the flight-fight-freeze response of stress. Short-term elevation of the cortisol level allows the body to have the energy it needs; however,

long-term release of cortisol can create chronic hyperglycemia and its associated complications.

Sympathetic-Adrenal-Medullary Response

In response to chemical and hormonal signals from the HPA, the adrenal glands, which sit on top of each kidney, create, and excrete chemicals known as catecholamines that respond to the sympathetic nervous system. Commonly known as adrenaline, the adrenal medulla makes epinephrine and norepinephrine, which activate sympathetic nervous system responses, including tachycardia and vasoconstriction, to elevate blood pressure. Additionally, corticosteroids are released from the adrenal cortex on the outer layer of the adrenal glands, which increases blood glucose levels, contributing to the needed energy demands of a sympathetic response. The body is well designed with feedback loops to send signals from organs to the brain and back to respond as needed to regulate homeostasis.

Autonomic Nervous System/Immune Response

Thankfully, the autonomic nervous system does not require conscious activation of any of its functions; it responds automatically. However, some functions can be affected by conscious thought. For example, some people learn to lower their own blood pressure and heart rate by meditating and or using calm breathing techniques. Another system affected by the autonomic system is the immune system, which helps fight antigens and pathogens. An **antigen** is something that generates an antibody response—hence, the term "anti-gen."

In addition to elevating glucose levels, cortisol decreases the function of lymphocytes, one of the types of white blood cells that directly fight pathogens. Therefore, long-term stress can decrease the effectiveness of the immune system and put someone at risk for infection because the body may not be able to fight off infections.

READ THE ELECTRONIC HEALTH RECORD

Uncontrolled Diabetes and Stress

You, the nurse, are reviewing morning laboratory text results of a patient who has been hospitalized for uncontrolled diabetes and is now in diabetic ketoacidosis.

Laboratory Test	Normal Range	Patient's Laboratory Test Values
Fasting glucose, mg/dL	70–100	254
White blood cells, mL	5,000–10,000	15,000
Red blood cells, million/μL	3.8–5.8	5.2
Sodium, mg/dL	135–145	156
Urine ketones	Negative	Present

1. Analyze the patient's laboratory values and explain how each result reflects the physiological response to diabetic ketoacidosis and the stress on the body.
2. Evaluate the significance of the elevated white blood cell count in the context of diabetic ketoacidosis. Discuss potential reasons for the poor response by leukocytes in this patient and the implications for patient care.
3. Prioritize the nursing interventions based on the patient's laboratory results. Discuss which abnormalities require immediate attention and how they contribute to the management of diabetic ketoacidosis.

Theory of Adaptation

Hans Seyle, the founder of Stress Theory, introduced the concept of adaptation in his work on stress. As a physician, he noticed that patients who experienced mental or physical stress and were able to adapt to the stressor in a

positive way were able to recover, whereas those who could not adapt and adjust to a stressor deteriorated.

Medical treatments are used to intervene and help the body adapt, but individual qualities and abilities of each patient influence the success or failure of treatment. For example, a patient who has substance use disorder with alcohol may not have the liver capacity to rebound from a gallbladder attack, because the liver cannot respond correctly under the additional stressor.

General Adaptation Syndrome

The **General Adaptation Syndrome** is a process comprising three distinct physiological stages the body passes through when experiencing stress. As shown in Figure 8.5, the first stage is alarm, followed by resistance, and, finally, exhaustion. First described in a medical journal in 1936, Dr. Seyle identified that when a toxin is introduced into the body, predicted sympathetic nervous system physical responses were seen in laboratory rats and, later, in clinical patients.

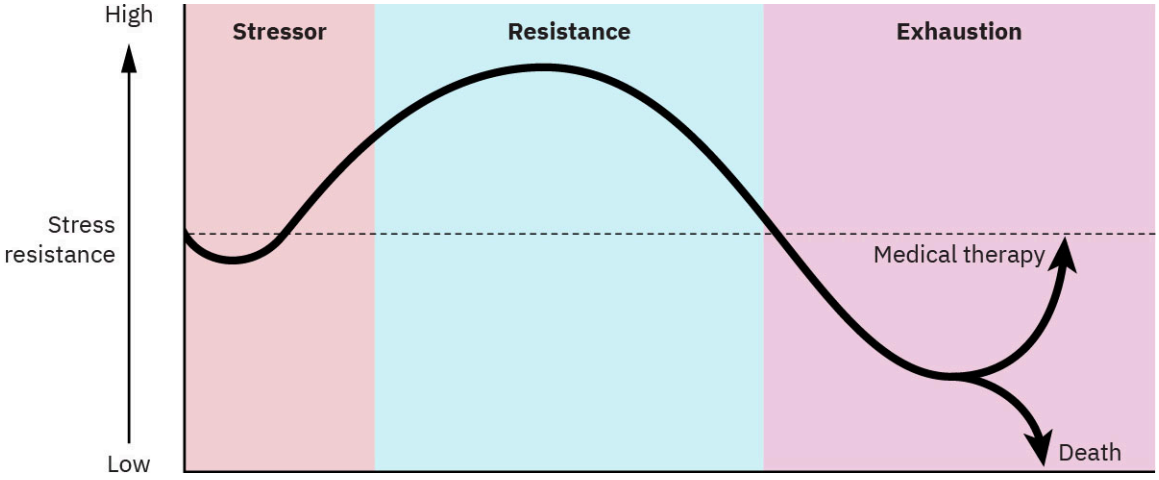

FIGURE 8.5 The three phases of the General Adaptation Syndrome are alarm, resistance, and exhaustion. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The first alarm stage is characterized by the classic sympathetic nervous system responses to ready the body for fight or flight. Dr. Seyle also noticed the increase in corticosteroid levels during the alarm phase, with a resulting decrease in ability to fight the infection. Interestingly, an enlargement of the adrenal glands was also noticed that was due to the increased released of adrenal hormones during the alarm stage. If the stressor continues, yet the body can resist and adapt, these symptoms decline, but if the stressor continues and the body is unable to adapt, the body becomes exhausted. Prolonged exposure to the stressor or toxin can result in exhaustion or death if the body cannot adapt.

Local Adaptation Syndrome

Systemic stress has been discussed; it results in an overall sympathetic response of the body. In contrast, **local adaptation syndrome** is when the body responds only locally to an external stressor such as a wound, which may result in only a local response of the nearby tissues and circulation. The inflammatory response is the first physical response to injury or a pathogen. Blood vessels begin to dilate in an attempt to increase the flow of red and white blood cells and platelets to the area. Ideally, white blood cells will attack the pathogen, red blood cells will deliver needed oxygen to damaged tissue, and the platelets begin their clotting cascade to close off any wound. Depending on the size of the wound, tissues can then move through the healing process. Although the local area may go through the similar alarm, resistance, and exhaustion stages, these occur on a much smaller scale and do not affect blood sugar levels, overall white blood cell decline, or other sympathetic responses.

The concept of local adaptation is important for nurses to understand specifically for wound and tissue healing. Nurses can help tissues heal by improving the patient's nutrition with adequate fluids and protein and also intervening with cold packs, pressure, and elevation to local sites of injury that naturally respond to the stressful injury with tissue swelling from the initial inflammatory response.

Indicators of Stress

One major tool nurses use during a patient assessment is vital signs. Also, a full head-to-toe physical assessment is

required for a nurse to properly provide care for a patient, especially during a stressful event. As outlined previously, each body system can reveal physical signs of stress. For example, hair loss may be due to alopecia or aging but can also be seen in someone who is pulling their hair due to stress. Short, irregular nails can also indicate nervous nail biting. The astute nurse needs to pay attention to signs the body gives regarding stress. The following are physical signs of stress:

- acne
- blurred eyesight or sore eyes
- chest pains
- constipation or diarrhea
- difficulty breathing
- fatigue
- headaches
- high blood pressure
- indigestion or heartburn.
- menstrual cycle changes
- muscle aches
- panic attacks
- picking at nails, skin, or hair
- poor concentration
- sleep problems
- sweating
- teeth grinding
- weight loss or gain

8.5 Psychological Response

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define the appraisal of a stressful event
- Explain how one may cope with a stressful event
- Discuss the effects stress has on one's psychological, behavioral, and cognitive functions

Nurses must recognize the psychological response to stress to better assess, evaluate, and create a care plan to help the patient. Using the clinical judgment measurement model, the nurse can assist the patient who is experiencing a stressful event achieve optimal outcomes.

Appraisal of Stressful Event

Psychological stress is the neurological response to experiencing a stressor or event, and the distress that results when the stress exceeds one's ability to adapt and cope. An important factor in appraising a stressful event is the mental and emotional interpretation of the event. Although the work of Hans Selye outlines a predicated response to stress, more modern research reveals there is still much variation due to differences among people's interpretation of stress.

Evaluating a stressful event first requires asking the person what they find stressful about the event. How someone perceives reality becomes their reality, which may be very different from that of another person. Their cognitive appraisal of the stress matters, even if it appears unreasonable or illogical to another person. Lazarus and Folkman added to the contemporary view of stress and coping with their transactional theory (Lazarus & Folkman, 1984). The ability to adapt to a stress is called **coping**, and is contingent upon the person's view of the level of threat, resources available, and ability to overcome the stress. If there is a match between the threat level and the perceived ability to overcome or address the threat, coping can be effective.

Coping with a Stressful Event

Coping is on a continuum from poor management to successful and effective management of a stress. The concepts of stress and coping apply to individuals, families, and communities. Coping abilities become part of the stressful

experience and can either decrease or worsen the stress. Although humans have great ability to cope, there can be a limitation to what a person can cope with. One stressful event may become a mere nuisance, but when grouped together or in a string of stressful events, however, such a situation may lead to a person's inability to cope effectively. For example, an acute illness such as a cold or pneumonia may become a bother to a person but is very manageable. If that simple event is coupled with inability to pay for medical care, lack of resources to travel to the doctor, and income lost due to missing work, it can become quite difficult and unmanageable. Nurses need to be aware of additional stressors in a patient's life beyond the present chief complaint or reason they are hospitalized, because it is rarely associated with a single event.

Coping may be adaptive or maladaptive (Centre for Studies on Human Stress, n.d.). Adaptive coping is the ability to navigate and manage a stressful event in socially acceptable ways and with positive outcomes. For example, seeking medical attention or psychiatric counseling demonstrates a thoughtful and responsible behavior to address a problem. Maladaptive behaviors do decrease stress but generally produce negative outcomes and may add problems to the situation. An example is someone who drinks alcohol or takes illicit drugs to cope with a poor marriage or loss of a job. The maladaptive behavior does not solve the problem—often it only masks it and can cause additional distress. Even if maladaptive behaviors sound illogical, people still use them because they can decrease initial distress, such as smoking or taking sedatives to numb emotions and problems.

Effects of Stress

Effects of stress can be neutral, positive, or negative. Stress has been shown to initiate and encourage growth, but it can also stunt growth and disable a person. The difference is in the amount, type, and interpretation of that stress, and the person's access to resources. In the role of a nurse, physical and psychological effects of stress must be assessed. The physical examination can help the nurse identify physical and emotional effects of stress, as outlined earlier.

Normal physiological processes are activated by stress and, if coping is intact and resources are available, the stressor becomes neutral. Navigating traffic on your way to work or school can be a neutral stressor. If, however, your car is unreliable, traffic is heavy, and you are late to class, the same stressor of traffic can become negative and cause distress. The same stressful event of navigating traffic could become a positive experience if the ride is shared with someone engaging and the conversations in the car are enjoyable.

The effects or consequences of stress affect all body systems (Abdulkaleq et al., 2018). It is within the scope of the nurse to evaluate the physical and emotional effects of stress.

Psychological Stress

In the medical profession, nurses focus on physical stressors that cause illness or injury; however, psychological and emotional stressors may be more common among the public. According to the results of an American Psychological Association 2022 survey of people in the United States, the most common causes of stress included the future of America (63%), finances (62%), work (61%), politics (57%), violence and crime (51%), and negative racial climate (62%) (American Psychological Association 2022). Worry and stress about life is part of our human daily experience. Psychological signs and symptoms of stress include the following:

- anger and irritability
- anxiety
- depression
- disinterest
- dizziness
- loneliness
- loss of concentration and memory recall
- restlessness
- tension
- sense of dread
- sexual problems
- withdrawnness
- worriedness

Variations in stress and coping are seen across the lifespan for all age groups as their cognitive, physical, and emotional resilience change. Inquiring about the person's interpretation of a stressful event is helpful in identifying where they are emotional and mentally. Taking the time to assess and question a patient about their biggest concern may even reveal their truest concern. For example, a person who is brought to the emergency department after a house fire would be expected to be concerned about their physical belongings and devastation to their home, but when questioned, the biggest concern for the patient may be the safety of their pet cat and not the physical belongings. Efforts could then be made with social services or the fire department to locate the pet.

Behavioral Responses to Stress

Cognitive behavior therapy considers the very real triangular relationship among thoughts, emotions, and behaviors. Thoughts about stressful events create emotions, which, in turn, are the catalyst for behavior. When negative thoughts exist, negative emotions are stirred, including anger, depression, loneliness, and hopelessness, which can lead to maladaptive behaviors. For example, a nursing student experiences an external stressor of failing an exam, which could lead to thoughts of feeling dumb and worthless, which can lead to self-loathing or anger, which could lead to destructive behaviors such as excessive alcohol intake to drown out the negative thoughts or social withdrawal. Negative behaviors can be traced back to negative thoughts and emotions. Challenging negative thoughts is at the core of CBT. When someone is under stress and behaving in ways unlike their usual self, it is generally negative thoughts and emotions about the stressor that create the maladaptive behavior. Negative coping responses include the following:

- aggressive behavior
- chewing one's fingernails
- criticizing oneself (negative self-talk)
- eating too much or too little
- excessive alcohol intake
- illicit drug use
- reckless driving
- self-mutilation (e.g., cutting oneself, pulling hair)
- sleeping excessively
- smoking or chewing tobacco.
- violence toward self or others
- withdrawal from friends or family

Behaviors that are threats to someone's health can reveal the person is under stress. These behaviors include

- arguing
- avoiding tasks
- changes in appetite
- difficulty completing work or tasks
- excessive drug use
- irrational behavior
- irritability
- lack of self-care
- nervous behaviors (e.g., fidgeting, nail biting, pacing)
- not attending school or work as usual
- outbursts of emotions (e.g., anger, crying
- tardiness

Positive behaviors can also be traced back to positive thoughts and emotions. A nurse can help the patient explore

their thoughts about the stressor to identify their reality or falsehood. Ideally, nurses can help the patient see positive sides of a stressor, without being overly optimistic. Strategies to deal with stress in a positive manner are discussed later in this chapter.

Cognitive Effects of Stress

Humans are often more deeply rooted in feeling than in thought, and they tend to be more emotional than logical beings. Stress can make it all the more difficult to think clearly and rationally about a problem. Even when a person is able to rationally determine that a stressor is not one that should, logically, be a source of stress, it does not mean that they will cease to be stressed out about it. Like physical and psychological stresses, the effect of stress on cognitive abilities can be neutral, positive, or negative. An example of positive effects of stress on cognition is the stress nursing students feel when learning new content or with exam deadlines and clinical duties. The positive stress of learning and meeting high expectations can help someone get organized and feel energized as they push themselves to attain higher achievements and abilities. Unfortunately, stress can also create a negative impact on cognition when the stress level is too high and irrational and cloudy thinking results.

High stress levels can have a negative effect on the brain's ability to process information, rationalize it, and make decisions based on it. For example, a patient who has recently been diagnosed with a terminal illness must make decisions about their care as well as consider the needs of their loved ones after their ensuing death. Nurses need to be able to recognize the stress that patients and their family members will be under during a hospitalization. Everyone involved in a patient's care is asked to take in and process a lot of new information and often need to make important decisions about life and death. It can be useful to give patients and family members written materials that give them clear information to guide discussions and decisions. In times of stress, the ability to mentally process is often lacking or lagging. It's ironic, but when the sympathetic nervous system is activated during the first alarm stage of stress, cognition can get a lot sharper. However when stress becomes chronic, cognition starts to decline. Nurses also need to think about the importance of compassion and patience during these critical and challenging times.

Nursing is stressful, too, and one way to help nurses maintain clear cognition when providing quality patient care is following the Quality and Safety Education for Nurses (QSEN) competencies.

CLINICAL SAFETY AND PROCEDURES (QSEN)

QSEN Competency: Patient-Centered Care

Definition: Providing responsive care that respects individual patient preferences, needs, and values and uses those factors for clinical decision-making

Knowledge: Recognizing and appreciating the diverse factors that influence a patient's experience of stress, including cultural, socioeconomic, and environmental factors

Skill: The nurse will

- assess and evaluate physical manifestations of stress in clients.
- educate clients about positive adaptive behaviors for stress adaptation.
- recognize the individuality of a patient's stress response.
- use effective communication techniques to establish rapport and trust with patients.
- use active listening skills to understand the patient's unique stressors and concerns.
- collaborate with the patient to develop personalized stress management plans tailored to their individual needs and preferences.
- provide empathetic support and encouragement to empower patients to cope with stressors effectively.
- continuously reassess and adjust interventions based on the patient's response and evolving needs throughout their health care journey.

8.6 Inflammation: Cellular Response to Stress

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the cellular continuum of function
- Differentiate between the positive and negative cellular feedback responses
- Discuss the types of inflammation and systemic response
- Identify causes of cellular injury
- Discuss the various causes for cellular injury

The body responds to stress at the cellular level, and the responses affect surrounding cells, tissues, organs, systems, and, eventually, the entire body. Understanding the body's cellular response to stress will help the nurse recognize the physical effects and how pharmacological interventions can help.

Cellular Continuum of Function

The cellular stress response is a cascade of chemical and hormonal signals that activate cellular products needed to re-establish homeostasis. One example is the activation of a type of protein called heat-shock protein to respond to changes in temperature, low pH, or low oxygen level (Fulda, 2010). Cells can respond in adaptative ways to stress or even through **apoptosis**, which is cell destruction to eliminate a stressor to the system. The process by which a cell experiences stress by either dying or becoming more resilient depends on various factors, including toxicity of the stressor, cell strength, duration of the stress, and age of the cell, among others.

Each cell in the body is programmed to live a certain length of time and then die; this is known as programmed death (Fulda, 2010). Cells can die by programmed death such as apoptosis, necrosis, or autophagic cell death. The cell recycles select parts of itself, in a process called **autophagy** (self-eating), to maintain cellular balance. An example would be self-destruction of red blood cells after 120 days, when they pass through the spleen and the iron portion is recycled for the next generation of red blood cells. Without apoptosis and autophagy, the body would not be able to clean up degraded cells. The interplay of genetics and environmental factors can affect the timeline of life for the cell. Stress is a large factor in potential early destruction of a cell. Stress on a cell can also create positive outcomes or negative results. Stressing the muscle fiber cells can increase elasticity and strength or tear and break them down, depending on various external factors.

A cell will respond to an initial exposure to a stressor, just as in the Generalized Adaptation Syndrome, with an alarm stage of activation of pathways to survive. However, if resources such as nutrition, oxygen, or fluids are not adequate, the cell will not survive. Initial responses to cellular stress include production of needed proteins to repair damage from a stressor, as in the case of wound injury.

Control of the Steady State

The adaptive ability of a cell will determine its fate after experiencing stress. An example of the impact of various factors upon a cell to adapt is the effect of exercise on the telomeres within a cell. The distinct structures at the end of a strand of a chromosome within the cell are called **telomeres**. They have been likened to the plastic caps at the end of a shoelace. Telomeres have repeated sequences of DNA, and every time the cell divides, the telomeres shorten until they eventually become so short, the cells dies. This reveals one of the ways a cell is programmed to die. Studies show that exercise strengthens the telomeres, extending their lifespan, whereas poor nutrition and stress weaken them (Shammas, 2011). Research on cell death has been conducted regarding cancer and chronic degenerative conditions such as Parkinson's disease and Alzheimer's disease.

Each cell works to maintain homeostasis and balance throughout stress states by adjusting protein and enzyme production and adapting the functions that affect the tissue and the organ comprising the tissue. Control of the steady state is the quest. Biological homeostasis is achieved by establishing an internal stability for the cell and adapting to demands of the external environment. The body accomplishes balance through regulatory processes known as positive and negative feedback.

Positive Feedback

The method the body uses to enhance a desired outcome by amplifying chemical or hormonal messages to the organs of influence is called **positive feedback**. An example of positive feedback is seen during labor and delivery.

The release of oxytocin from the posterior pituitary gland stimulates uterine contractions during labor, with the desired outcome of the delivery of the baby.

During cellular stress, positive feedback may promote cellular death to minimize oxygen and nutrition demands on the body, such as occurs with weight loss during times of scarcity. More commonly used throughout the body, however, is negative feedback.

Negative Feedback

The feedback loop of communication of hormones and chemicals in the body to decrease a desired output is called **negative feedback**. An example is when the body tries to reach a balance by releasing insulin when the glucose level in the blood is high. When blood glucose levels drop with the help of insulin secretion from the pancreas, then the signaling changes to stop releasing insulin so glucose levels do not fall too much. When glucose levels drop during fasting or sleep, the negative feedback loop then sends chemical messengers to the liver to break down glycogen, which is stored glucose, where it can then elevate blood sugar levels to the normal range. It is a constant balance and exchange of signals all with the goal of maintaining a stable internal environment.

Remarkably, the negative and positive feedback loops occur automatically. When body temperature rises, the negative feedback system in chemoreceptor sites of the thyroid and brain sense a higher-than-desired temperature, which triggers the action of sweating in the skin. Each body system works together to achieve balance in an ever-changing milieu.

Cellular Adaptation and Response

One powerful adaptation at the cellular level includes the inflammatory response, which is triggered by a stressor, pathogen, or antigen from inside or outside of the body. When a stressor is identified by chemicals and T cells in the blood, additional chemicals, called cytokines (e.g., histamine), are released to notify the surrounding area that an antigen is present. Mast cells release chemicals, which stimulate vasodilation and increase movement of white blood cells to the area. It is as if the immune system is alerting the body's military troops about an invasion and, through this chemical communication, vasodilation allows more troops to enter the battlefield. This cellular adaptation is a remarkable and quite sophisticated way to respond to threats.

Generally, inflammation is a helpful response to allergens and pathogens, but it can cause problems when the body attacks itself in a process called autoimmune hypersensitivity. Hypersensitivity is when the body's response is overreacting and causes additional and unwanted problems for the body such as autoimmune diseases like type 1 diabetes, lupus, multiple sclerosis, Hashimoto's thyroiditis, and others.

Types of Inflammation

Inflammation is a large factor that is both a stressor and response to stress. It can be either acute or chronic. An acute response is appropriate against a pathogen or antigen but can become detrimental when it continues for days, weeks, and even years. Acute inflammation will occur when there is a break in the skin, or even during hay fever season, but when it is chronic, it can become a devastating stressor to the body when nutrients and energy become depleted. People with chronic allergies experience lasting symptoms of physical stress, such as constant itching eyes, runny nose, skin inflammation, and emotional stress. Medications such as antihistamines can stop the inflammatory response and clinical symptoms.

LINK TO LEARNING

View this video to learn about the inflammatory response (https://openstax.org/r/77inflammatory) from Alila Medical Media.

A topic of popular interest is irritable gut syndrome, also known as leaky gut. The hypothesis is that certain foods and environmental triggers weaken the immune system, which is largely housed in the gastrointestinal tract. Bloating, fungal growth, brain fog, fatigue, and lethargy result when the gut is unable to fight these allergens. People who experience celiac disease or have a gluten allergy are familiar with the gastrointestinal bloating and distress from eating a food they are allergic to. The body identifies the food as an antigen, which results in uncomfortable inflammation of the gut.

The term **chronic inflammatory response syndrome (CIRS)** refers to conditions of chronic stress caused by chronic inflammation in the body. Other chronic conditions are now also being linked to an inflammatory response gone awry, such as in Alzheimer's disease or dementia due to inflammation in the brain (Kinney et. al., 2018).

Systemic Response to Inflammation

Inflammation is often local, due to a physical injury to the body's protective skin, but it can also be systemic when the body attempts to protect itself inside. When the inflammatory response becomes systemic, the body can experience great stress as it struggles to restore stability. Systemic inflammation can occur with generalized infections in the blood or with trauma. Conditions that cause any type of shock, such as anaphylactic, neurogenic, sepsis, or cardiogenic shock, can result in massive circulatory vasodilation and cause hypotension that threatens adequate perfusion to tissues.

Massive vasodilation, hypotension, tachycardia, and tachypnea, in response to infection and autoimmune disorders or burns, is referred to as **systemic inflammatory response syndrome (SIRS)**. It can be fatal if the body cannot overcome the extreme inflammatory response. What begins as the body's attempt to protect itself becomes systemic and affects all body systems, which may not be able to accommodate the widespread reaction.

LINK TO LEARNING

This video discusses SIRS criteria (https://openstax.org/r/77sirscriteria) and presents an example case for analysis.

Chemical Mediators

The **inflammatory response** is a complex process that involves many chemicals. The chemicals work in a cascading manner. Mediators of inflammation include leukotrienes, prostaglandins, vasoactive peptides known as kinins, phospholipids to activate clotting, and cytokines. Each chemical sends signals of stress in the development of the inflammatory response. The inflammatory response may be triggered by bacteria, pathogens, trauma, toxins, heat, or other noxious events. Histamine, bradykinin, and prostaglandins cause vasodilation, which allows fluids to flood the bloodstream, which cause swelling. The classic signs of inflammation are rubor (redness), pallor (blanching caused by swelling tissue), dolor (pain caused by inflamed tissue pressing against nerves), tumor (swelling), and calor (heat). Loss of function can also result when tissues swell, making mobility of the affected area unstable or painful, such as a swollen ankle after injury.

Pharmacological interventions target one or more of the signs of inflammation. Anti-inflammatories decrease swelling and block prostaglandins. Fever reducers act to decrease the fever within the tissues. Pain medications act to numb the pain receptors at the tissue site and block activation of nociceptors, which detect noxious stimuli. The inflammatory mediators of pain include prostaglandins, pro-inflammatory cytokines, and chemokines, which nonsteroidal inflammatory drugs and even some narcotics act upon.

Cellular Injury

The cascade of activating chemicals protects the body against further injury; however, depending on the severity of the stressor, this activity may exhaust the cell's ability to respond to and repair injury. As seen in the General Adaptation Syndrome, cells respond first in the acute stage with alarm and the inflammatory response, but if cells cannot overcome the insult to the body, efforts to adapt may lead to exhaustion. Large injuries seen in trauma and burns that destroy high volumes of cellular tissues may cause permanent damage.

Laboratory tests are used to help monitor the body's ability to respond, adapt, and overcome a physical stressor. Common laboratory tests for this purpose include measuring levels of lactate, blood urea nitrogen (BUN), and creatinine; a hemogram, which looks at red cells, white cells, and platelets; and end products of metabolism found in the urine, such as protein. When the body's muscles break down due to a stressor in a trauma or even a rigorous athletic event, high levels of proteins such as creatine kinase or creatine phosphokinase in both the blood and urine can reveal **rhabdomyolysis**, or massive destruction of muscle and the resultant increase in byproducts of muscle breakdown in the blood.

Managing inflammation is one process nurses can help with by administering medications as ordered and promoting a decrease in tissue swelling by applying cold compresses and elevating the inflamed area, if possible. Decreasing

cellular injury after a physical stressor can be managed with the actions abbreviated in the word PRICE: pain reduction, rest, ice, compression, and elevation. Additionally, nurses promote the patient's nutrition to support the energy of cells toward recovery.

Nutritional Imbalance

All the efforts to respond to a physical stressor, including the inflammatory response, require energy from the cells. Supporting the cells with adequate oxygenation and nutrition can increase the cells' ability to function and recover. Cells that are well hydrated and nourished have a better chance of being able to adapt to stress. Cells that are deprived of needed oxygen, fluids, and nutrition will not adapt well and may fail.

The core nutritional fuels for the body are carbohydrates, fats, and proteins. All are needed for cellular growth and recovery. Cells prefer carbohydrates as a fast-acting fuel to burn for adenosine triphosphate production but can use fats and proteins in the absence of carbohydrates or insulin, which allows glucose, as the simplest form of carbohydrate, to enter the cell. When the body uses fats or proteins as alternate energy sources, a negative byproduct is ketone bodies, which create an acidic environment for the cells. A balance of the macronutrients (carbohydrates, fats, and proteins) and micronutrients (vitamins and minerals) is needed for ideal cellular function. Hydration without added artificial flavorings, chemicals, excess calories, or caffeine is what cells need to function.

When cells have an imbalance of nutrients, cells die. Starvation at the cellular level is not conducive to good function or recovery from stress. Without adequate nutrients, red blood cells, white blood cells, chemical mediators, and platelets cannot be made, all of which are part of the inflammatory process. Without the inflammatory process, which includes the immune system's response, the body cannot adequately protect itself.

Hypoxia

A major purpose of the inflammatory process is to deliver oxygen to the site of injury or invasion. Vasodilation enlarges the area where red blood cells can flood the tissue area, delivering needed oxygen. All cells need oxygen to complete their internal metabolic processes, including the production of proteins, enzymes, and chemicals. Some cells may function through anaerobic processes, yet oxygen is needed for ideal functioning in the majority of the body's cells. The inflammatory process assists the body with the delivery of oxygen.

Physical Influences

There are many physical factors that influence the inflammatory response. These can include disruptions in the ability of the blood vessels to dilate or insufficient oxygen-carrying capacity of the red blood cells. If the body cannot deliver oxygen due to a blockage (ischemia); decrease in blood pressure, which pushes oxygen across cellular membranes (seen in shock or sepsis); or inadequate red blood cell count, seen in anemia or hemorrhage, cells will die.

An example of a physical influence that can affect the normal, well-intended inflammatory response is an injury to the brain, where normal swelling can cause increased cranial pressure. As the brain tissue swells, it has nowhere to expand in the hard, skull-encased area, and the swelling tissue pushes back on itself, possibly causing the brain to herniate through the spinal cord, which can cause death of the brain. Another example is when a bone is fractured with no break in the skin and then put in a closed cast before swelling has subsided. Again, because the inflammation has nowhere to expand, the tissue pushes back on itself, causing damage within, known as compartment syndrome. The medical remedy for these two examples is to surgically open the area to allow for tissue expansion. Casts are generally not placed until swelling has gone down; an open split is placed initially instead.

Temperature

The word inflammation is derived from the Latin word *inflammare*, which means to burn, and indicates the identification, even in ancient time, of a key feature of the inflammatory response to injury or infection. The body strives to keep the body in an ideal temperature range throughout the organs; this process is called thermoregulation. Using negative feedback, the body has a desired set point and senses variations in that temperature by chemoreceptors. If the body temperature elevates, sweating is elicited to decrease the core temperature. If the body temperature decreases below the set point, then muscles contract to shiver and stimulate heat production. All these adjustments are done autonomically.

During the inflammatory process, local temperature increases due to the increase in circulation to the body region

affected. Elevating the temperature is also a chemical attack to create an unsuitable environment for the survival of pathogens. When the body experiences SIRS, the temperature of the entire body increases, which can be uncomfortable to the individual and, in a hospital setting, is managed by antipyretics. In other medical naturopathic traditions, such as Indian Ayurvedic medicine, American Indian medicine, and traditional Chinese medicine, the fever from inflammation or illness is actually promoted because its effects help destroy pathogens that may be causing the illness. In Western medicine, fever is usually addressed quickly to promote patient comfort and rest.

Radiation

Radiation is both a promoter of injury and remedy for many cancerous conditions. Radiation, which, ironically, is **carcinogenic**, or cancer causing, is also used as a treatment for cancer. The etiology of its use is found in the physiological effects of radiation at the cellular level. Radiation can cause mutations in chromosomes during mitosis, damaging cells and their byproducts. It has the power to change the expression of genes, which is why it is used in cancer tumors. Radiation can be used to destroy undesirable tumor cells because it disrupts normal tumor cell growth. Fast-growing cells are most affected by radiation; unfortunately, that means noncancerous cells are also destroyed, such as hair cells and gastrointestinal lining cells, causing hair loss and nausea and vomiting, respectively.

Radiation-damaged tissues result in inflammation similar to the response seen after an attack by a pathogen, which is why oncologists limit radiation exposure (Schaue et al., 2015). The damaged tissue recovers with time as the body's regulatory mechanisms respond to remodel the skin and tissue for normal wound healing. Although radiation treatment has the goal to narrowly target the desired cancerous tissue area, the wide response of inflammation expands beyond the initial radiation border, and a wider range of tissue is negatively affected. A careful nursing assessment is needed to assess for peripheral tissue damage and intervene to promote comfort to aid the body's inflammatory response.

Trauma

Trauma, just like pathogens or radiation, will trigger the inflammatory response for protection. Any physical, emotional, or sexual trauma causes stress to the body. Traumatic injury produces excessive release of proinflammatory mediators, which activate vasodilation, white blood cell attraction to the area, and chemical release of histamine, cytokines, and prostaglandins.

In addition to stabilizing injured body appendages or bones and working toward hemodynamic and respiratory stabilization from a trauma, medical interventions address the increase in tissue swelling, fever, and pain. Generally, in a trauma with a fracture, the bones can only be stabilized initially with an open splint, rather than a closed cast, to allow for the inflammation to subside. Pain control, rest, elevation, and compression are common approaches to help decrease the inflammation in the acute phase. For massive systemic trauma, the inflammatory response also reacts systemically, leading to massive vasodilation, hemodynamic instability, and SIRS, often causing death.

Chemical Influence

In addition to the chemicals released during the inflammatory response, such as histamine and cytokines, the sympathetic nervous system prompts release of epinephrine and norepinephrine during stress, which further creates a demand on the cardiovascular and respiratory systems. The main chemical mediators during inflammation include (1) vasodilator stimulators such as histamine and serotonin, (2) peptides such as bradykinin, and (3) eicosanoids such as thromboxanes, leukotrienes, and prostaglandins (Abdulkhaleq et al., 2018). Additional chemicals released from the kidneys or electrolytes in the blood affect the inflammatory response and stress response.

Macrophages, neutrophils, and lymphocytes are drawn to the site of an injury within minutes as chemicals released from mast cells lining the site of injury are broken open and released due to the injury. Histamine, prostaglandins, leukotrienes, free radicals, serotonin, and even oxygen continue to promote a chain of organized responses that have cellular and vascular effects, which contribute to the inflammatory process. The inflammatory response also includes pyrogens (which initiate fever); interferons; plasma proteins, such as complement; and kinins that produce clotting as needed. After basic neutrophils and leukocytes are attracted to the area of injury, white blood cells further differentiate bringing helper T cells to the area to target antigens. It is as if the helper T cells are paint ball players that tag the offending pathogen with a marker protein so the white blood cells can recognize the enemy and engulf and destroy them through phagocytosis.

In modern medicine, counter-attacking chemicals are used in pharmaceuticals to decrease the innate chemical reactions of the body, such as antihistamines, antipyretics, and antibiotics. External chemicals, however, can be noxious to the body and trigger an inflammatory response. Air pollutants like car exhaust and smoke, and synthetic chemicals in beauty and cleaning products can be stressful to the body and trigger the body's allergic response. Sneezing, coughing, choking, wheezing, and runny eyes are results of the body's attempt to get rid of the irritant. Even chemicals in food products can stimulate an allergic reaction, which is seen in those with food allergies including gluten and food dyes.

Infection or Infectious Influence

A common cause of stress that triggers the inflammatory response is entry of pathogens into the body, including viruses, bacteria, and fungi. The body recognizes these protein-enveloped entities and cells as foreign, which then triggers the immune and inflammatory responses. Depending on the location and volume of pathogen, the body may be triggered to a localized or a systemic inflammatory response. If a pathogen enters the skin from a scratch or small wound, the inflammatory response is localized and easy to treat. Localized redness, heat from the site, swelling, and pain may result. If, however, a pathogen enters through the respiratory system, such as a flu virus, or gastrointestinal system, then a systemic reaction will follow because the larger body system affected.

Treatment for an infectious agent is focused on medications to treat the offending pathogen and commonly includes antibiotics, antivirals, or antifungals. Additionally, systemic medications are given, such as antipyretics for the comfort of the patient. Choosing the correct antimicrobial medication is, of course, key to success because the medication must be able to effectively kill the pathogen. Nurses will respond to orders that require a culture of the tissue, blood, secretion, or urine to identify the organism and its responsiveness to the right medication. Then, nurses will administer the prescribed antimicrobial at the correct times to maximize therapeutic response. With the decline in the pathogen population as a result of the correct pharmacological treatment, the inflammatory response also decreases, and the alarm stage of physical stress can end.

Immune Response

The immune system is a brilliant, complicated, and impressive system that is often not given adequate recognition because it is not as tangible as the other systems of the body taught in an anatomy class. The immune system can be divided into the innate and adaptive divisions. The innate division includes the first physical barriers to prevent infection or assault on the body such as the skin, mucus membranes, and higher acid levels in the stomach and vagina. The physical barriers are the first wall against pathogens and include larger mast cells that line tissues and organs, such as the endothelial lining in the stomach, respiratory tract, gastrointestinal tract, vagina, mouth, eyes, and nose. As discussed, if an injury occurs that breaks the cellular barrier, the mast cells are broken open, releasing histamine, which serves as a megaphone to call the immune system's attention to the area. Vasodilation and increased numbers of red blood cells, white blood cells, and platelets rush to the area.

The adaptive division of the immune system then takes over, using chemical mediators to mark the pathogens so immunoglobulins can identify the offending agents and destroy them. Memory T cells are formed to remember the unique protein structure of the pathogen to be ready for any future assault by creating an immunity to it. Young children who have not been exposed to common pathogens rely on the thymus gland in the center of the chest to create immunoglobulins, but after receiving vaccines and exposure experiences, their body becomes more mature and they can then rely on developed T cells and antibodies in the adaptive immune system.

Genetic Influence

The age-old question of nurture versus nature continues to be asked about development of diseases. Both genetic and environmental factors influence an individual's ability to respond to stress, injury, and infection effectively. It is true that some genetic factors result in a disadvantage in fighting stress and disease, such as in patients with congenital conditions like cerebral palsy and cystic fibrosis, but most individuals can strengthen or weaken their body's resilience and adaptation by their life choices.

One analogy is that your genetics may be like a loaded gun, but your behaviors of nutrition, sleep, hydration, exercise, avoidance of toxins, and overall healthy behaviors, or lack of them, are what aim the trigger toward or away from disease. Stress can activate or mutate cells at the chromosome level. Chronic stress causes strain, and as has been discussed in this module on inflammation, causes additional potential problems for and demands on the body. Genetic mutations occur when there is damage to DNA; as cells containing damaged DNA replicate, so do the errors, furthering the incorrect or damaged coding for the cells, tissues, and body organs. Although nurses may not be involved in genetic counseling, they are involved in patient education about healthy lifestyles, which has a powerful impact at the genetic level.

Cellular Healing

When cells are damaged, the body automatically moves quickly into recovery and repair through the inflammatory response. Oxygen and nutrients are brought to the damaged tissues and cells to help with restoration. Variations in healing time and ability, again, are affects by genetics; available resources, including nutritional support; and the mental health of the individual. General wound healing takes 14–21 days, but individual cells may heal more quickly with sufficient support.

Nurses can aid healing at the cellular level by providing the patient nutrition, hydration, adequate sleep, and mental health support. Nurses can help teach their patients to honor their body and make decisions that demonstrate respect for their body. Florence Nightingale, known as the mother of modern nursing, emphasized the importance of environmental cleanliness, air, water, and support to help a person heal from injury, infection, or disease. Even before germ theory emerged, she understood the relationship between an external supportive environment and the internal environment of the body to heal.

Cellular Regeneration

Cellular regeneration is the ability of the body to restore damaged or destroyed cells, tissues, and organs to full function. All cells within the body replicate and regenerate based on the type of cell they are and tissues they create. Nerve cells have a slower rate of regeneration; however; in recent studies, nerve cells have been seen to regenerate in areas where this has not been seen before. Patients with spinal cord injury or stroke have had amazing recoveries. Unfortunately, there are so many complicated variables that not all patients experience recovery success.

Beginning with the inflammatory response, cells can begin to regenerate after injury or antigen exposure as blood delivers oxygen and nutrition to damaged cells and tissue. The ability to regenerate depends on the existing health of the cell and organism. Documented methods that stimulate cellular regeneration include intermittent fasting; caloric restriction; reduction in triglyceride levels; decreasing sugar and alcohol consumption; stem cell supplementation; vitamin C, vitamin E, beta-carotenes, and lutein consumption; and supporting healthy inflammatory pathways. Foods high in healing nutrients include cruciferous vegetables like cauliflower, broccoli, kale, cabbage, bok choy, and brussels sprouts. Nurses can help monitor these factors and offer patient education on healing methods.

Cellular Replacement

Cellular replacement is the process of replacing an aging cell with a newer, identical cell. The human body experiences cell growth and destruction every day. Each time a cell divides, the cell duplicates its genetic material; however, the telomeres in each cell become a little shorter until they are depleted, and the cell eventually dies. When the cells die, another generation of cells is formed to replace the old one. Cell death can be accelerated or delayed by health and behavior choices. Accidents, illness, and injury can speed up cell death, and positive supportive behaviors and choices can extend telomere length and life.

Each specific cell type in the body has an established cellular replacement time frame. For example, skin cells in the outer epidermis are constantly being replaced by younger cells developed in the lower basal area. When a person repeatedly sunburns, those immature cells may not be ready to replace the older cells on the epidermis. The body rushes to repair the exfoliated surface cells, but in the hurry, the basal area may produce immature cells, which are prone to DNA mutations, leading to skin cancer. It is as if a person becomes in a rush to make paper copies and the copy machine is forced to speed up, making errors more frequently.

Cells are replaced throughout the entire human body every 7–10 years. White blood cells replace themselves within 2–5 days, red blood cells every 120 days, and skin every several days. Studies show that cells stop dividing after 50

or so divisions, leading to aging and eventual death.

The quest for youth and eternal life still is an unsolved mystery; in the meantime, nurses can help patients improve the length of their life by practicing healthy behaviors and learning to manage their own stress more effectively.

8.7 Role of Stress in Family Health

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the impact of stress in family health
- Discuss nursing implications in supporting family-centered care
- Identify means of social support for patients and family dynamics

Families matter. The term **family health** is the acknowledgement that the family as a unique entity also has a health status from healthy to diseased and troubled. Risk factors of stress affect people differently at different ages. Each person experiences common stressors unique to their age. Incorporating the individual patient as part of a whole unique family system can increase positive outcomes. The entire care team plays a role in acknowledging the patient's impact on their family during a hospitalization.

Impact of Family Health

Stress is generally discussed in terms of its impact upon an individual; however, the health and stress level of one family member will affect the family. The family itself is a unique entity and can also experience stress. For example, when a family moves from one house to another location, or a primary breadwinner loses a job, those stressors affect the health of the family as a unit. All families experience stress differently due to the makeup of the individuals and the stress management skills of the family members. Families who have been dysfunctional for generations may continue to see poor stress management skills unless the chain of behaviors can be broken. The same main categories that affect individual stress can affect the family as a whole and include demands, control, support, relationships, roles, and change. Common causes of family stress include

- birth of a child
- change in family housing.
- confusion in roles of family members
- death of a loved one
- divorce, marital problems, and separation
- financial burdens and insufficient funds
- overloaded schedules
- parenting and child discipline
- serious mental or physical illness of one family member
- work-life balance

Some of the most common reactions to stress that frequently are dramatized in Hollywood movies and can commonly be seen in a family unit include

- arguments fighting, and other poor communication
- dependence on and excessive use of food, alcohol, and other addictive substances
- fatigue and disconnection due to exhaustion
- financial difficulties
- inability to provide essential necessities of life for the family
- poor completion of roles and family duties
- withdrawal by family members

When a family unit is under stress, individual members suffer and can go on to develop other negative physical and emotional manifestations of stress. Nurses can acknowledge the impact a patient's stress may have on the family unit. Allowing and inviting family members to visiting hours and being a part of the healing process demonstrate advocacy for the family unit.

Promoting Family Health

Family health makes a difference in the effectiveness of how individuals deal with stress. Ideally, family members can go to each other for counsel and comfort. Including family members to patient education or therapy sessions can be positive. Encourage the family to work together to manage the stress. Provide resources to the family and support parents as they strive to be good role models for children on how to deal with stress effectively. Getting other family members involved in supporting a hospitalized family member can create unity.

When families are under stress, they often need a mediator and resources. A mediator is someone to listen, offer counsel, and point the family to resources. Nurses can be a mediator of sorts, but it is not the nurse's responsibility to be a professional marriage and family counselor. Nurses can be a patient and family advocate by providing a family resources and contact information for professional counselors and services in their community.

Communication

Each family has its own communication style; some are healthy, others are strained and troubled. Some families tease and joke playfully, others are sarcastic and hurtful to each other. Most families learn their communication style from the parents of each parent. Generational habits and skills are carried down and perpetuate.

Nurses can help families improve their communication by first assessing the effectiveness of communication through their interactions with family members. A hospital setting often brings together numerous family members who each interact with the patient and relay various information between the conversations. Hospitals have created policies and procedures to identify one key family member as the main contact person for the family. Having just one person to relay information to makes it easier on the hospital staff and prevents distortions of messages among various family members.

Family Education

Patient education is a large role of a nurse that can influence desired outcomes. Including family members in the room for patient education can help promote correctly understood information. Frequently, a nurse must give education to an ill patient who cannot recall the instructions well. Teaching a spouse or other close family member, and writing the information down increase the chance of correct messaging.

Enhance Social Support

Picture a bride and groom as the top centerpiece on a layered wedding cake that represents their marriage. When the couple is under stress, they can topple and fall off the cake; that is, the marriage is damaged. Now picture the concentric layers beneath the top layer that support the bride and groom at the top and make them more stable. A family unit is like that and it needs support, especially during times of stress. Each unique family is part of a larger community that contains resources and support. Unfortunately, in bigger urban areas, many families do not know about all the resources available in their city. Case managers and social workers are valuable team members the nurse can connect with to learn about resources for a patient and family.

Nurses can enhance social support of families by evaluating what services are needed through patient interviewing and communicating with family members. Then, a nurse can show initiative by communicating with the care manager or social worker on their unit or work setting. Language services, financial aid, employment, and medical supply companies are examples of some of the services available. Nursing students also experience stress and need emotional and social support (Labrague et al. 2017).

Nursing Implications

The implications for nurses in helping to strengthen home and family are powerful. What could be disastrous to a family during a family member's hospitalization can become a strength when support by the medical staff and nurses is given. Nurses are the gatekeepers of birth and death and in an important position to provide resources to families at critical points in their life.

How a nurse handles a new birth or the passing of a loved one makes a huge impact on individuals and families. Combining the art and science of nursing is a skill and makes a difference to lives. Providing care in a humane way can help decrease a normally stressful event. Even the birth of a baby is stressful, and a compassionate nurse can assess the needs of the family and make sure not just the physical needs of the baby are met but those of the entire

family. Simple gestures like offering a cup of coffee or juice to a waiting father or family members in a waiting room demonstrate compassion and awareness of others.

Family-Centered Care

Recognizing that the health of the individual affects the health of the family means expanding patient-centered care to the whole family. Inquiring about family members and their needs demonstrates concern and thoughtfulness. The tone of voice, gestures, eye contact, and culturally appropriate care to meet the needs of the family demonstrate family-centered care.

8.8 Pharmacotherapy and Complementary and Alternative Medicine

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe pharmacological treatment for stress
- Describe nonpharmacological treatments for stress
- Identify appropriate CAM therapies based on the patient's presentation
- Explain the nurse's role in educating patients on pharmacotherapy and CAM

As established, stress is part of life, but how one responds to stress depends on many factors and individual variables. What makes stress become distress also varies among individuals, their interpretations of stress, and their ability to cope with the stressor and resources available. Pharmacological and nonpharmacological resources are available to help. Nurses must be able to recognize the signs and symptoms of stress and be ready to help. When a nurse recognizes that a patient is experiencing stress or anxiety, they should share that information with the prescriber so pharmacological options can be offered to help the patient. If medications are not available or appropriate, the nurse needs to know about and offer nonpharmacological options. Nurses must be aware of both approaches because there are limitations and different outcomes with each strategy.

Pharmacotherapy and Stress

There is no medication that can cure stress; however, there are medications available to help address the cause of stress, as well as medications to help promote relaxation, allowing for a mind and body reset. Many people need help getting through a stressful event or difficult time, and pharmacological options are available. They help decrease the brain's stimulation of the sympathetic nervous system, which can provide a respite from the barrage of activated stress hormones. Pharmacotherapy is the use of medications to treat a condition or disease. Prescription medications are those ordered by a prescriber, who can be a doctor, nurse practitioner, physician assistant, or dentist. A concern about prescription medication is the patient's compliance with taking the medication as ordered in the correct quantity and prescribed directions. Nonprescription drugs are those available at a store and can be purchased without a doctor's order. The concern about over-the-counter (OTC) drugs is if the medication will be taken correctly as outlined on the medication label. Any medication has the potential for side effects and adverse reactions and requires good patient education.

The classes of medications commonly given for stress include anxiolytics, hypnotics, antidepressants, sedatives, psychotherapeutics, muscle relaxants, antimigraine agents, and narcotic pain medications. The most common drugs given for chronic stress are selective serotonin reuptake inhibitors (SSRIs) and tricyclic antidepressants. The most common overall medications taken OTC for stress are for tension headaches and pain associated with stress.

An interesting new option many Americans have begun to use is medical marijuana. Although federally illegal to purchase and use, the Federal Drug Administration has approved several medications with marijuana components, such as Megace, which is used as an appetite stimulant, and other compounds used for certain types of seizures. Medical marijuana is still a very controversial issue and states have been left to regulate its use. Some states have approved medical marijuana with various mixtures of the active components of tetrahydrocannabinol (THC) and cannabidiol (CBD), and medical marijuana clinics have expanded exponentially across the nation. There is anecdotal evidence that medical marijuana helps treat stress and anxiety disorders.

Anxiety and Depression

A category of medications that can be used successfully for a short time during stress is anxiolytics. The term literally means to lyse (or breakdown) anxiety. They are used commonly in a hospital setting to help patients relax

before a procedure and can also be used for acute episodes of panic. Anxiolytics can be very effective and can administered orally or intravenously. This group of medications helps people relax and even calm down during an acute anxiety or panic attack. To strengthen the effectiveness of this class, the nurse can also provide guided imagery, deep breathing exercises, and anticipatory guidance to help a patient know what to expect, which also can decrease anxiety. The most common anxiolytics include alprazolam (Xanax), chlordiazepoxide (Librium), clonazepam (Klonopin), diazepam (Valium), and lorazepam (Ativan).

Antidepressants can be effective for elevating the baseline mood of a person so they can cope better. Patients need good education about each class of medication because they are not "magic pills" to take away their problems. It is common with many of these classes of medications that the therapeutic level is not reached until 4–6 weeks after the patient begins taking them; at that point, the patient may begin to feel relief and a change in their depressed mood. Making sure patients are aware of that caveat and providing them additional resources to manage stress are key. There are documented genetic variations in the effectiveness of medications within each category. A challenge is that without genetic testing, patients may be given one of the many types of SSRIs available without seeing any improvement until they switch to another medication, which, again, takes an additional 4–6 weeks to evaluate for effectiveness. The most common classes of antidepressants (Saffai, 2022) are SSRIs, serotonin-noradrenaline reuptake inhibitors, noradrenaline and specific serotonergic antidepressants, tricyclic antidepressants, serotonin antagonists and reuptake inhibitors, and monoamine oxidase inhibitors.

Selective serotonin reuptake inhibitors are the most commonly prescribed antidepressants. The top four SSRIs used to treat depression are citalopram (Celexa), escitalopram (Lexapro), fluoxetine (Prozac), and sertraline (Zoloft).

Nurses must be aware of the side effects possible with any class of medication and follow the rights of medication administration: right patient, right medication, right dose, right time, and right dose. With each medication administration, the nurse should also provide correct patient education regarding the medication and possible side effects the patient should alert the nurse about. For instance, a condition the nurse must be aware of when administering SSRIs is serotonin syndrome. This potentially life-threatening condition is caused by an excess of serotonin in the body, typically resulting from the use of certain medications. Symptoms can range from mild to severe and may include agitation, confusion, rapid heart rate, high blood pressure, dilated pupils, muscle rigidity, and tremors. Prompt recognition and management, including discontinuation of the medications and supportive care, are essential to prevent complications. It is important for a nurse to recognize serotonin syndrome because it can rapidly progress to a life-threatening condition if left untreated. Identifying the signs and symptoms early allows for prompt intervention and management to prevent complications such as seizures, coma, and even death

Post-Traumatic Stress Disorder

PTSD was first identified among U.S. veterans who experienced major mental health trauma during wartime. Experiencing any assault or violence has a huge negative impact on any individual. Flashbacks of the trauma can haunt a person and disrupt their ability to move forward in life. According to the Mayo Clinic and VA studies, symptoms include:

- always being on guard for danger
- being easily startled or frightened
- irritability, angry outbursts, or aggressive behavior
- overwhelming guilt or shame
- self-destructive behavior, such as drinking too much or driving too fast
- trouble concentrating
- trouble sleeping

Years later, the same symptoms of PTSD were recognized among rape victims and victims of other personal assault or violence. Pharmacological interventions and counseling have been the mainstay of therapy.

Medical Marijuana

A controversial option that has evolved over the past four decades is the use of marijuana to treat symptoms of stress, anxiety, and chronic pain. The debate continues as medical research studies demonstrate confusing results. Some studies have shown marijuana, which includes both the hallucinogenic ingredient THC and the CBD components, decreases pain, anxiety, and acute stress, whereas other studies have revealed negative complications or no positive results at all. What complicates the use of this product is that it is currently illegal at the federal level,

as is possession of it. Some states, however, have legalized medical marijuana if it is prescribed by a medical professional with prescribing rights (Pacula et al., 2017).

There are many anecdotal stories of the effectiveness of marijuana, which perpetuates its use and popularity among the public. It has become an option for those without medical insurance because it can be purchased even without a medical prescription. A variety of products are available, including flowers and buds of the marijuana plant, as well as capsules, topical patches and gels, edibles, creams, drops, solids, and liquids (Pacula et al., 2017).

Marijuana is available by prescription in the form of Megace and dronabinol, with proven effectiveness seen in preventing certain types of seizures or stimulating appetite in those with poor nutritional intake. There is inconclusive evidence for its use in many other conditions for which people are using it, including amyotrophic lateral sclerosis, bipolar disorder, other psychoses, dystonia, glaucoma, and Huntington's disease.

REAL RN STORIES

Nurse: B.G, NP
Setting: Marijuana Clinic
Location: Utah

I am a family nurse practitioner and now work in a marijuana clinic. At first, I was quite skeptical about the use of marijuana for medical conditions and stress, but over the years I have changed my opinion. I have seen so many people experience relief from pain, stress, and anxiety that didn't receive the relief from other medications or methods. I'm glad it's an available option now.

Federal and Local Marijuana Laws

Since the 1970s, states have pushed against the federal law to prohibit the production, farming, and use of marijuana. Various states have successfully decriminalized medical marijuana growing and distribution. As of February 2022, 37 US states, 3 territories, and the District of Columbia have legalized cannabis. The THC component is the hallucinogenic component, which has not been shown to have any healthful benefits; however, cannabinoid products that contain CBD have shown some benefit.

Nurses need to be well informed about this issue because medical marijuana use has increased and patients want education. When assessing a patient or doing a medication reconciliation, the use of marijuana needs to be addressed without judgment or shame toward the patient.

Overview of Complementary and Alternative Medicine

The term **complementary and alternative medicine (CAM)** refers to health practices that are used that are not within **allopathic** (traditional Western) practice. The term **alternative** means "other" and is used to describe health practices that are other methods not generally taught in Western medicine. Because of the increasing diversity of the US population and the common use of home remedies not prescribed by providers, nurses need to know about CAM. Another term is **integrative medicine**, which means the CAM is used in combination with, rather than instead of, a prescribed order. For example, a client who has hypertension may take his prescribed medication but also drink herbal tea and practice meditation to help decrease blood pressure.

With the increasing use of CAM therapies in the United States, the National Institute of Complementary and Integrative Health was formed to collect research and establish guidelines for its use (National Institute of Complementary and Integrative Health, 2023). A barrier to having ample research is the lack of entities, typically pharmaceutical companies, interested in paying for the research. Without the hope of a monetary profit, pharmaceutical companies do not generally complete expensive research on organic products such as herbs, which are commonly used in CAM therapies.

As shown in Figure 8.6, CAM therapies can be categorized as follows: energy therapies, biologically based practices, manipulative and body-based therapies, mind-body techniques, and whole medical systems.

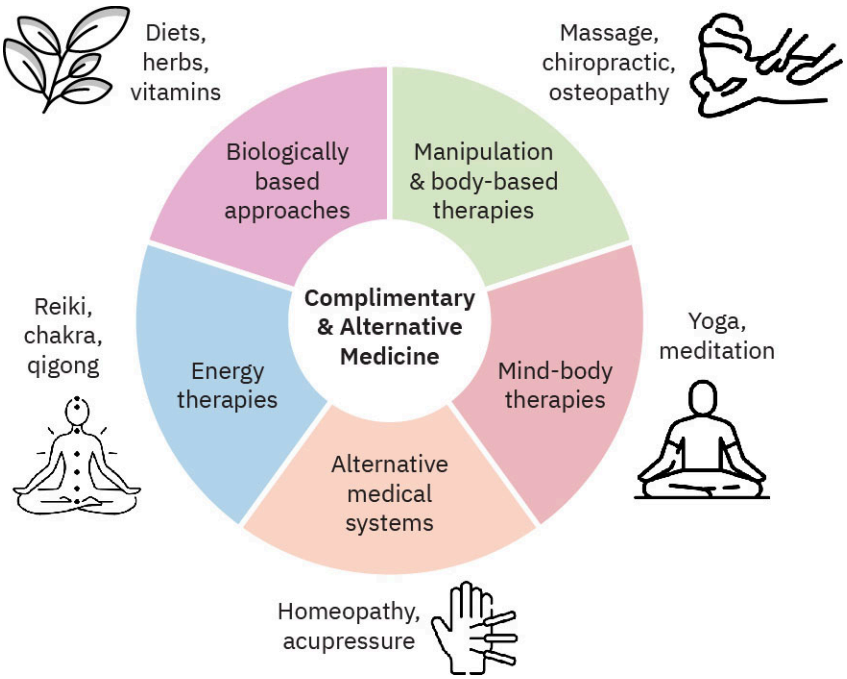

FIGURE 8.6 Complementary and alternative therapies are health practices outside of traditional allopathic medicine. (credit: creazilla.com, CC BY 4.0)

Energy Therapies

The core concept in many complementary and alternative therapies is the belief that energy in the body can be manipulated for healing. The foundation is that illness and disease are caused by a blockage in the body's natural energy flow. Each of the following therapies attempts to restore normal energy flow through different means:

- aromatherapy
- body manipulations
- biological based therapies
- energy therapy
- homeopathy
- herbal remedies
- naturopathy
- nutritional therapies
- whole systems

Energy therapies are the use of any therapy that affects the vital flow of energy through the body. First coined by Franz Mesmer in the 1800s, "mesmerized" was a term used to describe someone who was affected by a change in their energy flow. The concept of energy has been used by medical practitioners of many cultures, including traditional Chinese medicine (TCM), which identifies life energy as *chi*. In ayurvedic medicine, concentrated areas of energy are known as *chakras*. Manipulation of the body through massage and movement is also based on the belief of vital force energy.

More modern forms of energy therapy include red light therapy, which uses infrared or blue lights under which a patient can sit to stimulate circulation and redirect energy. Acupuncture used in TCM attempts to open blocked channels of energy. Reiki and qui gong also originated in TCM traditions and move energy throughout the body by self-movement or having a skilled practitioner move energy above body areas.

Many CAM therapies are based on the belief of vital source energy. Examples include the use of herbal medicine, acupuncture or acupressure, moxibustion, and cupping to help correct imbalances in the biofield of energy in the body to restore health. Without scientific proof, most people have experienced the stress relief that comes from a good massage.

Biologically Based Therapies

Biologically based therapies use herbs, plants, and aromas to bring relief and restore health. Biologically based

therapies include modifying nutrition components, aromatherapy, homeopathy, and naturopathy.

Diets high in certain macro- or micronutrients have been used to decrease the stress response as seen in diets that eliminate known allergens such as gluten, dairy, and eggs. Other forms include consuming certain herbs and vitamins as supplements for the desired outcome.

Aromatherapy in the form of scented candles has been used casually in homes for generations but has now received approval for use in hospital and surgery centers to reduce anxiety and stress. Smell is associated with memories and emotions through the olfactory nerve and can have stimulating or relaxing properties.

Homeopathy was first identified when practitioners took extracts of an active ingredient and administered them in much smaller quantities to provide the desired effects. The concept is that the essence of an herb or plant can be as effective as the entire medicine. Naturopathy is a general category of an approach to health promotion and disease prevention. A naturopath practitioner may use many types of CAM therapy in healing, whereas homeopathy refers to a specific focus on healing with tinctures of plants and herbs.

Manipulative and Body-Based Therapies

A core belief of manipulative and body-based work is to align the body's vital source of energy. Many of the practices focus on realigning the body and organs for the better flow of energy. Massage and chiropractic adjustments are two commonly used therapies. More complex methods are the Feldenkrais method of body alignment.

Whole Medical Systems

Whole medical systems incorporate elements of all these categories and originate from traditional cultural practices for millennia. Such systems include Ayurvedic medicine, Mexican folk medicine, American Indian health practices, and TCM. Most ethnic cultures and peoples around the world have their own versions of folk medicine that have been passed down through family members for centuries.

Studies show that immigrants to the United States may be leery of Western medicine and still prefer to practice their own cultural medicine. Nurses need to be open-minded and ask in a nonjudgmental tone what home remedies patients may be using. Often, the practices can be used with Western medicine, but occasionally there are contraindications, such as the avoidance of ginseng, ginger, and garlic as anticoagulants before surgery. Whole medicine practices may also include prayer, rituals, chanting, and other activities that may be quite helpful to decrease acute stress. These practices may even be used a complement to modern medical practices in the hospital setting if they are not disruptive to the medical and nursing care and do not disturb others.

Mind-Body Therapies

Mind-body therapies focus on calming the mind, which, in turn, can help calm the body. Strategies include mindfulness, meditation, yoga, breathing techniques, and even CBT. Nurses can easily use these strategies and guided imagery with patients who are stressed and anxious in the hospital setting.

Stress Management Techniques

Nursing students would do well to practice these techniques before exams also! Although there is no way to eliminate stress from our lives, we can learn to successfully manage our stress. Lists of strategies can be helpful, but ultimately, they must be individualized to whatever works for the person. The following are some strategies to help decrease stress:

- Avoid drugs and alcohol.
- Eliminate high-sugar and processed foods.
- Enjoy something that is energizing to you.
- Engage with faith-based activities and people.
- Engage in exercise.
- Get a massage.
- Provide self-care with rest and nutrition.
- Schedule time to relax.
- Spend time in healing nature.
- Talk to others.
- Take breaks from watching, reading, or listening to news stories, including social media.

- Do yoga and stretch.

Cognitive Techniques

Because there is such a direct correlation between the mind and body during the stress response, there are many activities that can used to help calm the mind and body. Challenging one's negative thoughts is the beginning of CBT. Thoughts create emotions, which affect behavior. If the thoughts can become controlled, they can help eliminate the anxiety producing physical manifestations of stress. Often asking "what is the worst thing that could happen now" creates introspection and connection with reality that the worst-case scenario is not even realistic. Using cognitive strategies can help decrease stress by controlling the downward spiral of negative and unrealistic thinking.

Physical Techniques

There are many strategies available to use the body to decrease stress. Learning biofeedback through breathing techniques can help decrease blood pressure and heart rate. Using cold compresses to the head, face, and neck can create vasoconstriction and reverse the dilation that occurs during the normal acute inflammatory response or catecholamine response of stress. Because there is such a direct correlation between the mind and body during the stress response, there are many activities that can used to help calm the mind and body. There is a direct correlation between stress in the body and stress in the mind. By learning to relax the body, the mind will follow, and vice versa.

Environmental Techniques

Environmental stimuli can either relax the mind or stimulate it toward stress. Using a calming environment can bring peace to the mind and body. Research has shown that nature is a potent stress reducer and can decrease blood pressure, respirations, and pulse. In our urban settings, people often become disconnected from their physical environment. People may become so accustomed to the noise of traffic and horns and people that they cannot hear the peaceful sounds of birds anymore. A simple action nurses can do is to turn off the noise of a television in a patient's room and allow them to sleep. Many hospitals have a television system in the room that can play nature sounds, which are much more healing than the news. Be aware of the physical environment that may be adding to the stress of a patient and try to exchange it for a peaceful ambience.

Nursing Management

The tasks of nursing management make for busy days and, at times, can be overwhelming. It is human nature to experience stress, but nurses must be cognizant of how their emotional state can influence others. For example, your demeanor as you step into a patient's room can set the tone for the interaction you are about to have. If you are in a hurry and impatient to complete your tasks, the patient will feel that energy and may make them feel as though they are the cause of your stress. It is important to plan your day and go about your work in a well-organized and purposeful way that decreases your stress and helps prevent any stress from being transferred to coworkers and patients.

Promote a Healthy Lifestyle

Nurses are in a unique position to teach healthy lifestyle behaviors to patients. Patients will "hear" your message in your own persona. If you come into a patient's room smelling of smoke or looking disorganized and complaining about not getting a meal break, they will sense your message of healthy living may be hypocrisy. As the saying goes, "the best sermon is your life." Learning about stress in this chapter may be a good opportunity for an assessment of your own stress and management strategies. What is working for you and what is not? Are there lifestyle behaviors you need to make that could decrease your stress? When will you begin? Nursing school is an ideal time to practice stress reduction strategies!

Coping Strategies as Interventions

Interventional strategies to help people cope vary based on what works for them. As a nurse, you can offer patients a list of strategies and help them identify several they are willing to try. Nurses can help the patient identify positive and negative types of coping strategies by asking, "How is that working for you?" If the outcome is negative, the nurse can help strategize about additional methods that could be used.

In a study done with nursing students, origins of stress revealed identified as exams, limited time for family and friends, negative interactions with clinical staff or faculty, work demands, and school-related finances. The study revealed that good coping strategies that helped nursing students included open communication, thinking through

desired outcomes, staying organized, and finding meaning and purpose in the stress (Labrague et al., 2017). Although nursing school is stressful, the desired outcome is graduating as a registered nurse, which is worth it!

Summary

8.1 Homeostasis, Stress, and Adaptation

- Homeostasis is a state of balance in the body. Through continual, often-automatic interactions among body systems, the body attempts to maintain homeostasis as environmental conditions change. Illness and death occur when homeostasis cannot be maintained.
- Stress refers to any disruption to the body's usual state. Stress is a universal part of life, yet individuals may respond differently to the same stressor for a variety of reasons, including physical, emotional, and psychosocial factors.
- Adaptation to stress is needed to maintain homeostasis. Positive adaptive behaviors can restore health, whereas maladaptive behaviors can further increase stress and produce negative outcomes.

8.2 Causes and Types of Stress

- Stressors can be perceived by the body as physical threats to its homeostasis.
- Stressors can be psychosocial, relating to the person's lifestyle, work, relationships, and emotional well-being.
- Stressors can be internal or external in relation to the body.
- Stressors can be short term (acute) or long term (chronic) based on the time frame during which the person experiences the stressor.
- Nurses need to evaluate stressors with the patient to help eliminate and address them.

8.3 Stress and Disease

- Stress can be both the event that activates a stress response and the physical response to a stressor.
- Examples of physical responses to a stressor include infection, trauma, allergic response, and activation of the sympathetic nervous system.
- The interplay of sociocultural, environmental, and mental factors in affecting a person's response to stress is called the Transactional Stress Model.
- Stress can be the cause of disease if not controlled and managed correctly.

8.4 Physiological Response

- The brain's physiological adaptation and response to stress occur through the nervous system.
- Within the autonomic nervous system are two divisions: the sympathetic and parasympathetic nervous systems
- The sympathetic nervous system responds autonomically by activating the body to fight or flee.
- The body attempts to adapt to the demands of stress by each body system.
- The role of the nurse is to identify indicators of physical and emotional stress in a patient.
- Nurses can use vital signs and physical examination findings to evaluate stress in a patient to deliver appropriate care

8.5 Psychological Response

- A stressful event can be neutral, positive, or negative, based on a variety of factors.
- Coping strategies need to be taught across the lifespan.
- The physical, emotional, cognitive, and behavioral effects of stress affect one's health.
- Physical effects of stress can be identified by a nurse during a physical examination.
- Identifying emotional and cognitive effects of stress requires additional interviewing skills by nurses.
- Behavioral effects of stress depend on a person's values, beliefs, age, abilities, thoughts, emotions, and resources.

8.6 Inflammation: Cellular Response to Stress

- Cells function on a continuum of a healthy state contingent on multiple factors that affect cell health.
- The body uses both positive and negative feedback to communicate within all the body systems to produce desired outcomes.
- The inflammatory response is an innate process of protection and attempts to promote recovery from pathogens, injury, or trauma.

- Causes of cellular injury include environmental and genetic factors.
- Cells can be injured as a result of extremes in temperature, poor nutrition, radiation, infections, trauma, and inability to regenerate and repair.

8.7 Role of Stress in Family Health

- Stress affects both the individual and the family unit.
- Family-centered care involves many nursing actions that demonstrate awareness, thoughtfulness, and support.
- Nurses can offer social support for patients and family dynamics.

8.8 Pharmacotherapy and Complementary and Alternative Medicine

- Pharmacological treatment is an option to dealing with stress.
- Nonpharmacological treatments are available options to help people deal with stress.
- Complementary and alternative therapies are viable solutions without negative side effects to help people manage and decrease stress.
- It is in the scope of the nurse to provide patient education about pharmacological and nonpharmacological strategies to address stress.

Key Terms

acute stress short-term bodily disruptions whose signs and symptoms last minutes, hours, or days
acute stressor short-term experience that generally appears suddenly and may cause severe distress, but whose signs and symptoms may last only several minutes, hours, or days
adaptation process of adjusting to the environment as conditions change, either suddenly or over time
adaptive behavior behavior that enables one to decrease distress; may be either positive or negative
allopathic referring to modern Western medicine
alternative referring to health practices that are other methods not generally taught in Western medicine
antigen something that generates an antibody response—hence the term “anti-gen”
apoptosis normal cell death as controlled part of cellular growth and development
autonomic dysreflexia condition seen in patients with spinal cord injury in which the body tries to rid itself of a stressor that the brain cannot recognize
autonomic nervous system division of the peripheral nervous system that responds automatically to chemicals and hormones in the body through sensory and motor neurons
autophagy death of a cell by self-destruction
carcinogenic cancer causing
chronic inflammatory response syndrome (CIRS) conditions of chronic stress caused by chronic inflammation in the body
chronic stress long-term bodily disruptions whose signs and symptoms last weeks, months, or years
chronic stressor long-term experience; it produces stress signs and symptoms that may last weeks, months, or years
complementary and alternative medicine category of nontraditional medicine that explores other modalities to treat the body for healing and wellness
coping ability to adapt and manage a stressful event
cortisol natural hormone emitted from the adrenal cortex, known as the stress hormone, and related to increases in blood glucose and response to the sympathetic nervous system
family health impact of health and illness upon the entire family that may be experienced by one individual in the family
General Adaptation Syndrome theory by Dr. Hans Seyle of the physical stages the body experiences resulting from stress, including alarm, resistance, and exhaustion
homeostasis state of balance in the body
hypothalamic-pituitary axis (HPA) messages from hormones in the blood (the endocrine component) and the nervous system (the neurological component) pass through the hypothalamus and pituitary gland in the brain
inflammatory response initial response of the body to fight against pathogens or insults to the body, beginning with vasodilation to increase oxygen, blood, and antibodies to the area of injury

integrative medicine modalities and practices that are used with modern medicine
local adaptation syndrome localized version of the inflammatory response to stress
maladaptive behavior negative behavior performed to decrease distress
maladaptive coping use of strategies to decrease stress that result in other negative outcomes
negative feedback process of communication within the body to decrease an outcome of the body
negative stress stressful event that produces unhealthful outcomes for the body, such as illness or disease; also causes distress
parasympathetic nervous system one of the two divisions of the autonomic nervous system (aka, the "feed and breed" response); this system prepares the body to rest and digest
physical stress involves measurable disruption to the body
positive feedback communication process within the body to increase a desired outcome in the body
positive stress stressful event that produces healthful outcomes for the body, such as stronger muscles or improved cardiovascular function
psychosocial stress mental and emotional response to stress
rhabdomyolysis massive destruction of muscle and resultant increase in byproducts of breakdown in the blood
stress disruption to the body's usual state
Stress Adaptation Model model of health developed by Hans Seyle in which stress and health are biochemically linked
Stress Transactional Model theory that stress is a transaction and cascade of events that occur in the body in response to a stressor
stressor event or stimulus that activates an individual's stress response
sympathetic nervous system part of the nervous system that controls many of the body's automatic functions, such as heart rate, blood pressure, and perspiration
systemic inflammatory response syndrome (SIRS) serious systemic condition characterized by massive vasodilation, hypotension, tachycardia, and tachypnea, in response to infection and autoimmune disorders or burns.
telomeres distinctive structures at the end of a strand of a chromosome within the cell

Assessments

Review Questions

1. What statement is true regarding homeostasis?
   a. Homeostasis is the body's natural state of balance.
   b. Each body system works independently to maintain homeostasis.
   c. Homeostasis cannot be restored once illness has occurred.
   d. Emotional issues do not impact the homeostasis of the body.

2. The nurse is caring for a client who is admitted with multiple broken ribs sustained in a motor vehicle accident. What is the correct clinical judgement of the nurse for this client?
   a. The client will experience both mental and physical stress.
   b. The client will only experience physical stress.
   c. The patient will not have difficulties healing from the physical stress.
   d. Psychological stress will not be involved for this patient.

3. What is maladaptive behavior?
   a. a balance of body systems
   b. a negative response to stressful event
   c. an event perceived as negative
   d. a model explaining how the body responds to stress

4. What is a true statement about stressors?
   a. All stressors are external.
   b. All stressors are internal.

c. All stressors are interpreted differently based on culture, values, and beliefs.
d. Stressors that are managed quickly are chronic.

5. What is an example of an internal stressor a person may experience is?
a. a viral infection
b. loss of a job
c. emotional turmoil over low self-esteem
d. car accident

6. What is an example that demonstrates an individual experiencing a moderate stressor?
a. a student preparing for final examinations
b. a family experiencing loss of housing from a natural disaster
c. a nurse working in a busy emergency department
d. an individual preparing to move into a new home

7. The nurse is caring for a client who has recently suffered a mental breakdown after her spouse of 55 years died. She smiles and laughs with hospital personnel who come into her room for various activities. What is the best assessment by the nurse?
a. The client clearly has gotten over her emotional stress.
b. Stress is experienced differently by individuals who may manifest their adaptive behaviors differently.
c. The client needs a psychiatric evaluation because her behavior is not appropriate for her grieving and stressful event.
d. No action is needed by the nurse.

8. What is an example of a statement by the student nurse that demonstrates understanding of the Stress Transaction Model?
a. All individuals experience stress the same way.
b. If an individual's stress reaches the exhaustion phase, the client may die.
c. Nurses cannot change the progression of stress for an individual.
d. Nurses can only use medications to intervene in a stressful event.

9. What disease processes can be significantly influenced by stress as a stimulus?
a. musculoskeletal disorders
b. respiratory infections
c. type 2 diabetes
d. renal failure

10. The nurse is preparing a patient for a coronary bypass heart graft surgery. Before handing off the patient to the transport team, the nurse obtains the patient's vital signs and notes an elevated blood pressure and heart rate. What stage of the General Adaptation Syndrome should the nurse suspect the patient is experiencing?
a. exhaustion stage
b. alarm stage
c. resistance stage
d. cardiac decompensation stage

11. The nurse is caring for a client who has been under extreme stress at home and work and comes to the hospital after experiencing a myocardial infarction (heart attack). Upon physical examination, what would the nurse expect to see?
a. relaxed physical appearance
b. regular and stable vital signs
c. disrupted thought processes and anxiety
d. clear communication from the patient

12. What physical manifestations are seen when the sympathetic nervous system is activated during stress?
   a. dilated pupils, constipation, tachypnea, tachycardia
   b. constricted pupils, diarrhea, bradycardia, bradypnea
   c. dilated pupils, warm skin, regular heart rate, hypertension
   d. constricted pupils, increased gastric juices, relaxed breathing

13. The nurse recognizes the patient is experiencing a positive psychological impact when has what sort of reaction?
   a. feeling anxious or depressed
   b. feeling energized and excited
   c. feeling confused and unclear
   d. having no emotions toward the event or stressor

14. The nurse is caring for a patient who is given a new diagnosis of cancer. During the physical assessment, the nurse notices a new bald spot on the patient's head, jagged fingernails, and alcohol on the breath. What is the nurse's best therapeutic response?
   a. "Cancer isn't always fatal. It'll be okay."
   b. "I notice you have been pulling out your hair. Do you think that will help?"
   c. "Do you want me to call your clergyman?"
   d. "I notice some changes in your appearance. Please tell me how you're feeling about your new diagnosis."

15. What statement best aligns with the definition of the appraisal of a stressful event?
   a. the physiological response to stressors in the health care setting
   b. the process of evaluating the significance and potential impact of a stressor on an individual's well-being
   c. the implementation of coping strategies to manage stress in the workplace
   d. the assessment of patient satisfaction with nursing care during stressful situations

16. The nurse is teaching a student nurse about the negative feedback response to stress to stabilize vital signs. What is an example of negative feedback?
   a. Blood pressure is elevated during an infection.
   b. The body works to reduce temperature from overexposure by sweating.
   c. The respiratory rate is increased during sleep.
   d. The level of consciousness is decreased due to head trauma.

17. The nurse is caring for a client who has an infection. What clinical manifestations will the nurse expect to see during the acute phase of the inflammatory response?
   a. cyanosis of the skin, bradycardia, and bradypnea
   b. tachycardia, elevated temperature, possible hypotension
   c. shortness of breath, tachycardia, and low red blood cell count
   d. fewer white blood cells, low lactate level, and high BUN and creatinine levels

18. What cause of cellular injury is most commonly found in clinical practice?
   a. inadequate blood supply
   b. nutrient-deficient diet
   c. regular exercise
   d. chemical exposure

19. How does stress typically affect family health?
   a. Stress has minimal impact on family health.
   b. Stress can lead to improved family communication.
   c. Stress can negatively affect family dynamics and overall well-being.

d. Stress only affects individuals, not families.

20. What is a crucial nursing implication in supporting family-centered care?
a. prioritizing the individual patient needs over family concerns
b. limiting family involvement in care decisions
c. recognizing and respecting the importance of family involvement in patient care
d. avoiding unnecessary communication with family members

21. A patient wants to use a nonpharmacological approach to treat stress. What could the nurse recommend?
a. nonsteroidal anti-inflammatory drugs
b. prescribed narcotics
c. an SSRI antidepressant
d. meditation and focused breathing

22. When administering a new SSRI antidepressant prescription to a patient, what is an important concept to teach the patient about this class of drug?
a. It must be taken with food and water.
b. It may cause nausea and diarrhea.
c. It may take 4 weeks to reach therapeutic level.
d. It cannot be taken with grapefruit juice.

23. The nurse is caring for a patient who is admitted for a head trauma and is not allowed to have narcotics for pain to avoid masking any signs of increasing intracranial pressure. What safe alternatives could the nurse offer to help decreasing pain and stress?
a. breathing techniques and guided imagery
b. morphine given at half dose
c. dilantin as prescribed
d. ventilator support by the respiratory therapist

Check Your Understanding Questions

1. Sarah, a 40-year-old mother of two, has recently been diagnosed with breast cancer. She is undergoing chemotherapy treatments while trying to balance her responsibilities at home and work. Her husband, John, is supportive but struggles to cope with the emotional strain of seeing his wife go through treatment. Their teenage children are also experiencing stress and anxiety about their mother's illness. Describe how stress may affect the health and dynamics of Sarah's family during her cancer treatment.

2. Sophia, a nurse in a community health clinic, is caring for Maria, a single mother of three who has recently been diagnosed with diabetes. Maria is overwhelmed by her diagnosis and struggles to afford her medication and make healthy lifestyle changes. She expresses concerns about managing her diabetes while taking care of her children and working full-time. Identify means of social support that Sophia can recommend to Maria and her family to help them cope with her diabetes diagnosis.

Reflection Questions

1. Identify some strategies you as the nurse can offer a patient who may be experiencing both physical and psychological stress from a hospitalization.

2. Imagine you are a nurse caring for a client who is about to receive their first dose of chemotherapy. The client has developed high blood pressure and tachycardia and is now hyperventilating. How might stress have caused these changes in vital signs?

3. You are a nurse working on a busy medical-surgical unit. One day, you admit Mrs. Johnson, a 65-year-old woman who has been diagnosed with cancer. Mrs. Johnson is accompanied by her husband, who appears visibly distressed and overwhelmed by his wife's diagnosis. Throughout Mrs. Johnson's hospitalization, you notice that Mr. Johnson seems withdrawn and hesitant to leave his wife's side, indicating that he may be

struggling with emotional support needs. Reflect on how you would approach identifying and addressing social support for both Mrs. Johnson and her husband during this challenging time.

What Should the Nurse Do?

Jane, a 35-year-old woman, comes to the emergency department complaining of chest pain and difficulty breathing. She reports feeling overwhelmed and anxious for the past few weeks due to increased workload at her job as a project manager. She mentions experiencing frequent headaches, insomnia, and irritability. Jane has a history of hypertension and migraines but is otherwise healthy. On assessment, her blood pressure is elevated at 160/90 mm Hg, heart rate is 110 beats per minute, respiratory rate is 24 breaths per minute, and oxygen saturation is 95% on room air. She appears restless and diaphoretic.

1. What psychological factors might be contributing to Jane's presentation, and how do they interact with her physical symptoms?
2. How can the nurse provide a supportive and calming environment for Jane to help alleviate her acute stress symptoms?

You are caring for a young adult who comes to the clinic for an appointment and physical exam for a sports requirement. The young adult did not have an appointment and is told she cannot be seen. Rather than viewing it as an inconvenience that she must schedule the appointment for another day, she begins to shout at the front desk and demand an appointment today. Her response seems exaggerated and irrational.

3. As the nurse, what initial steps should you take when faced with the young adult's exaggerated and irrational behavior at the front desk?
4. Why is it important for the nurse to conduct an assessment of the young adult's current perceived stress and threats?
5. What potential factors might contribute to the young adult's behavior in this scenario?

You are studying with a fellow nursing student who confides in you about being stressed due to school demands, limited income, and a new breakup with a boyfriend. She admits she cannot study and now has the added stress of doing poorly on the upcoming exam. She is tempted to cheat on the exam to pass.

6. How can you support your fellow nursing student in developing healthy coping mechanisms to manage her stress effectively?
7. What are some strategies you could suggest to help her address the school demands, financial challenges, and emotional distress caused by the breakup?
8. How can an understanding of the physiological and psychological effects of stress help you provide empathetic and effective support to your fellow nursing student during this challenging time?

Ms. Greene, a 45-year-old woman, presents to the emergency department complaining of severe abdominal pain and tenderness. She reports experiencing intermittent fever and chills over the past few days. Ms. Greene has a medical history of type 2 diabetes and hypertension. On examination, her vital signs reveal a temperature of 38.9°C (102°F), heart rate of 110 bpm, blood pressure of 150/90 mm Hg, and respiratory rate of 22 breaths per minute. Upon further assessment, localized inflammation and guarding are noted in the right lower quadrant of her abdomen. Based on her symptoms and medical history, differential diagnoses include appendicitis, diverticulitis, or pelvic inflammatory disease. Further investigations are warranted to identify the underlying cause of her symptoms and initiate appropriate treatment.

9. What clinical manifestations would prompt the nurse to suspect an inflammatory process in Ms. Greene's case?
10. What immediate nursing interventions would be appropriate to manage Ms. Greene's symptoms and stabilize her condition?

Competency-Based Assessments

1. How does understanding the fundamental concepts of stress aid nursing students in recognizing signs and symptoms of stress in patients?
2. Explain the relationship among stress, adaptation, and homeostasis in the context of a patient experiencing a chronic illness.
3. How might an individual's past experiences influence their response to stress in the present?

4. Provide examples of how chronic stress may contribute to the development or exacerbation of autoimmune disorders.
5. What clinical manifestations would a nurse recognize when a patient is experiencing acute stress?
6. Compare and contrast the sympathetic and autonomic nervous systems' responses to stress. How can this knowledge guide nursing interventions?
7. As a clinical nurse, when you encounter a patient exhibiting signs of stress, how can you use the theory of adaptation when providing care for this patient?

CHAPTER 9

Management of Chronic Illness

FIGURE 9.1 This wheelchair-bound patient uses a service animal but is still able to participate in daily activities, despite chronic illness. (credit: "Drive to support assistance dog owners in Dudley borough" by Dudley Council/Flickr, CC BY 2.0)

CHAPTER OUTLINE

INTRODUCTION You are a nurse assessing a 57-year-old female patient, Mia, with a history of a musculoskeletal trauma that has kept her in a wheelchair since she was 10 years old. She has also recently been diagnosed with a seizure disorder that requires the use of a service dog. She has been working closely with her care team to manage her symptoms and improve her quality of life as much as possible. She is looking forward to getting out of the house more and being around friends now that she has a trained service dog that can detect her seizures before they occur.

Regardless of their specialty and practice setting, nurses will inevitably encounter patients with chronic illness, such as Mia. Long-term but often manageable health problems affect large portions of the population despite factors such as age, gender, ethnicity, and geography. For this reason, it is important that all nurses become knowledgeable about chronic illness and are adequately prepared to care for patients with chronic medical conditions.

9.1 Chronic Disease and Illness (Prevalence and Etiology)

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define chronic disease
- Discuss the impact of chronic disease and illness on patients
- Discuss demographic factors that influence chronic disease and chronic illness

Chronic diseases and illnesses are disorders that have a slower onset and are long-lasting. In comparison, **acute disease** refers to an illness that develops quickly and lasts a relatively short time, typically days or weeks (National Council on Aging, 2024). Chronic disorders affect more than half of the US population and are the leading causes of death and disability in the United States (Centers for Disease Control and Prevention [CDC], 2022a). They cost the US health care system nearly $3.7 trillion annually, accounting for 90% of the nation's total health care costs (CDC, 2023b).

The significance of chronic diseases and illnesses on the health of the population, coupled with associated economic costs, has shifted the focus of health care and research to disease prevention and health promotion (Healthy People 2030, n.d.). This shift has prompted the US government and health institutions to prioritize population health and implementation of strategies to prevent and mitigate the effects of chronic illness and disease.

Chronic Disease

We define **chronic disease** is defined as a medical or health problem that lasts at least 1 year and requires ongoing medical attention or limits activities of daily living (ADLs) (CDC, 2022c). This definition encompasses the pathophysiological causes of the health problem and the disorder itself but does not address the subjective feelings and experiences of the patient who is living with the illness. Examples of chronic diseases include

- Alzheimer disease
- arthritis
- cancer
- cardiovascular disease (CVD)
- chronic kidney disease
- chronic lung disorders (e.g., asthma, chronic obstructive pulmonary disease [COPD])
- diabetes mellitus
- heart failure
- hyperlipidemia
- hypertension
- HIV
- mental health disorders (e.g., anxiety, depression)
- osteoporosis
- stroke

Chronic Illness

Many people use *chronic disease* and *chronic illness* interchangeably, but it is useful to distinguish between the terms. Although the definition of chronic disease refers to the disorder itself, **chronic illness** is defined as the human experience of living with a chronic disease (Martin, 2007). This definition encompasses the emotions, values, and beliefs of the individual experiencing the chronic condition and the impact the disorder has on their quality of life and ADLs.

The feelings and experiences associated with living with chronic illness vary significantly from person to person and can change frequently depending on factors such as age, the presence (or lack) of social support, and other social and demographic characteristics. As a nurse, it is important to understand that not all patients experiencing chronic illness will successfully cope with their condition in the same way. Nurses must be able to communicate effectively and implement treatment and support strategies that are reflective of the patient's beliefs and values as they relate to their chronic conditions.

Demographic Factors Affecting Chronic Disease and Illness

Age, gender, and culture are three demographic factors that can have a significant impact on chronic disease and illness. For example, a child or adolescent experiencing a chronic disease is likely to have a completely different outlook on life than an older adult, due to differences in their respective lived experiences. Another example is the increased prevalence of certain chronic diseases seen in one gender compared with the other. Specifically, osteoporosis, depression, and arthritis are all more commonly seen in females than in males (Temkin et al., 2023). Additionally, an individual's culture, including factors such as religion or spiritual beliefs, may influence how they approach and cope with chronic illness. Regardless of the factors in any given case, it is imperative that the nurse provide patient-centered care that considers the specific preferences and needs of the patient.

CULTURAL CONTEXT

Culture and Perspectives on Chronic Disease

Culture provides an important source of values and comfort for patients, families, and communities, and it often influences how they view chronic diseases. Some cultures may view chronic disease as a punishment or a test of faith. In others, chronic disease may be attributed to environmental factors. Cultural beliefs also often influence the types of treatments sought for chronic disease. Traditional healing practices, such as herbal medicine or spiritual rituals, may be preferred over Western medical interventions in some cultures. For example, Asian Americans are more likely to use complementary and alternative medicine compared to other races (Felicilda-Reynaldo et al., 2020). It is important for the nurse to remain open-minded and nonjudgmental about the patient's cultural beliefs and preferences with regard to chronic disease.

9.2 Comorbid Chronic Diseases

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define comorbidity and its financial impacts
- Explore common examples of comorbid chronic diseases
- Discuss unique health care needs and health care coverage for comorbid chronic diseases

If it is difficult to live with one chronic disease, imagine the challenges facing patients with multiple chronic diseases simultaneously. In fact, more than 25 percent of individuals with chronic illness are diagnosed with two or more chronic conditions (Boersma et al., 2020). This is significant considering that individuals with chronic illness report lower health-related quality of life and have higher health care costs and a substantially increased risk of morbidity and mortality.

Comorbidity

The simultaneous presence of two or more medical conditions is referred to as **comorbidity**. It has a profound impact on **disease burden**, the total effects of a disease on an individual or a society. This burden of disease, especially when it involves chronic conditions, affects many aspects of health care, including finances and health insurance coverage, both of which are discussed in more detail in the following sections.

Financial Impacts from Comorbid Chronic Diseases

As noted in the previous module, nearly 90% of health care costs in the United States are related to chronic illness (CDC, 2023b). This highlights the importance of chronic disease burden on both the economy and personal finances. As the number of diagnosed chronic conditions increases for an individual, so do the number of emergency room visits, patient readmissions, prescriptions, and outpatient clinic visits, as well as the length of inpatient hospital stays. These increases in required health care services result in higher out-of-pocket costs and health care spending by insurance companies and health care institutions. Americans diagnosed with five or more chronic conditions account for only 12% of the population but make up nearly half of total health care spending, again highlighting the significance of the relationship between chronic illness and increased health care expenditures (Buttorff et al., 2017). This places an extra financial burden on the patients themselves as well as on the health care system and the overall economy.

Health Care Coverage for Comorbid Chronic Diseases

Health insurance coverage is a topic that has been debated and discussed at length by politicians, legislators, and individual health care consumers. Although consensus about the best course of action for the provision of health insurance remains elusive, it is clear that health insurance coverage becomes more complex with the presence of chronic comorbidities.

Coverage for chronic conditions varies depending on the type of health insurance acquired. Two of the most common health insurance plans for patients with chronic disease are offered through federal programs such as Medicare and Medicaid, both of which are administered by the Centers for Medicare and Medicaid Services (CMS). However, these programs have specific eligibility requirements that may not allow all individuals with chronic illness to obtain coverage. Table 9.1 lists the eligibility requirements for each program and some of the services covered (CMS, 2023).

Characteristic	Medicare	Medicaid
Eligibility requirements	• Older than 65 years Or: • Presence of a disability or diagnosis of end-stage renal disease or amyotrophic lateral sclerosis (regardless of age)	• Individuals and families with low income (determined on the basis of household size and other factors)
Covered services	• Hospital services • Medical care (e.g., clinic visits, laboratory services, outpatient care) • Prescription medications • Some medical equipment	• Dental care • Hospital services • Long-term care • Medical care • Medical equipment • Prescription medications • Some vision benefits

TABLE 9.1 Comparison of Medicare and Medicaid

Examples of Comorbid Chronic Diseases

There are a multitude of common chronic diseases, several of which tend to occur as comorbid comorbidities. This is often due to certain characteristics of the disease, such as anatomic location or underlying pathophysiology, which can manifest as multiple disorders with similar etiologies. For example, one of the most common pairs of comorbidities is hypertension (i.e., elevated blood pressure in the blood vessels) and hyperlipidemia (i.e., elevated cholesterol in the blood vessels). This is likely because hyperlipidemia results in the deposition of fatty plaques in the vasculature, which increases the force of blood through the vessels, resulting in hypertension (Healthmatch, 2022). In this case, the presence of one chronic condition (hyperlipidemia) results in the development of another (hypertension). Other chronic conditions that often exist as comorbidities include:

- atherosclerosis and CVD
- cerebral vascular disease and carotid stenosis
- COPD and other upper respiratory disorders (e.g., chronic laryngitis, chronic sinusitis)
- diabetes mellitus and CVD
- mood disorders (e.g., depression, anxiety, bipolar disorder) and substance use disorders
- osteoarthritis and other autoimmune disorders

Comorbidity Management with Polypharmacy

With an increased prevalence in diagnosed comorbid chronic conditions, there is often an associated increase in the number of medications prescribed to treat each condition. The simultaneous use of multiple medications by a single patient is called **polypharmacy** (Figure 9.2). Polypharmacy can result in negative outcomes, including adverse medication reactions and overdoses, so it is important for nurses to be aware of the risks associated with polypharmacy when caring for patients with multiple comorbidities. Nurses should be prepared to advocate for clear

communication between providers and patients to mitigate these associated risks.

FIGURE 9.2 Polypharmacy is common in older adults, because many suffer from multiple chronic conditions. (credit: National Institute on Aging, public domain)

Read this article (https://openstax.org/r/77polypharm) to learn about efforts to reduce the effects of polypharmacy in older adults.

9.3 Chronic Illness and Disability

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define disability and identify common diseases that contribute to disability
- Discuss the chronic effects of disability on a patient's wellness continuum
- Examine the legal and ethical considerations of providing equitable care for an individual with a disability

Chronic disease has the potential to negatively affect all aspects of everyday life for those with such a diagnosis. This is especially true for those diagnosed with multiple chronic conditions. These conditions can result in physical disabilities and take emotional, mental, and financial tolls on a person's overall health and well-being. Fortunately, in the past several decades, legislation has been passed and financial resources have become more readily available for individuals with disabilities related to chronic illness. However, there is still much work to be done to ensure equitable and adequate treatment for individuals with disabilities, both within the health care system and in everyday life.

Disability

A **disability** is a limitation in function or performance of everyday activities. Disabilities often occur because of chronic illness. They vary from person to person but can include the inability to effectively see or hear, perform ADLs, work a job, or complete school assignments. One in four Americans lives with a disability that affects their everyday life (CDC, 2023c). The most common disabilities in the US include:

- cognition: difficulty concentrating, remembering, and making decisions
- hearing: complete deafness or severe hearing loss
- mobility: difficulty walking or climbing stairs
- self-care: difficulty performing ADLs
- vision: complete blindness or severe loss of eyesight

Individuals with disability are also at higher risk for having obesity, smoking, and developing additional chronic conditions, including heart disease and diabetes, all of which negatively affect overall health and well-being (CDC, 2020).

Effects of Disability on a Patient's Wellness Continuum

Though many people may assume wellness is simply the absence of illness, it is a multidimensional concept that includes several different components (Figure 9.3):

- emotional health
- meaningful spiritual life

- mental health
- physical health
- positive relationship with one's environment
- positive relationship with one's financial status
- positive relationship with one's occupation
- satisfying social life

FIGURE 9.3 Wellness is a multidimensional concept that encompasses several components. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

In addition to being multidimensional, wellness exists on a continuum: there exists a wide variety of individual definitions of health. Figure 9.4 illustrates the illness–wellness continuum. On one end of the continuum is premature death; the other end represents a high level of wellness. The middle portion of the continuum represents individuals who may have some aspects of wellness and some aspects of illness. Therefore, even with a chronic disease diagnosis, individuals may still fall somewhere on the high end of the continuum if they ensure they are improving other aspects of wellness beyond just physical health.

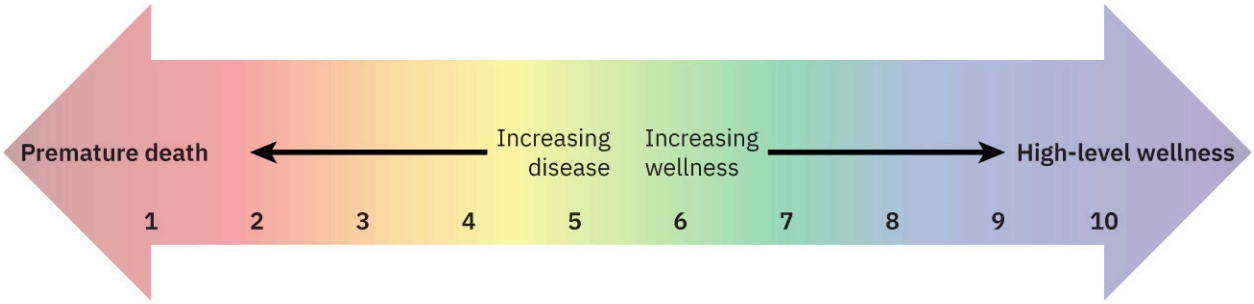

FIGURE 9.4 The wellness continuum illustrates how an individual's wellness may increase or decrease along a scale. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Health care and nursing have begun to prioritize preventive health and self-care, which allows patients to achieve higher levels of wellness along the continuum and results in an overall improved state of health and well-being, despite physical or mental disabilities (Martínez et al., 2021).

Physical Impacts

Many physical barriers can affect the everyday life of individuals with disabilities. Individuals with physical disabilities are often unable to access certain places or resources because they physically cannot get there. This includes situations such as curbs or stairs without ramps, elevators, or other accessible options; lack of automatic doors; poorly lit environments; narrow sidewalks, doors, or aisles; bathrooms or parking spaces that are

inaccessible; and lack of aids to help those with hearing impairment communicate.

Emotional and Mental Impacts

The physical barriers obstructing individuals with disabilities and the impacts of these barriers on a person's wellness are relatively easy to visualize. The emotional and mental impacts of disabilities are often more difficult to envision because they may not be physically present. Nevertheless, the experience of living with a disability, particularly in an unaccommodating or biased society, can have an even more detrimental impact on an individual's emotional and mental well-being. Studies have shown that individuals with disabilities are five times more likely to experience mental distress than those without a disability (CDC, 2023c).

Financial and Social Impacts

In addition to their physical and mental impacts on health, disabilities can also have substantial negative impacts on a person's financial and social well-being. For example, individuals with disabilities are less likely to be employed, which results in an increased risk for living in poverty and experiencing the detrimental health effects associated with low socioeconomic status, such as lack of access to dental care or being unable to afford healthy food options. Individuals with a disability who are employed will likely have to miss work periodically due to their disability, which may affect their income and potentially their employment status if their employer is unwilling to accommodate these absences. In terms of education, people with disabilities are less likely to have completed a high school education, which limits their ability to find employment (CDC, 2023c).

Although unemployment and limited education affect the financial status of the person with a disability, there are also social impacts to consider. Unfortunately, there is a stigma surrounding people with disabilities: society often views them as weaker or "less than" those without a disability. This stigma undoubtedly contributes to the unwillingness of some employers to hire individuals with disabilities and fuels biases within society. Though there has been a recent shift within society to be more inclusive of all people, there continues to be **discrimination**—the unjust or prejudicial treatment of certain people—against individuals with disabilities.

Considerations for Equitable Care among People Living with Disabilities

Though a societal shift toward inclusion and understanding is happening, discrimination toward individuals with disabilities is still common. Discrimination takes place in the workplace, social situations, and many other settings in everyday life. To help eliminate discrimination, the US government has developed several programs that provide funding and other financial resources to individuals with disabilities. An overview of these programs and resources is provided in Table 9.2.

Resource	Overview
Centers for Medicare & Medicaid Services (CMS)	Provides health insurance for low-income individuals with disabilities
Supplemental Nutrition Assistance Program (SNAP)	Helps low-income individuals and families pay for groceries (formerly known as "food stamps")
Temporary Assistance for Needy Families (TANF)	Provides a cash assistance payment program for low-income individuals and families
Social Security Disability Insurance (SSDI)	Pays for health benefits of individuals who cannot work due to medical conditions or disabilities. A person must work for a certain number of years to earn this benefit and be able to use it.

TABLE 9.2 **Federal Resources for Individuals with Disabilities**

Resource	Overview
Supplemental Security Income (SSI)	Provides monthly payments to qualified low-income individuals with a disability
Children's Health Insurance Program (CHIP)	Provides health insurance coverage to uninsured children who live in families that make too much money for Medicaid but cannot afford private health insurance

TABLE 9.2 Federal Resources for Individuals with Disabilities

Children

In addition to the financial resources listed in Table 9.2, legislation has been passed that protects children with disabilities from discrimination. Specifically, the Individuals with Disabilities Education Act (IDEA) ensures that all children with disabilities have access to a free, appropriate public education. This act provides a comprehensive and coordinated approach for implementing early intervention services for infants and toddlers with disabilities to ensure they have the resources they need to be successful in the future. Additionally, this legislation provides the necessary tools and resources to parents and educators of children with disabilities to provide an adequate educational experience regardless of a child's specific disabilities or limitations. This may include certain accommodations or special education programs that are tailored to the child and their specific disability. However, it is important to note that IDEA is severely underfunded, highlighting the need for more advocacy and federal funding on behalf of children with disabilities (Blad, 2020).

Veterans Living with Disabilities

Veterans are another group at higher risk for physical, emotional, and mental disabilities (Figure 9.5). This group has seen a significant increase in suicide rates, indicating the need for thorough mental health assessment and swift intervention if any signs of suicidal ideation are noted (Sheehy & Schwartz, 2021). Several programs have been developed to care for this specific population. Primarily, veterans have access to health care through the Department of Veterans Affairs (VA). Through the VA, eligible veterans can obtain disability compensation: a monthly, tax-free payment to veterans who are unable to work because of a disability acquired during active service. This may help take the financial burden off the veteran with a disability and improve their overall health and well-being. However, this program is underfunded and at risk of being unable to support the growing needs of this population (Shane, 2022).

Another program available to assist veterans with disabilities is the Wounded Warrior Project (WWP). The WWP is a charitable organization that provides resources to veterans after they return home from war or military conflict. These resources include counseling, rehabilitation services, and social support.

FIGURE 9.5 Members of the military, both former and present, often require special services to treat disabilities resulting from their service. (credit: "National Veterans Wheelchair Games 2022" from U.S. Department of Veterans Affairs, /Flickr, Public Domain)

Vocational Programs for Patients with Disabilities

Because a sizable portion of discrimination against individuals with disabilities occurs in the workplace, there has been an increase in the development of vocational programs to help such individuals find and keep employment. Traditionally, these programs have been offered at the state level, so they may vary from state to state in terms of services provided. However, most programs offer employment services such as job training and placement, career counseling, and financial planning. These resources are intended to help individuals with disabilities not only prepare for the hiring process but also keep their job and maintain a consistent employment status.

Americans with Disabilities Act

The Americans with Disabilities Act (ADA), passed in 1990, is a federal law that prohibits discrimination against individuals with disabilities. This law also oversees and mandates that public businesses provide individuals with disabilities an equal opportunity to access services and commercial goods. This is accomplished by ensuring that businesses and workplaces provide reasonable accommodations for those with disabilities. Examples of accommodations for patients with chronic conditions include

- allowing service animals on public transportation and inside businesses
- installing wheelchair ramps and elevator access in place of stairs (Figure 9.6)
- placing handicap parking spaces closer to entrances
- providing sign language interpretation
- providing testing accommodations for individuals with learning disabilities
- providing visual aids to assist with visual impairment
- providing wheelchair-accessible bathrooms

FIGURE 9.6 Ramps allow people in wheelchairs to access buildings whose entrances are not at ground level. (credit: "Access to the ramp in a wheelchair" by Правительство Калининградской области/Wikimedia Commons, CC BY 4.0.)

Nurses with Disabilities

There are nurses with an array of disabilities who can still practice nursing. For example, some nurses who have hearing impairments use special stethoscopes for auscultation. Some nurses leave the bedside due to physical injuries that create permanent disability, but they continue to work in other modalities such as informatics, nursing education, case management, and office work. There are also nurses with emotional and mental disabilities who have accommodations in place to ensure they can perform their duties effectively.

9.4 Access and Barriers to Health Care

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define the common obstacles to health care access for chronically ill patients
- Explain the social and financial considerations for patients with chronic diseases
- Summarize the role of the home care nurse and criteria for patients to receive home care services

Many barriers may limit health care access for individuals with disabilities. These barriers can be financial, geographic, or social, in addition to other external environmental factors. These barriers are closely related to the social determinants of health, which are defined as the conditions in which people are born, work, grow, live, and age (see Figure 2.2) (CDC, 2022b). These determinants can significantly influence not only an individual's access to health care but their general health status as well.

LINK TO LEARNING

Race and ethnicity can have a significant impact on an individual's access to and ability to afford quality health care. This fact sheet (https://openstax.org/r/77disparities) lists data on health disparities for members of various racial ethnic groups.

Access to Health Care

Health care access has been and continues to be an important issue both in the United States and globally. Some individuals, especially those with disabilities and chronic illnesses, may have more difficulty obtaining adequate health care services. This can be due to many factors, including lack of health insurance, low socioeconomic status, limited (or lack of) transportation, geographic location (e.g., patient lives in a rural area without nearby health care services), and work and schedule constraints.

Social and Financial Considerations

Social and financial factors that may influence an individual's ability to access health care include employment status, transportation, and geographic location. Coupled with a chronic illness or disability, these factors become even more complex, making it more difficult to access necessary health care services and manage their illness. For example, members of a lower socioeconomic class may struggle to afford health care or to physically access it due

to geographic remoteness.

Employment

Employment status can contribute to lack of health care access in many ways. First, individuals with chronic illness and disabilities may have limited employment options, forcing them to take lower paying jobs without adequate health insurance coverage. Though employers are required to provide reasonable accommodations because of the ADA, they do not always comply with the law, and government regulators may lack the resources to catch and remedy noncompliance. Additionally, some jobs, such as those involving manual labor, may not be able to provide accommodations that allow for certain individuals to effectively complete the work required. Individuals with severely debilitating chronic conditions may not be able to work at all.

Some individuals may have to take lower-paying jobs and end up living in poverty, making it nearly impossible to afford health insurance or pay for health care services out of pocket. Additionally, many of the job opportunities available to individuals with disabilities are only offered part-time and, therefore, do not provide benefits such as health insurance coverage. This further reduces health care access because these individuals are unable to pay for their own private insurance or afford out-of-pocket costs for services. Though there are financial resources available for these individuals (as shown in Table 9.2), they often do not receive enough assistance and are unable to afford adequate health care.

Transportation

A lack of, or limited access to, transportation is another factor that can negatively affect health care access. Findings from a 2020 national survey show that 5.8 million Americans annually delay health care because they do not have transportation (Wolfe et al., 2020). This survey also determined that individuals living in poverty and those with chronic health conditions are disproportionately affected. This factor is compounded when many individuals with disabilities cannot use public transportation options. The ADA requires reasonable accommodations, including public transportation, but the provided accommodations are not always adequate to allow all people with disabilities to use them. This inadequacy of resources is related to multiple factors, including a lack of funding and the wide diversity of disabilities experienced in society. There may also be other constraints, such as the financial cost of taking public transportation, limited routes that do not service certain places, or limited schedules that do not coincide with an individual's availability.

The private sector has made some efforts to address this problem. For example, modern vehicles are increasingly built with adaptive equipment, including greater integration of hand controls and assistance straps, and ramps for exiting and entering the vehicle (National Highway Traffic Safety Administration, n.d.). However, more is needed. Federal legislation to expand the availability of low-cost transportation has been discussed over the past several years but is still being developed (Federal Transit Administration, 2023). Until major improvements are made to increase access to public transportation throughout the United States, this remains a major barrier for many people, especially those with chronic conditions and disabilities.

Residence (Geographic Location)

Geographic location is another factor that can affect an individual's access to health care. Just as with a lack of transportation, living too far away from health care facilities can decrease an individual's ability to obtain necessary services. An additional challenge in rural areas is the lack of the appropriate health care specialists. Partly to address this problem, there has been a shift in recent years to use more telehealth, which refers to the provision of health care remotely via telecommunication devices and technology. Insurance plans are increasingly providing coverage for telehealth services (US Department of Health and Human Services, 2023). Unfortunately, they are not always appropriate or practical, because not all individuals have access to high-speed Wi-Fi or other necessary technology for telehealth. Furthermore, not every medical service or procedure can be administered remotely. Even so, for individuals who lack convenient, in-person access to health care providers, the use of telehealth can be quite beneficial.

Self-Care and Personal Assistance

Another factor that can influence health care access is related to the individual's ability to perform self-care and the degree of personal assistance they require from others. Although some people with disabilities and chronic conditions can live independently or with family members, others may reside in skilled nursing facilities or other assisted living institutions, where they require extra help in performing ADLs and getting to and from appointments.

This makes health care access more difficult because these individuals may have to rely on others to take them to their appointments or to interpret or implement their treatment plan. Most assisted living facilities have programs in place to help with these needs, but many facilities are short-staffed, and caregivers are not always able to effectively assist patients with their health care needs (Heiks & Sabine, 2022).

This factor becomes even more complex when you consider that many individuals with disabilities are still living on their own at home and do not have access to caregivers or other services that would be provided in a facility setting. These individuals often must rely on family or friends for transportation or other help, which can be a significant barrier to health care access.

Home Care

Although some people with disabilities are unable to work, those with severe, debilitating disabilities may not even be able to leave their homes. In these situations, home nursing care may be required, but certain criteria must be met first. These criteria will vary slightly depending on the agency providing the care and the patient's insurance. For example, Medicare has the following requirements for home care (CMS, n.d.):

- leaving the home is not recommended because of the patient's condition (e.g., severe immunocompromised)
- leaving the home requires major effort
- patient has trouble leaving the home without assistance (e.g., walker, cane, wheelchair, crutches, special transportation) because of substantial illness or injury

Medicare covers the following home care services, though some benefits are temporary or require patients to meet certain criteria:

- medical equipment and supplies for use at home
- medically necessary skilled nursing and/or home aide care
- medication administration
- physical and occupational therapy
- social services
- speech-language pathology services

LINK TO LEARNING

Reimbursement for home care services from Medicare and Medicaid requires strict criteria for patients to qualify for the service. The Outcome and Assessment Information Set (OASIS) tool was created in 1999 and has been proven to be a reliable and valid instrument to determine reimbursement. The tool collects subjective and objective data on the patient's disease profile; physical, psychological, and psychosocial functioning; and living arrangements. The assessment is conducted at the initial intake visit when a patient is seen for home care (CMS, 2023). Visit this manual (https://openstax.org/r/77oasis) for more information about the OASIS.

Level of Skilled Care Required

It is important to note that patients with chronic illness and disability who are admitted to an inpatient setting for care will require an evaluation before discharge to determine the appropriate level of care after leaving the hospital. Often, patients with disabilities have been living at home alone, but after assessment in the hospital, they are determined to be unsafe in the home setting and to require a higher level of care, such as home health care or transfer to an assisted living or rehabilitation facility.

For example, many older adult patients living with musculoskeletal disabilities related to age have been living alone but are brought to the hospital after a fall or other injury. While in the hospital, a discharge evaluation is performed in which the safety of the patient being returned to their prior living situation is assessed. This evaluation process is conducted by care providers from many different disciplines, including medicine, nursing, and physical and occupational therapy. After determining what level of care the patient will require upon discharge, an interdisciplinary team, usually led by social services, works to find the patient the necessary resources to obtain this level of care. The main goal of the interdisciplinary team is to ensure safe patient discharge.

9.5 Prevention of Chronic Disease

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe modifiable and healthy lifestyle practices to prevent chronic disease
- Discuss the recommended preventive health screenings in diagnosing chronic disease
- Summarize secondary and tertiary prevention strategies in the management of chronic disease

Though some chronic diseases occur regardless of lifestyle choices, many are entirely preventable, or at least may be limited in severity, with the implementation of healthy lifestyle changes. Even if lifestyle changes cannot entirely prevent a disease, they may slow its progression and promote the highest quality of life possible while living with a chronic health condition. These lifestyle modifications are categorized into three levels of prevention: primary, secondary, and tertiary (Figure 9.7).

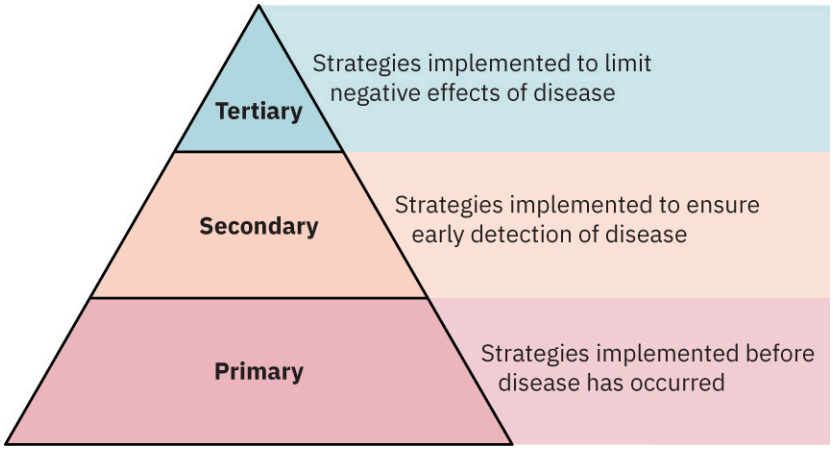

FIGURE 9.7 Chronic disease prevention occurs in three levels: primary, secondary, and tertiary. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Primary Prevention

Strategies that aim to prevent disease from occurring in healthy individuals can be identified as primary prevention. These interventions are implemented as health promotion strategies in the hope that the person will never develop chronic illness. Examples of primary prevention strategies include

- diet and exercise programs
- distribution of condoms and cervical diaphragms to prevent pregnancy or sexually transmitted diseases
- immunizations
- needle-exchange programs
- pre-exposure prophylaxis for HIV
- smoking cessation programs

Exercise

It is common knowledge that exercise is beneficial for overall health, but what is less well known is that consistent exercise has been linked to a lower risk of developing chronic health conditions such as type 2 diabetes, heart disease, dementia, certain cancers, and depression (CDC, 2023b). The CDC recommends that adults perform moderate-intensity aerobic exercise for at least 150 minutes per week, plus isometric muscle-strengthening exercises at least two days per week. Examples of moderate-intensity exercises include walking, running, biking, dancing, and gardening.

Lifestyle Choices

In addition to exercising consistently, other lifestyle choices have been linked to a decreased risk of chronic disease development. Smoking tobacco and vaping are risk factors for many chronic illnesses, so smoking cessation is one of the most important lifestyle modifications for preventing disease. Additionally, overconsumption of alcohol has been shown to increase the risk of chronic disease development, so it is recommended that adults consume alcohol in moderation: defined as two or fewer drinks in a day for a man and no more than one drink per day for a woman.

Other important lifestyle choices for preventing the development of chronic disease include getting adequate sleep each night, limiting stress, and maintaining social connectedness with others.

Healthy Eating

Diet is another factor that can be used as a primary prevention strategy for chronic disease. The typical American diet is high in processed food, fats, and sugar, increasing the risk of CVD, diabetes, and many other chronic conditions. Consuming a healthy diet significantly decrease the risk of chronic disease development (Kimokoti & Millen, 2016). Current recommendations include a diet that is high in the following foods: fruits, low-fat dairy products, nuts and seeds, omega-3 fatty acids, vegetables, and whole grains.

Additionally, current dietary recommendations suggest limiting intake of refined grains, sugary and salty foods, and processed snack items.

Secondary Prevention

Approaches aimed at the early detection of disease are called secondary prevention strategies. The hope is that by detecting the condition early, the damage from the disorder will be limited and interventions can be implemented right away. Examples of secondary prevention strategies include regular physical examinations and screenings for specific medical conditions.

Chronic Disease Screenings

For each chronic disease, there are specific screening guidelines and recommendations based on age, gender, genetics, and other demographic factors. Some of these screening recommendations are listed in Table 9.3.

Condition	Screening Recommendations
Breast cancer	• Annual mammograms should begin at age 40 years. • After age 55 years, mammograms can be performed every other year. • Guidelines may change slightly for individuals at increased risk for cancer due to family history or certain genetic mutations (e.g., in the *BRCA1* gene) (American Cancer Society, 2022).
Cervical cancer	• A human papillomavirus test is recommended every 5 years for females aged 25–65 years. • A Pap smear is recommended every 3 years (American Cancer Society, 2021).
Colorectal cancer	• Beginning at age 45 years, individuals at average risk should receive a colonoscopy every 10 years; earlier or more frequent screenings are recommended for those at higher risk due to family history or genetic factors. • Regular screenings should be continued through to at least age 75 years (if the individual is expected to live at least 10 more years) (American Cancer Society, 2023).
Diabetes	• Screening for type 2 diabetes should be performed annually in overweight and obese individuals OR in individuals aged 40–70 years (American Academy of Family Physicians, n.d.).

TABLE 9.3 Screening Recommendations for Chronic Conditions

Condition	Screening Recommendations
Hyperlipidemia	• A lipid panel should be completed every 4–6 years for healthy adults. • More frequent (typically annual) lipid panels should be completed for individuals at high risk due to factors such as genetics, family history, and poor diet (CDC, 2024).
Hypertension	• The US Preventive Services Task Force (USPTSF) recommends screening all adults who are older than 18 years and who do not have diagnosed high blood pressure. • Adults older than 40 years and those at increased risk for high blood pressure should be screened annually (US Department of Health and Human Services, 2021).

TABLE 9.3 Screening Recommendations for Chronic Conditions

Family Genetics

Many chronic conditions are associated with a family history. Individuals with a strong family history of certain chronic conditions may be advised to obtain genetic tests or counseling to see if they also possess genetic mutations that would increase their risk of developing the disorder. Individuals with such risk factors should be screened for the disorder earlier and more frequently than those without the additional risk factors.

Tertiary Prevention

Care approaches implemented after an individual has been diagnosed with a chronic disease are called tertiary prevention strategies. These strategies aim to limit the negative effects of the condition and allow the person to have the highest quality of life possible despite their chronic illness. Tertiary prevention strategies include physical and occupational therapy, rehabilitation services, and symptom control (e.g., medications, follow-up appointments).

INTERDISCIPLINARY PLAN OF CARE

Interdisciplinary Team for Patients with Chronic Illness

- Primary care provider (PCP): the main point of contact for the patient's health care needs and helps coordinate care
- Specialists (e.g., cardiologist, endocrinologist): provide specialized management of chronic conditions, including diagnosis and overseeing treatment
- Nurses: provide direct patient care, coordinate care with other providers, and educate patients and families about the management of chronic disease
- Pharmacists: ensure safe and effective medication management, including medication reconciliation, reviewing medication regimens for potential adverse effects, and providing patient education on medication use and adherence
- Physical therapists: help patients improve mobility, strength, and function through exercises
- Occupational therapists: help patients in regaining independence with ADLs
- Nutritionists and registered dietitians: provide nutritional assessment, counseling, and education to help patients manage chronic conditions through diet and lifestyle modifications
- Social workers: assist patients and families navigate the health care system, access resources, address psychosocial needs, and coordinate care across multiple providers and settings
- Home health aides (or nurses): provide assistance with ADLs, personal care, and light household tasks for patients who require support at home due to chronic illness or disability
- Case managers: coordinate care across various health care settings, ensuring continuity of care, assisting with discharge planning, and advocating for the patient's needs and preferences

9.6 The Chronic Care Model

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define the Chronic Care Model and its components
- Explain the role that clinical information systems play in the Chronic Care Model
- Identify overarching goals of the Chronic Care Model

Because chronic diseases are associated with such high morbidity and mortality rates, it is important to prevent them from developing when possible. As a result, there has been a recent shift of focus to preventive medical and nursing care as opposed to the treatment of illnesses after diagnosis (Healthy People 2030, n.d.). Coinciding with this new focus, the Chronic Care Model was developed to guide the prevention, management, and treatment of chronic disease.

The Chronic Care Model

The **Chronic Care Model** was developed as a guide for the reorganization of health care delivery to effectively care for patients with chronic conditions. It has been used by many health care organizations to redesign their structure to focus on proactive prevention as opposed to reactive treatment of disease. At its core, the model emphasizes the role that health care organizations play within the larger community. When a community's health system is functioning effectively, proactive health care teams and informed patients have productive interactions that achieve the goals of everyone in the system.

LINK TO LEARNING

See Figure 1 in this article published in the *Delaware Journal of Public Health* (https://openstax.org/r/77chroniccare) for a graphic representation of the Chronic Care Model.

Health Care Organization

Organization of the health care system is the foundation of the Chronic Care Model. Without appropriate organization and structure, the health care system would be unable to provide effective care for chronic illness. This area of the model includes four components: self-management support, delivery system design, decision support, and clinical information systems.

Self-Management Support

Self-management support refers to the assistance that patients with chronic illness need day to day. Specifically, this includes supports such as the extension of education about the chronic disease and an individualized program to assist individuals to manage their chronic diseases. For example, patients with diabetes often have individualized programs to monitor their blood glucose levels over time. These programs usually involve recording their glucose levels so a care team can review them and make personalized recommendations about medications and other interventions. It is also important to support goal development and increase problem solving to manage chronic diseases with the assistance of health care staff (Agency for Healthcare Research and Quality, 2014). For example, for patients with hypertension, the provider or other health care staff may assist the patient in setting a mutually agreed-upon goal such as limiting sodium intake to 1,000 mg/d. The care team would then help the patient figure out strategies to use to achieve this goal, using problem solving to come up with solutions to accomplish the goal.

Delivery System Design

The delivery system design portion of the Chronic Care Model involves the design of the care provided. This area ensures that effective, efficient care is provide. Important aspects of this component of the model include the following:

- defining roles of various health care team members
- ensuring regular follow-up by the care team through a variety of methods, including telephone calls, home visits, and clinic appointments
- providing case management for complex patient cases
- using evidence-based care in practice

Decision Support

The decision support component of the Chronic Care Model refers to the implementation of evidence-based guidelines into practice (Accelerating Care Transformation [ACT Center], n.d.). This can be done both in the clinic and inpatient settings. Essentially, when a nurse or other provider is caring for a patient with a chronic disease, they should be able to quickly pull up a system or database of information, including best practice guidelines, that can assist them in the treatment and management of the condition. This is especially helpful to effectively care for the patient when providers are not as familiar with a condition or are unsure about how to manage it.

Clinical Information Systems

Clinical information systems serve multiple purposes to help providers understand the medical composite of a patient or an aggregate group, as well as understand and manage preventive care for individuals with chronic diseases. With the sophistication of electronic medical records, the benefits of these systems aid in guiding treatment, identifying problems, and gauging progress of a chronic disease. (ACT Center, n.d.). Other aspects of this part of the model include

- facilitating individual patient care planning
- monitoring the performance of the care team and patient outcomes
- providing clinicians an inclusive list of patients with a specific chronic disease from which they can monitor patient health status over time
- sharing information with patients and providers to allow for smooth transitions and better coordination of care

Community

Community is the other large, foundational component of the Chronic Care Model. The synergism of community and chronic conditions facilitates prevention strategies. Medical facilities in the community are not in solidarity; rather, they form alliances with schools, spiritual or faith-based organizations, businesses, state and local programs, and other interested and impacted parties in the community. The goal of the relationship with these organizations is to ensure that the community remains involved in the ongoing care of its individuals.

Overarching Goals of the Chronic Care Model

The Chronic Care Model aims to improve the quality of care provided to patients with chronic disease to ensure optimal patient outcomes. The foundational goal of the model is to transform health care delivery systems so they are better equipped to provide quality care. The main overarching goals of the model include

- enhancing patient self-management: empowering patients with knowledge, skills, and resources needed to make informed decisions, adhere to treatment plans, and engage in healthy lifestyle behaviors
- fostering patient-centered care: promoting shared decision-making, patient education, and support for patients' psychosocial and emotional needs
- improving patient outcomes: reducing complications, improving symptom management, enhancing quality of life, and optimizing functional status
- improving population health: addressing social determinants of health, promoting healthy behaviors, and implementing population-level interventions
- increasing health care access: ensuring appropriate access to primary care, preventive services, medications, and community support programs
- optimizing use of health care resources: reducing unnecessary hospitalizations and emergency department visits.
- promoting care coordination: communication, collaboration, and information sharing among health care team members.

9.7 Care of the Chronically Ill Patient

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Summarize important subjective assessment questions for patients with chronic illness
- Discuss interprofessional collaboration team members through the assessment
- Identify cues to recognize and analyze for patients with chronic illness
- Plan hypotheses to prioritize and generate solutions for patients with chronic illness

Nursing care for a patient with a chronic illness is unique and challenging related to changes in the acuity of the chronic disease itself. For example, inpatient admissions may be required due to an **acute exacerbation**, or sudden worsening of symptoms, of a chronic disease (e.g., acute-on-chronic heart failure). In these situations, caring for patients with acute illness also requires care of the chronic diseases that afflict the patient simultaneously. The nurse must provide patient-centered care and focus management and treatment strategies specific to the patient's needs and preferences. This section details the various components of care for patients with chronic illness.

Subjective Interview of the Patient with Chronic Illness

The assessment of a patient with a suspected or diagnosed chronic illness begins with obtaining a full subjective history and patient interview. This interview is like a typical patient history but with questions that are more focused on the specific chronic illness. For example, when assessing a patient with suspected diabetes mellitus, some of the focused questions may include

- Are you experiencing any symptoms, such as frequent urination or thirst?
- Do you ever feel lightheaded? If so, does this condition improve after eating?
- Do you have a family history of diabetes?
- Have you experienced any weight gain or loss?
- Have you had your blood glucose levels checked recently?

Questions during the subjective interview should focus on common symptoms associated with chronic illness. Asking these questions can help indicate whether the individual may have the illness and whether further testing and follow-up are necessary. These questions may also indicate improvement or worsening of the patient's chronic conditions. For patients admitted with acute exacerbations of the underlying chronic disease, it is important for the nurse to assess for any knowledge deficits the patient may have about their condition. In many cases, patients do not know enough about their chronic disease or have enough interdisciplinary support to manage it at home. In these cases, the nurse should ask the patient questions about what they know about their condition, what treatment (if any) that they are currently receiving, and what resources they have available for managing their condition. After gathering this information, the nurse will have a better understanding of the patient's knowledge level and can tailor their plan of action accordingly.

Interprofessional Collaboration

As with most patient care, caring for a patient with a chronic illness involves an interdisciplinary team approach. Collaboration between members of the health care team has been shown to improve patient outcomes and ensure that the patient receives thorough, high-quality care (Pannick et al., 2015). Table 9.4 lists typical members of the health care team and their roles.

Team Member	Roles
Provider	Performs assessments and guides implementation of the treatment and management of the chronic disease; may be a physician or a nurse practitioner
Nurse	Coordinates care, performs assessments, implements treatment interventions, evaluates care, and serves as an educator and counselor when necessary
Social worker	Ensures the patient has appropriate financial and community resources to effectively care for their chronic condition
Physical and/or occupational therapist	Works with patient to ensure optimal physical condition and performance of ADLs so the patient can maintain the best quality of life possible, despite their condition

TABLE 9.4 Interprofessional Team Members for Patients with Chronic Illness

Team Member	Roles
Dietitian	Counsels patient and implements dietary plan to promote healthy eating habits to prevent disease or limit its negative effects
Pharmacist	Coordinates prescriptions to ensure patient is receiving correct medications and dosages for their condition and symptoms

TABLE 9.4 Interprofessional Team Members for Patients with Chronic Illness

Recognize Cues

One of the most important aspects of nursing care for a patient with a chronic illness relates to assessment and recognizing cues. If the patient has not yet been diagnosed with a chronic disease but it is suspected, the nurse must be able to recognize changes in the patient's condition that may indicate the patient has the disease. If the patient has already been diagnosed with a chronic condition, the nurse should be able to recognize symptoms that would indicate the condition is worsening or improving. A comprehensive interview incorporating subjective data (e.g., patient- or family-reported data) and objective data (e.g., changes in vital signs) lends itself to using multiple recognized cues in understanding the impact of chronic disease.

Analyze Cues

After assessing symptoms related to the chronic condition, the nurse must determine the next step. Often, this involves suggesting further diagnostic testing to confirm the suspected diagnosis. Chronic disease progression is often identified in this step of the clinical judgement measurement model. By analyzing cues, the nurse is linking the patient's medical history with the cues initially identified. For example, a patient with diabetes mellitus who reports fatigue and increased hunger and thirst may trigger the nurse to review the medical history and search for the presence of diabetes mellitus. The nurse may perform a medication reconciliation and learn that the patient takes insulin therapy, indicating the existence of a chronic metabolic endocrine disorder.

Prioritize Hypotheses

Prioritizing hypotheses involves organizing the assessment data collected previously and determining what the priority issues are that require intervention. If the patient's chronic condition has become life-threatening, implementing life-saving measures is the top priority. After that, the nurse may use other models, such as Maslow's hierarchy of needs, to determine the priorities of care.

Generate Solutions

Once the priorities for the patient have been established, the planning process begins. The nurse collaborates with the care team—which includes the family and support team—to determine appropriate outcomes for the patient based on their needs. The team uses evidence-based practice guidelines to ensure that appropriate interventions are implemented to achieve optimal outcomes. Goals are developed—using simple, measurable, attainable, realistic, and timed criteria—to evaluate the effectiveness of nursing care. For example, the nurse may elect to have the patient show competence in performing a blood glucose check with return demonstration. The solution generated, ultimately, would be for the patient to monitor their chronic diabetes mellitus correctly.

Take Action

When taking action, nursing interventions are individualized for the patient and supported by evidence-based practice. In the example of the patient with diabetes, the nurse ensures blood glucose monitoring is being done competently and that the patient self-administers the ordered insulin therapy correctly. The nurse also provides education about the complications of untreated diabetes mellitus. Interventions are focused on chronic disease and tailored to the patient.

Evaluate Outcomes

After implementation of the care plan, the nurse will evaluate outcomes. The nurse should assess not only whether the outcomes have been met but also which priorities of care need further intervention. If it is determined that the outcomes were not met, the nurse is tasked with coordinating revisions to the plan of care to address the unmet outcomes. This often involves getting the interdisciplinary team together again to make changes to the plan of care

that better address the patient's needs. For patients with diabetes, for example, nurses may have to ensure there is laboratory surveillance of hemoglobin A_{1c}, follow up for chronic monitoring with foot care, and provide ongoing support for nutritional education. Given the longevity of chronic disease, nurses must consistently evaluate the patient's response to the chronic disease.

Summary

9.1 Chronic Disease and Illness (Prevalence and Etiology)

- Chronic diseases and illnesses affect more than half of the population and are the leading cause of death and disability in the United States.
- Chronic disease is defined as a medical or health problem that lasts at least 1 year and requires ongoing medical attention or limits ADLs, whereas chronic illness refers to the human experience of living with a chronic disease.
- Age, gender, and culture are three demographic factors that can significantly impact how an individual copes with a chronic medical condition.
- It is imperative that nurses provide patient-centered care that considers the specific preferences and needs of the patient diagnosed with a chronic disease.

9.2 Comorbid Chronic Diseases

- More than one-fourth of individuals with chronic illness are diagnosed with comorbidity, or the presence of two or more chronic conditions simultaneously.
- Having chronic comorbidities increases disease burden and affects many aspects of health care including finances and health insurance coverage.
- Polypharmacy often occurs because of comorbid chronic conditions and can result in negative outcomes, including adverse medication reactions and overdoses.

9.3 Chronic Illness and Disability

- Disabilities, or limitations in function or performance of everyday activities, occur often because of chronic illness.
- Wellness exists on a continuum, so even with a chronic disease, individuals may still fall somewhere on the high end of the wellness continuum if they ensure they are improving other aspects of health beyond just physical health.
- There are many barriers—including physical, emotional, mental, social, and financial—that negatively affect the health of individuals with disabilities.
- The Americans with Disabilities Act (ADA) is aimed to prevent discrimination against individuals with disabilities and mandates that “reasonable accommodations” must be provided in the workplace and on public transportation to allow individuals with disabilities to have equal access to services and opportunities.

9.4 Access and Barriers to Health Care

- There are many barriers that may limit health care access for individuals with disabilities, including social and financial factors, such as employment status, as well as access to transportation and geographic location.
- Although some people are not able to work because of their disabilities, others who have severe, debilitating disabilities may not be able to leave their homes; they may require home nursing care.
- Patients with chronic illness and disability who are admitted to the inpatient setting for care require an evaluation before discharge to determine the appropriate level of care and a safe discharge to home after leaving the hospital.

9.5 Prevention of Chronic Disease

- Though some chronic diseases occur regardless of lifestyle choices, many are preventable or may be limited, at least, in severity with the implementation of healthy lifestyle changes.
- Primary prevention strategies aim to prevent a disease from occurring in healthy individuals and include interventions such as immunizations, exercise, and healthy lifestyle modifications.
- Secondary prevention strategies are aimed at the early detection of disease and include regular physical examinations and screenings for specific medical conditions.
- Tertiary prevention strategies are implemented after an individual has been diagnosed with a chronic disease. These strategies aim to limit the negative effects of the condition and allow the person to have the best quality of life possible despite their chronic illness.

9.6 The Chronic Care Model

- The Chronic Care Model was developed to guide the prevention, management, and treatment of chronic disease. It consists of two main components: the organization of health care and the resources and policies of the community.
- Within the organization of health care, one component is self-management support. This identifies the required services an individual requires to cope with their chronic disease.
- Within the organization of health care, another component is delivery system design. This encompasses the partnership with the health care team and the individual with the chronic disease, as well as the importance of follow-ups.
- Within the organization of health care, the third component is decision support. This is defined by the evidence-based interventions in managing chronic diseases.
- Within the organization of health care, the final component is clinical information systems. These aid in understanding the health or chronic disease of an individual or aggregate.
- The overarching goals of the Chronic Care Model include improving patient outcomes, enhancing patient self-management, increasing health care access, promoting care coordination, optimizing use of health care resources, fostering patient-centered care, and improving population health.

9.7 Care of the Chronically Ill Patient

- Nursing care of a patient with a chronic illness is like that of any other patient, but with more focus on the specific chronic condition itself.
- The nurse must provide care that is patient-centered and focuses on management and treatment strategies specific to the patient's needs and preferences.
- Collaboration between members of the interdisciplinary health care team improves outcomes for patients with chronic conditions and ensures the patient receives thorough, high-quality care.

Key Terms

acute disease illness that develops quickly and lasts a relatively short period of time
acute exacerbation sudden worsening of symptoms of a chronic disease
Chronic Care Model model developed to guide the reorganization of health care delivery to effectively care for patients with chronic conditions
chronic disease medical or health problem that lasts one year or more and requires ongoing medical attention or limits activities of daily living
chronic illness human experience of living with a chronic disease
comorbidity simultaneous presence of two or more medical conditions
disability limitation in function or performance of everyday activities
discrimination unjust or prejudicial treatment of certain people, especially related to characteristics such as ethnicity, sex, age, or disability
disease burden total effects of a disease on an individual or a society
polypharmacy simultaneous use of multiple medications by a single patient

Assessments

Review Questions

1. What is an example of a chronic disease?
    a. influenza
    b. asthma
    c. chicken pox
    d. contact dermatitis

2. What eligibility requirement must be met for an individual to be able to receive health insurance coverage for chronic disease with Medicaid?
    a. being older than 65 years

b. having a disability
c. meeting a specific low-income threshold
d. being diagnosed with end-stage renal disease

3. What statement best reflects the economic impact of chronic illness in the United States?
a. Chronic illness primarily affects personal finances but has minimal impact on the broader economy.
b. The number of diagnosed chronic conditions has no correlation with health care expenditures or use of health care services.
c. Americans diagnosed with five or more chronic conditions represent a small percentage of the population and health care spending.
d. Increasing numbers of diagnosed chronic conditions correlate with a significant economic burden on both individuals and the health care system.

4. What is an example of a cognitive disability?
a. difficulty walking
b. complete deafness
c. inability to concentrate
d. difficulty performing ADLs

5. What criteria is a requirement for home nursing care according to Medicare guidelines?
a. The patient must be deaf or blind.
b. The patient must be unable to work.
c. The patient has trouble leaving the house without a wheelchair.
d. The patient can leave the home but does not have any transportation.

6. What is a secondary prevention strategy for cervical cancer?
a. eating a healthy diet
b. getting an annual mammogram
c. exercising for 30 minutes daily
d. having a Pap smear every 3 years

7. What is the recommended weekly amount of exercise for the prevention of chronic disease?
a. 100 minutes
b. 120 minutes
c. 150 minutes
d. 200 minutes

8. What action is recommended for the early detection of breast cancer?
a. Annual mammograms should begin at age 40 years.
b. Annual mammograms should begin at age 55 years.
c. Mammograms should be performed every 10 years.
d. Regular mammograms may be stopped after age 65 years.

9. What aspect of the Chronic Care Model involves use of a registry for tracking patient information?
a. decision support
b. delivery system design
c. self-management support
d. clinical information systems

10. What is the overall goal of the Chronic Care Model?
a. identifying patient follow-up needs
b. giving the patient information about their condition
c. developing relationships with community partners

d. facilitating productive interactions between patients and providers

11. The nurse is caring for a patient with CVD. What aspect of nursing care represents the "generating solutions" aspect of the clinical judgment model?
    a. assessing pitting edema in the legs
    b. asking the patient about their medical history
    c. turning the patient manually every 2 hours
    d. recommending the patient change dietary habits

Check Your Understanding Questions

1. What is the difference between chronic disease and chronic illness?
2. Give an example of two chronic diseases and explain why they might occur together.
3. How does the SNAP help ensure that patients with disabilities receive equitable care?
4. A nurse is caring for an older adult patient who presents to the hospital after a fall and hip fracture at home. The patient reports being unable to afford her medications and not having a car to get them refilled. What obstacles to health care access does this patient have?
5. What social or financial assistance programs could the nurse recommend to a patient who recently lost their job and is worried about being able to afford housing and food?
6. What are some lifestyle modifications you could suggest to a patient at high risk for developing CVD?
7. Explain the purpose of the Chronic Care Model.
8. Identify some important questions to ask a patient with suspected breast cancer during the subjective interview.

Reflection Questions

1. Based on your personal clinical experiences, what are some ways that demographic factors could possibly influence chronic illness?
2. What does the phrase "wellness exists on a continuum" mean in the context of people with disabilities?

What Should the Nurse Do?

Mrs. Harden, a 72-year-old female, visits the orthopedic clinic complaining of recurrent fractures and worsening back pain. She recently moved to the area to be closer to her family. Mrs. Harden has a medical history significant for osteoporosis, which was diagnosed 5 years ago. Other past medical history includes hypertension, COPD, and a COVID-19 infection 3 weeks ago. Her recent dual-energy X-ray absorptiometry (DEXA) scan indicates a significant decrease in bone density. On examination, her vital signs are stable, with a blood pressure of 130/80 mm Hg, heart rate of 78 beats per minute, and respiratory rate of 18 breaths per minute. Mrs. Harden reports difficulty with daily activities due to pain and concerns about her increased fracture risk.

1. What chronic diseases is Mrs. Harden currently diagnosed as having?
2. Given Mrs. Harden's history, what demographic factors does the nurse hypothesize are contributing to her current condition?

Mrs. Dickinson, a 55-year-old female, presents to the primary care clinic with complaints of persistent joint pain, stiffness, and difficulty moving. She reports a history of rheumatoid arthritis diagnosed 10 years ago, which has gradually progressed, leading to reduced mobility and increased reliance on assistive devices. Mrs. Dickinson's vital signs include a blood pressure of 130/80 mm Hg, heart rate of 82 beats per minute, respiratory rate of 18 breaths per minute, and oxygen saturation of 98% on room air. She expresses frustration with her declining ability to perform ADLs independently.

3. What disease does Mrs. Dickinson have and how does it contribute to disability?
4. Considering Mrs. Dickinson's frustration and reduced independence, what interventions or solutions could you propose to enhance her ability to perform ADLs and improve her overall well-being?

Mr. Kumar, a 30-year-old male, visits the primary care clinic with complaints of worsening shortness of breath, coughing, and chest tightness. He reports a medical history of asthma diagnosed in childhood, with occasional symptoms controlled by rescue inhalers. Recently, Mr. Kumar notes increased frequency and severity of symptoms, especially during the night. He denies any recent illnesses or changes in his medication routine. Vital signs reveal a respiratory rate of 24 breaths per minute, heart rate of 90 beats per minute, and oxygen saturation of 94% on room air. Mr. Kumar expresses concern about the impact of his symptoms on his daily activities and overall quality of life.

5. How would you analyze Mr. Kumar's vital signs, especially the respiratory rate and oxygen saturation, in the context of his reported symptoms and history of asthma?
6. Considering Mr. Kumar's vital signs and reported symptoms, what immediate actions would you take to address his asthma exacerbation during the clinic visit?
7. The nurse begins to assist with care coordination for this patient and makes a list of interdisciplinary team members who should be on the care team. Whom should the nurse include on this list?

Competency-Based Assessments

1. Compare and contrast the immediate impact of acute disease and the long-term impact of chronic illness on a patient's overall well-being. How do these impacts differ, and what considerations should a nurse keep in mind when caring for patients experiencing both acute and chronic conditions simultaneously?
2. How can age-related factors influence the impact of chronic disease on older adults? Consider cognitive changes, physical limitations, and social aspects.
3. As a nursing student, you are working with a patient who has been diagnosed with heart failure and has difficulty accessing services due to limited access to public transportation. How might the patient's limited access to health care affect the management of his chronic condition, and what strategies could the health care team use to overcome these obstacles?
4. Summarize the role of a home care nurse in supporting patients with chronic illnesses. How might the home care nurse address obstacles to health care access, considering both social and financial aspects?
5. As a nurse, how would you address a patient's reluctance to undergo recommended health screenings? What communication strategies would you use to emphasize the importance of early detection?
6. Discuss potential barriers to the implementation of tertiary prevention strategies in the community. How can nurses overcome these barriers and facilitate effective, ongoing care for individuals with chronic diseases?

CHAPTER 10

Fluid, Electrolyte, and Acid-Base Imbalances

FIGURE 10.1 This picture illustrates severe pitting edema of the hands that is likely related to a fluid or electrolyte imbalance. (credit: "Edema Hands 01" by Wang et al./*BMC* Cancer, CC BY 2.0)

CHAPTER OUTLINE

INTRODUCTION The balances of fluids, electrolytes, acids, and bases all play key roles in maintaining the body's physiological processes and overall metabolism. Disturbances to any of these components are common and occur with several different medical conditions. If left untreated, such imbalances have the potential to negatively affect multiple body systems and even cause death. Therefore, it is critical for all nurses, regardless of their area of practice or patient population, to be knowledgeable about appropriate treatment and management of fluid, electrolyte, and acid-base imbalances.

10.1 Maintaining Homeostasis

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain how the components and movement of fluids within the body contribute to homeostasis
- Describe the role of the kidneys, lungs, and endocrine glands in homeostasis

In a healthy body, physiological processes exist to maintain a state of internal equilibrium. If too much of one chemical accumulates, the body can remove the excess chemicals and restore balance. This relatively stable internal state is called homeostasis.

The body must maintain appropriate balances of various fluids, electrolytes, pH, acids, and bases to maintain homeostasis. The body uses several mechanisms to compensate for natural imbalances, including those within the renal, respiratory, and endocrine systems. However, these compensatory mechanisms have limits, and the body can no longer compensate effectively in some conditions. In these cases, medical and nursing interventions may be required to assist the individual in re-establishing the body's homeostasis. This chapter will focus on how the balance of fluid and electrolytes and acid-base balance contribute to the maintenance of homeostasis.

Fluids in the Body

The body's balance of fluids, electrolytes, pH, acids, and bases are determined by chemistry. Nurses must familiarize themselves with several foundational concepts to treat patients with an imbalance. Specifically, nurses should understand the components and regulation of body fluids and the characteristics of the different homeostatic compensatory mechanisms in the body. With a solid foundational knowledge of these concepts, nurses will better understand the pathophysiologic changes occurring in the body and possess the skills to intervene and provide appropriate and timely patient care.

Composition of Fluids

To comprehend the medical significance of fluid imbalances, it is important first to have a general understanding of the overall fluid composition in the body. Body fluids consist of water, electrolytes, proteins, blood plasma and component cells, and other soluble particles, each of which is called a **solute**. These fluids are found in two main areas of the body: intracellular and extracellular compartments. Figure 10.2 illustrates these compartments. Table 10.1 describes the characteristics of both intracellular and extracellular fluid compartments. Note there are three subtypes, or spaces, of extracellular fluid.

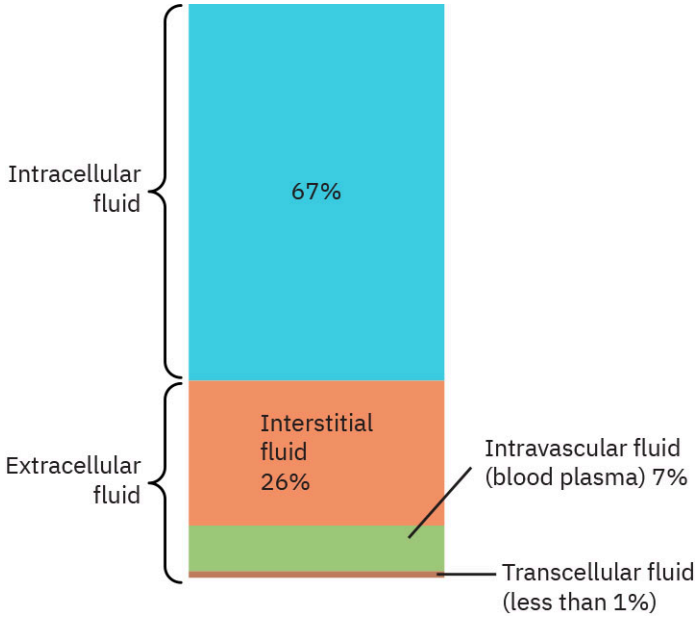

FIGURE 10.2 About two-thirds of body fluids are found within cells; the remaining fluids are extracellular. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Compartment	Definition	Characteristics
Intracellular fluid (ICF)	Fluid found inside cells	• ICF is composed of protein, water, electrolytes, and solutes. • ICF makes up approximately two-thirds of the body's total fluid volume. • The most abundant intracellular electrolyte is potassium.
Extracellular fluid (ECF)	Fluid found outside of cells Three subtypes: • Intravascular fluids, or plasma, are found in blood vessels. • Interstitial fluids surround cells. • Transcellular fluids include cerebrospinal, pericardial, synovial, intraocular, and pleural fluids.	• ECF makes up approximately one-third of the body's total fluid volume. • The most abundant extracellular electrolyte is sodium. • Intravascular solutes consist of red blood cells, white blood cells, and platelets. • Examples of interstitial fluid include lymph and edema.

TABLE 10.1 Characteristics of Body Fluids

Movement and Regulation of Body Fluid

The movement of body fluid between intra- and extracellular compartments is governed by several mechanisms, including oncotic pressure, hydrostatic pressure, and osmosis. The pressure created by colloid in a fluid is called **oncotic pressure** which prevents the movement of water from one solution to another. The force exerted by a fluid against a wall is called hydrostatic pressure. It results in the movement of fluid between compartments. For example, the hydrostatic pressure of blood is the pressure exerted by blood against the walls of the blood vessels by the heart's pumping action. The pressure exerted by plasma proteins, such as albumin and globulinis called **osmotic pressure**. It acts as a pulling force to keep fluids inside the vessel. Hydrostatic pressure opposes osmotic pressure at the arterial end of capillaries, where it pushes fluid and solutes out into the interstitial compartment. On the venous end of the capillary, hydrostatic pressure is reduced, which allows oncotic pressure to pull fluids and solutes back into the capillary. Figure 10.3 illustrates these opposing pressures inside a capillary.

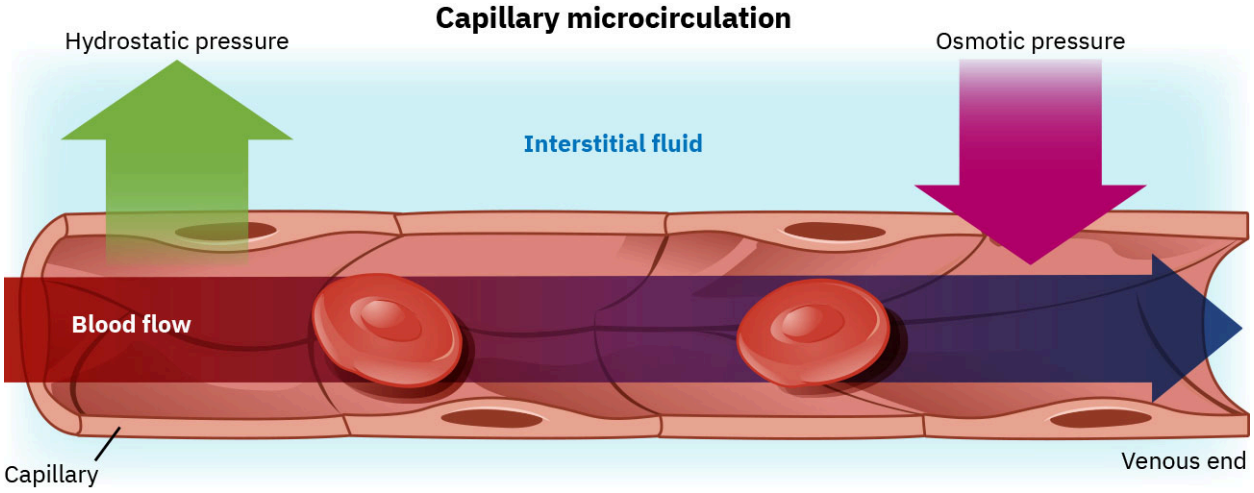

FIGURE 10.3 As blood flows through a capillary, the hydrostatic pressure inside the vessel opposes the osmotic pressure occurring in the interstitial fluid outside the vessel. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The movement of water through a semipermeable membrane is referred to as osmosis. The water moves from an

area of lesser solute concentration to an area of greater solute concentration, thereby equalizing the concentration of the solute on either side of the membrane. Figure 10.4 illustrates osmosis, in which water has moved to the right side of the membrane to equalize the concentration of solutes on that side with the left side. Being familiar with the concept of osmosis is especially important for understanding how the body maintains its balance of electrolytes.

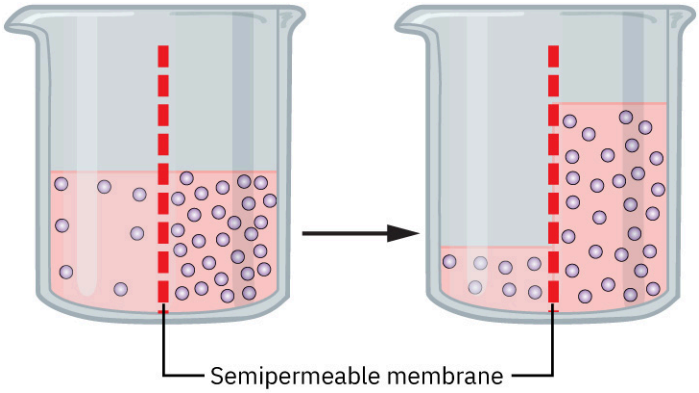

FIGURE 10.4 Through osmosis, water moves across a semipermeable membrane from an area of lesser concentration (left side of the membrane) to an area of great concentration (right side of the membrane). (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Routes of Gains and Losses

Fluids and electrolytes are gained and lost from the body through several **different routes** and mechanisms. Nearly all fluid and electrolyte gains occur through oral intake (e.g., eating and drinking). In a healthy adult, oral intake remains nearly equal to the body's output to maintain overall homeostasis. With some medical conditions, however, the intake or output of fluid becomes excessive, resulting in an imbalance and disruption to homeostasis. The various routes of fluid output (losses) are listed in Table 10.2.

Route	Mechanism
Urine output	• In a healthy adult, urine output should be approximately 1 mL/kg/h to maintain overall homeostasis. • At a minimum, urine output should be 30 mL/h.
Perspiration	• Daily amount lost will vary depending on factors such as temperature, activity level, and overall health. • Main solutes lost via this route are sodium, calcium, and potassium.
Respiratory losses	• A small amount (approximately 300 mL/d) of fluid is lost as water vapor during breathing. • This amount increases with hyperventilation and in certain climates and temperatures.
Gastrointestinal (GI) losses	• Most fluid in the GI tract is reabsorbed into the body, so these losses are minimal (approximately 250 mL/d). • GI losses increase with prolonged diarrhea or vomiting.

TABLE 10.2 Routes of Fluid Output

Evaluating Laboratory Values

Evaluating laboratory values is one of the most important nursing interventions for patients at risk for fluid and electrolyte imbalances. The nurse should be mindful of trends and changes in electrolyte levels that may indicate the patient is developing an imbalance that may threaten homeostasis. This chapter discusses specific characteristics, assessment findings, and treatments for common fluid and electrolyte imbalances in more detail.

Homeostatic Mechanisms

The body has many internal, or feedback, mechanisms in place that will attempt to compensate for fluid, electrolyte, and acid-base imbalances. These mechanisms are housed within major organs, including the kidneys, heart, and lungs, as well as within glands, including the pituitary and adrenal glands. Though these mechanisms are usually effective at compensating for imbalances, certain conditions may cause them to become insufficient and require medical intervention.

Kidney and Adrenal Functions

The kidneys play a major role in maintaining fluid, electrolyte, and acid-base balances. Most importantly, these organs filter the body's circulating fluids (5–6 liters in total) many times throughout the day, resulting in about 200 liters of daily fluid filtration. During this process, the kidneys actively remove excess toxins and other waste products for excretion as urine and promote the reabsorption of vital nutrients and electrolytes back into the bloodstream. In addition to filtering body fluid, the kidneys also actively maintain the body's pH within a tight range by excreting or retaining hydrogen ions as needed. Under normal circumstances, this mechanism will result in an adequate acid-base balance in the body, which is vital for most normal physiological processes to occur.

Hydrostatic pressure is especially important in governing the movement of water in the kidneys' nephrons to ensure proper blood filtering to form urine. As hydrostatic pressure in the kidneys increases, the amount of water leaving the capillaries also increases, and more urine filtrate is formed. If hydrostatic pressure in the kidneys drops too low, as can happen in dehydration, the functions of the kidneys will be impaired, and less wastes and fluid will be removed from the bloodstream. Any dysfunction or injury related to the kidneys can significantly affect the body's ability to maintain adequate overall fluid, electrolyte, and acid-base balances. For example, the presence of kidney stones can cause blockages that result in severe dysfunction of the kidney and resulting fluid and electrolyte imbalances. This highlights the significance of early intervention and appropriate treatment for conditions that negatively affect the kidneys' normal functions.

The adrenal glands, located on top of the kidneys, also play a major role in maintaining fluid and electrolyte balance. Specifically, these glands secrete aldosterone, a mineralocorticoid hormone that regulates water and sodium balance in the body. This hormone exerts its effects on the collecting ducts of the kidneys, where it promotes the retention of sodium and water in the bloodstream and increases the excretion of potassium as a waste product in the urine.

Renin-Angiotensin-Aldosterone System

When the kidneys detect low serum sodium levels or hypotension, they secrete a hormone called renin, which activates the renin-angiotensin-aldosterone system (RAAS) (Figure 10.5). This system is one of the most important compensatory mechanisms in the body, not only for fluid and electrolyte balance but also for the maintenance of adequate blood pressure and organ perfusion. The secreted renin acts on the inactive form of a peptide, known as angiotensinogen, released from the liver to create a hormone called angiotensin I. Angiotensin I is then transported to the lungs, where it interacts with angiotensin-converting enzyme (ACE) to synthesize angiotensin II, an active hormone that can exert its effects directly on blood vessels and the adrenal glands. When angiotensin II acts on blood vessels, it causes vasoconstriction, which increases blood pressure. When angiotensin II acts on the adrenal glands, it causes the release of aldosterone, which results in water and sodium retention and potassium excretion. Ultimately, the goals of the RAAS are to increase blood pressure, promote water and sodium retention, and excrete potassium. Thus, this compensatory mechanism plays a key role in maintaining the body's blood pressure, fluid and electrolyte balance, and overall homeostasis.

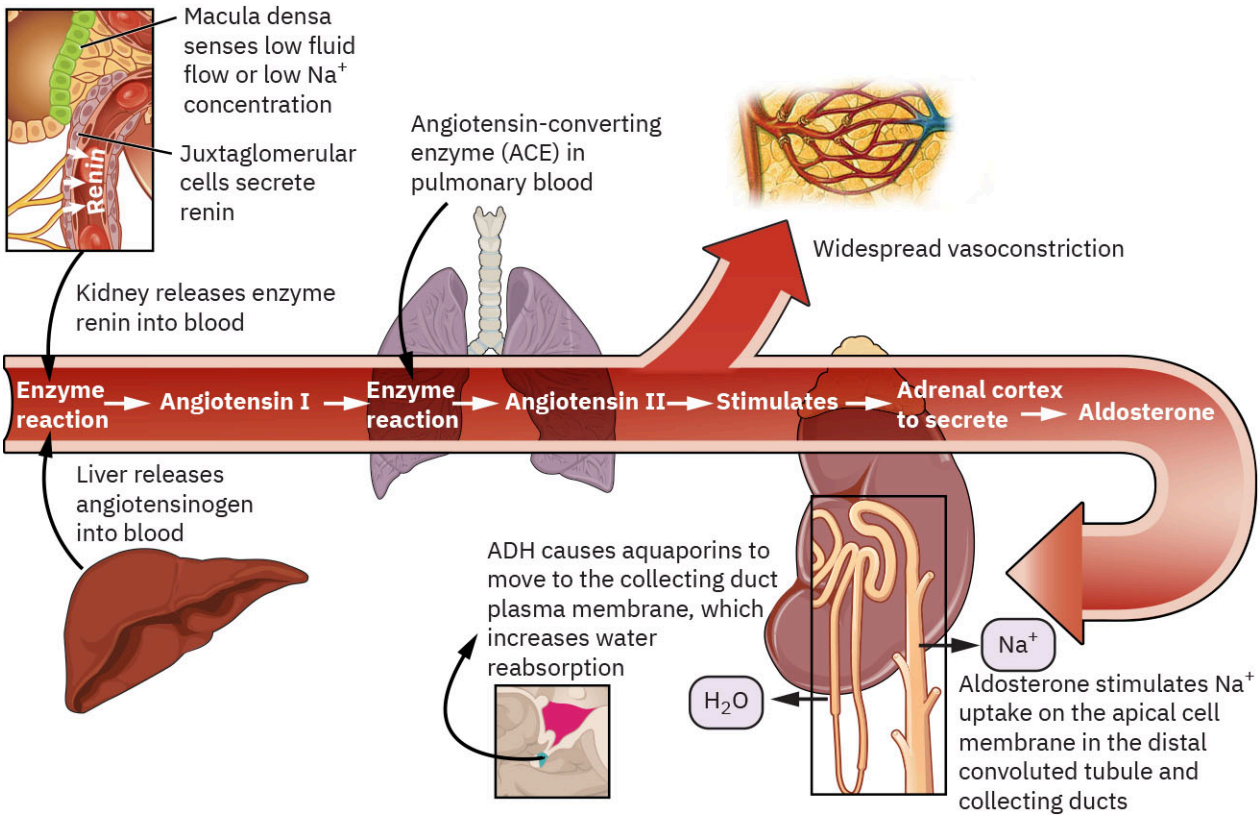

FIGURE 10.5 The renin-angiotensin-aldosterone system (RAAS) uses several important chemicals to increase blood pressure, promote water (H2O) and sodium (Na+) retention, and excrete potassium. ADH refers to antidiuretic hormone. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Natriuretic Peptides

Acting in direct opposition to the RAAS are natriuretic peptides (NPs). NPs are stored in the heart tissue and released when the body detects high blood pressure and fluid overload. The goals of NPs are to cause vasodilation of blood vessels, which decreases blood pressure, and causes sodium to be excreted as a waste product in the urine. These opposing hormones are part of the endocrine system's negative feedback loop, which allows the body to continuously maintain an appropriate balance of fluid and electrolytes, assuming the mechanisms are functioning optimally.

Cardiac and Lung Function

The heart and lungs are two other major organs that help the body maintain homeostasis. The heart is responsible for maintaining the systemic circulation of blood throughout the body, so any cardiac dysfunction can result in decreased tissue and organ perfusion. When decreased perfusion happens to the kidneys, the kidneys cannot effectively filter the blood, resulting in potentially serious fluid and electrolyte imbalances. The heart tissue also contains **baroreceptors**, specialized nerve cells that can detect the "stretch" (i.e., the level of vasoconstriction or dilation) of vessels, which reflects blood pressure. When these receptors detect a decrease in vasoconstriction (low blood pressure), the sympathetic nervous system is stimulated, resulting in increased heart rate and contractility to compensate for the low blood pressure. An example is seen in any shock state where blood vessels are dilated, causing hypotension, and the body responds with tachycardia in an effort to compensate.

The respiratory system plays a vital role in maintaining overall acid-base balance. While breathing in oxygen, the lungs will exhale carbon dioxide (CO_2). Within the body, CO_2, as a waste product of ventilation, becomes carbonic acid, which acts as an acid inside the body and so lowers blood pH. When the lungs are not functioning optimally, as seen with conditions such as chronic obstructive pulmonary disease (COPD) or an acute respiratory illness, CO_2 is retained in the body, resulting in excessive acid levels, or **acidosis**. On the other hand, in situations where hyperventilation occurs, the patient may be exhaling too much CO_2, causing buildup of excessive levels of bases in the body, known as **alkalosis**. See section 10.4 for more information about acid-base imbalances.

LIFE-STAGE CONTEXT

Age-Related Changes That Affect Homeostasis

As people age, they may experience a decrease in the function of many major organs, including the heart, kidneys, and lungs. This suboptimal organ function places older adults at higher risk for fluid, electrolyte, and acid-base imbalances. Specifically, a decrease in cardiovascular contractility due to aging may cause decreased organ perfusion. When the decreased blood volume reaches the kidneys, it may result in an impaired ability of the kidneys to filter the blood and excrete waste products. This predisposes older adult patients to fluid, electrolyte, and acid-base imbalances that threaten overall homeostasis. In a healthy adult, these imbalances may have mild symptoms, but they can quickly become life-threatening in older adults if left untreated.

Children, on the other hand, are especially susceptible to fluid imbalances, specifically dehydration. This is related to their small stature and low body mass, in combination with their increased metabolism.

Pituitary Function

Another important controlling mechanism for maintaining fluid balance is housed in the brain, through the pituitary gland. It is controlled by signals sent to the gland from the **hypothalamus**, a structure in the brain that acts as a control center for the endocrine system.

The solute concentration of the blood, or blood **osmolarity**, may change in response to the consumption of certain foods and fluids, as well as in response to disease, injury, medications, or other factors. Blood osmolarity is constantly monitored by **osmoreceptors**, which are specialized cells in the hypothalamus that are particularly sensitive to the concentration of sodium ions and other solutes. In response to high blood osmolarity, which can occur during dehydration or following a very salty meal, osmoreceptors signal the posterior pituitary to release antidiuretic hormone (ADH), also known as vasopressin, with the goal of restoring blood osmolarity to normal levels (275–295 mOsm/kg) by retaining water in the body. Antidiuretic hormone acts on the kidneys, causing them to hold onto more water in the blood vessels and excrete less fluid as urine. With more water retention, the concentration of solutes is reduced, resulting in normalized osmolarity and better maintenance of homeostasis. Figure 10.6 illustrates the communication between the hypothalamus and pituitary gland that results in the release of ADH.

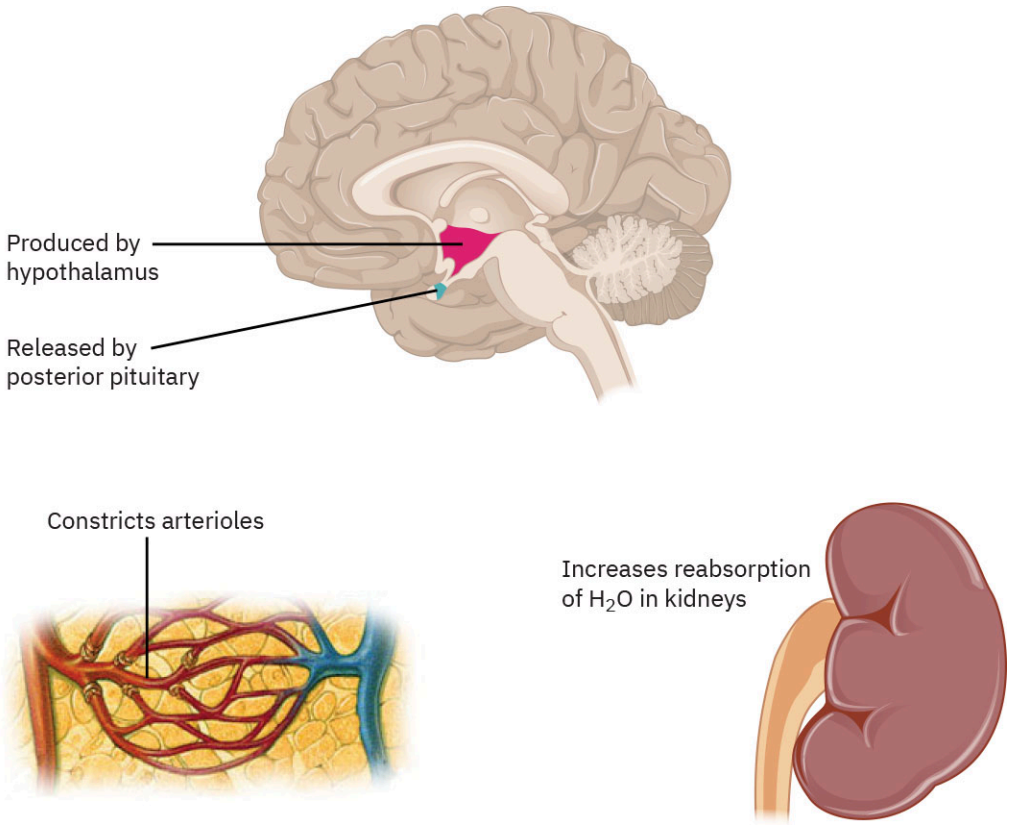

FIGURE 10.6 Antidiuretic hormone (ADH) is produced in the hypothalamus and released by the posterior pituitary gland. It causes the kidneys to retain water (H2O) and constricts arterioles in the peripheral circulation. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

10.2 Fluid Disturbances and Replacement

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology and clinical manifestations of hypovolemia and hypervolemia
- Describe the diagnostics and laboratory values related to hypovolemia and hypervolemia
- Apply nursing concepts to and plan associated nursing care for patients with hypovolemia and hypervolemia
- Evaluate the efficacy of nursing care for patients with hypovolemia and hypervolemia
- Describe the medical therapies that apply to the care of those experiencing hypovolemia and hypervolemia
- Identify the appropriate fluid replacement method for various fluid disturbances

The importance of maintaining a normal fluid balance within the body cannot be overstated. Both excessive and inadequate amounts of fluid can alter the body's homeostasis and become life-threatening if left untreated. These imbalances are common in many different medical conditions, which nurses must be able to effectively monitor and actively treat to restore overall fluid balance and homeostasis.

Hypovolemia

A decrease in fluid volume in the intravascular space, known as **hypovolemia**, occurs when fluid loss is greater than fluid intake, resulting in a deficient volume of fluid in the body. Dehydration, often misconstrued for hypovolemia, is a decrease in extracellular fluid that can cause hypovolemia. Hypovolemia may occur on its own, affecting only the body's overall fluid balance, or in combination with other imbalances, such as those involving electrolytes or acids and bases.

Pathophysiology of Hypovolemia

The underlying pathophysiology of hypovolemia involves mechanisms that increase fluid loss from the body and

often are coupled with limited fluid intake needed to replenish lost fluids. Common causes of hypovolemia include

- burns
- excessive diaphoresis
- excessive urine loss (from diabetes insipidus or diabetes mellitus)
- fever
- malnutrition
- poor oral fluid intake
- prolonged diarrhea or vomiting
- severe hemorrhage

Certain risk factors may predispose some individuals to experiencing hypovolemia. These risk factors include

- chronic disease (e.g., diabetes mellitus, kidney disease)
- exercising or working outdoors in hot weather
- old age
- using diuretic medication
- young age (e.g., infants, children)

Assessment and Diagnostics of Hypovolemia

Hypovolemia can develop quickly and become life-threatening if not assessed and treated swiftly. Nurses can perform several important assessments to determine the patient's overall fluid status and confirm the presence of hypovolemia. These assessments and their expected findings are described in Table 10.3.

Assessment	Findings Associated with Hypovolemia
Physical assessment	• Confusion • Decreased level of consciousness • Dizziness • Dry skin and mucous membranes • Excessive thirst • Flat neck veins • Headache • Increased capillary refill time • Lethargy • Muscle cramps • Poor skin turgor (Figure 10.7) • Tachycardia
Intake and output	• Dark, concentrated urine • Decreased oral fluid intake • Oliguria
Daily weights	• Weight loss (>3% over seven days indicates potential dehydration)

TABLE 10.3 Assessments and Findings Associated with Hypovolemia

Assessment	Findings Associated with Hypovolemia
Vital signs	• Fever • Hypotension • Tachycardia • Tachypnea
Laboratory values	• ↑ Hemoglobin and hematocrit • ↑ Serum creatinine and blood urea nitrogen levels • ↑ Serum osmolarity • ↑ Serum sodium levels (hypernatremia) • ↑ Urine specific gravity

TABLE 10.3 Assessments and Findings Associated with Hypovolemia

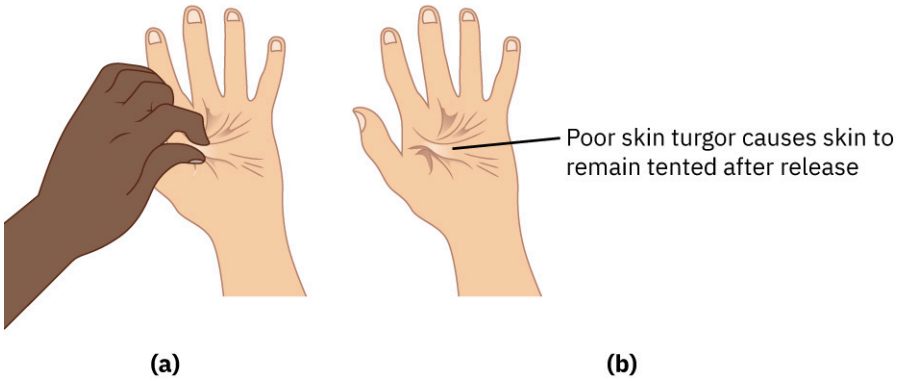

FIGURE 10.7 To test skin turgor, (a) pinch the skin and observe whether it returns to its original state. (b) Skin with poor turgor remains tented after being pinched, indicating a fluid-volume deficit. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

There are no diagnostic tests specifically for hypovolemia. This diagnosis is based on clinical manifestations, assessment findings, trends in laboratory values, and the patient's physiological response to treatment with fluid resuscitation, which is described in more detail in the following sections.

Nursing Care of Patients with Hypovolemia

First and foremost, effective nursing care for patients with hypovolemia begins with early detection of the condition. The nurse should be mindful of subtle changes in assessment findings or laboratory value trends that may indicate the development or worsening of a fluid deficit. Once the diagnosis has been made, the main goals of nursing care include restoring fluid balance to an optimal level, maintaining homeostasis, and preventing the development of complications such as **hypovolemic shock**, a life-threatening condition in which the heart cannot get enough blood and oxygen to tissues and organs.

Recognizing and Analyzing Cues

Because of the body's internal compensatory mechanisms, patients with hypovolemia may be asymptomatic at first. This highlights the importance of assessing for subtle changes in condition that may indicate the early development of a fluid deficit. Some of these early signs include

- confusion due to decreased perfusion to the brain
- hypotension, because the lack of fluid results in lower-than-normal blood pressure within blood vessels
- thirst, including dry mucous membranes

Prioritizing Hypotheses, Generating Solutions, and Taking Action

If the nurse observes signs and symptoms that are indicative of a fluid deficit, one of the first actions they should take is to gather more information and assessment data. If they have not been done already, the nurse should begin to measure and document the patient's intake and output to monitor for a steadily decreasing urine output, another potential early clinical manifestation of hypovolemia. Daily weights should be ordered to measure and monitor

overall fluid balance. If possible, the nurse should also obtain laboratory values such as serum creatinine, blood urea nitrogen (BUN), and urine specific gravity, because these tests can provide more information about the patient's overall fluid status and condition. Additionally, it is important for the nurse to take proactive actions to prevent the worsening of the condition. For example, if the patient's fluid loss stems from excessive vomiting, the nurse should ensure the patient has appropriate antiemetic medications available to prevent further fluid loss and keep the patient's condition from deteriorating. Fluid replenishment should be initiated intravenously if the patient cannot tolerate oral intake.

Evaluation of Nursing Care for Patients with Hypovolemia

After diagnosing and initiating treatment for hypovolemia, the nurse should evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary.

After treatment, the nurse should monitor the patient for signs indicating that the patient's fluid imbalance has been corrected. Signs that would indicate an improvement in condition include

- adequate blood pressure (specifically, a systolic blood pressure >100 mm Hg)
- clear, lighter-colored urine
- decreased confusion
- improved level of consciousness
- improved urine output (at minimum, 30 mL/h)
- moist mucous membranes
- normal capillary refill time and improved skin turgor
- normalized laboratory values (e.g., BUN, creatinine)
- vital signs within normal ranges

Medical Therapies and Related Care

The main aspect of medical treatment for a fluid deficit involves the replacement of lost fluid back into the body. Sometimes it is enough to encourage the patient to consume more fluids orally, especially water. However, in more severe cases, medical treatment with intravenous (IV) fluid therapy may be necessary.

The purpose of IV therapy for treating hypovolemia is to replace fluids to replenish blood volume. Using a peripheral IV catheter or central line, IV fluids are injected via a vein directly into the patient's bloodstream, where they act rapidly in the body to restore fluid volume. This treatment allows large amounts of fluids to be administered quickly to restore significant fluid volume losses, such as those experienced with severe hemorrhage and trauma. Once the fluid enters the vein, there is no way to terminate the action. Therefore, it is important to properly prepare the IV fluid, correctly calculate the dose and rate, and administer it safely to the patient. It is important to note that IV fluid administration is considered a medical intervention and requires an order from the provider prior to the initiation of therapy.

Types of IV Solutions for Therapy

Intravenous fluid therapy is administered to restore fluid volume in the intravascular compartment or within the blood vessels. However, IV fluids can also be used to facilitate the movement of fluid between compartments. The three types of IV fluids are isotonic, hypotonic, and hypertonic, and they vary on the basis of their **tonicity**, or composition and concentration of dissolved particles. An **isotonic** solution contains the same number of dissolved solutes compared with blood. A **hypotonic** solution contains fewer dissolved solutes than blood contains. A **hypertonic** solution contains more dissolved solutes than blood contains. Table 10.4 describes characteristics of each category of IV fluid. Figure 10.8 illustrates the osmotic effects of each type of fluid on red blood cells.

Characteristic	Isotonic Fluid	Hypotonic Fluid	Hypertonic Fluid
Tonicity	Contains the same number of solutes compared with blood	Contains fewer solutes than blood contains	Contains more solutes than blood contains
Fluid movement	No net movement of fluid	Fluid moves into cells (can cause cellular swelling)	Fluid moves out of cells (can cause cellular shrinking)
Situations used	Fluid replacement in states such as: • Acute blood loss • Burns • Dehydration from excessive vomiting or diarrhea • Diabetic ketoacidosis • Shock	• Hypovolemia in combination with hypernatremia • The goal is to restore lost fluid volume but not increase sodium levels.	• Hypovolemia in combination with hyponatremia • The goal is to restore lost fluid volume as well as lost sodium.
Nursing considerations	• Monitor for signs of fluid overload • Monitor for diluted electrolytes • Use with caution in patients at risk of fluid overload (e.g., those with congestive heart failure, kidney failure)	• Monitor for hypovolemia, hypotension, and confusion as fluid shifts out of the intravascular space. • Administer slowly and cautiously to prevent cardiovascular collapse and increased intracranial pressure from cerebral edema.	• Monitor for signs of fluid overload or hypernatremia. • Contraindicated in patients with renal failure • May be irritating to smaller veins • Administer slowly and cautiously to prevent pulmonary edema.
Examples	• 0.9% normal saline • Lactated Ringer's solution	• 0.45% normal saline	• 3% normal saline • 5% normal saline

TABLE 10.4 Types of IV Fluids

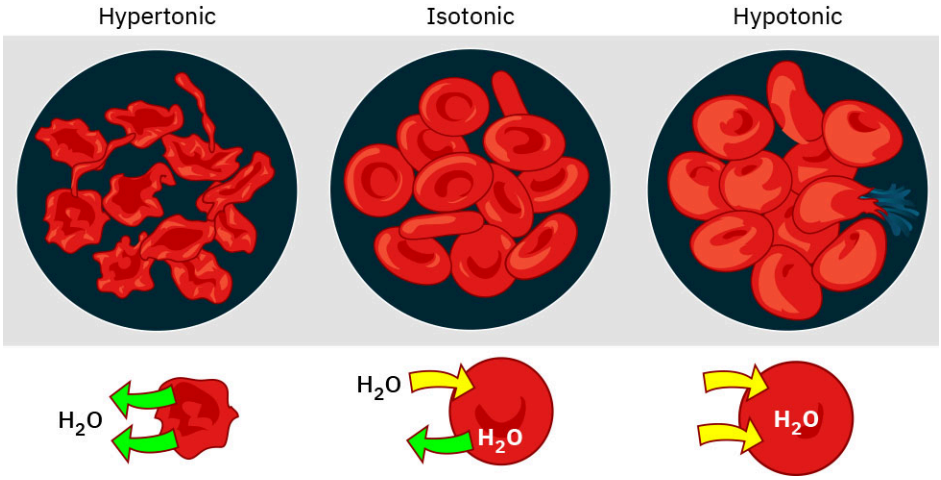

FIGURE 10.8 Hypertonic fluids cause water (H2O) to flow out of cells, hypotonic fluids cause water to flow into cells, and isotonic fluids cause no net change in osmosis. CLINICAL SAFETY AND PROCEDURES (QSEN)

Safe Administration of IV Fluid Therapy

When initiating or changing a bag of IV fluids or medications, it is important to remember the following points:

- IV fluids are a medication. Verify the provider's orders and check that the patient does not have an allergy to the medication. Perform the six rights of medication administration three times, as you would when giving any other medication. Check the type of fluid and the expiration date, and verify the fluid is free of discoloration and sediment. Check the expiration date when obtaining a new tubing administration set.
- Examine the bag to ensure it is intact and not leaking. There may be moisture on the inside of the plastic IV bag storage container; this is normal.
- Verify the infusion rate of IV fluids is appropriate based on the patient's age, size, preexisting medical conditions, and prescribed indication. If a manual calculation is needed to set the IV flow rate, calculate the rate, then double-check the calculated rate with another registered nurse.
- IV tubing administration sets require routine replacement to prevent infection. Follow agency policy regarding initiating tubing change before initiating a new bag of fluid or medication.
- If administration-set tubing is present, trace the tubing from the patient to its point of origin to make sure you are accessing the correct port.
- Assess the IV site. Inspect for redness, swelling, or tenderness that could be a sign of irritation, inflammation, or infection.
- Ensure the IV site is patent when initiating new fluid or medication. Aspirate for blood return and flush the IV catheter according to agency policy.

Hypervolemia

Fluid volume overload, known as **hypervolemia**, occurs when an increased amount of fluid is retained in the intravascular compartment, resulting in an excess fluid volume. This condition may occur on its own, affecting overall fluid balance, or in combination with other imbalances, such as those involving electrolytes or acids and bases.

Pathophysiology of Hypervolemia

The underlying pathophysiology of hypervolemia involves mechanisms that increase fluid retention in the body. Common causes of hypervolemia include

- excessive consumption of fluids or salts
- heart failure
- kidney failure

- liver cirrhosis

Clinical Manifestations

Hypervolemia can quickly become life-threatening if not detected and treated early. Common clinical manifestations of hypovolemia include

- **ascites**, or fluid retention in the abdominal cavity
- bounding pulses
- crackles in the lungs
- jugular venous distension (JVD)
- pitting **edema**, or swelling, in dependent tissues and extremities due to fluid accumulation in the interstitial space (Figure 10.9 and Table 10.5)
- Weight gain

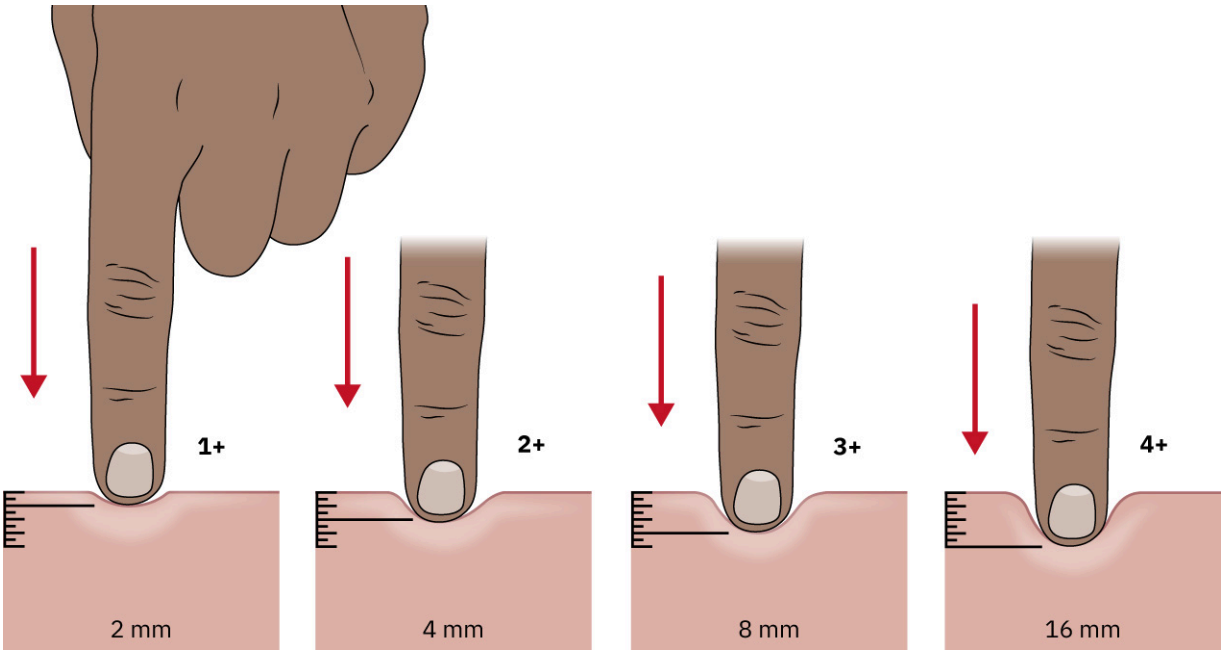

FIGURE 10.9 If a person has pitting edema, pressing on their skin leaves depressions, or "pits." (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Assessment and Diagnostics

There are several key assessments that nurses can perform to determine the patient's overall fluid status and confirm the presence of hypervolemia. These assessments and their expected findings are described in Table 10.5.

Assessment	Findings Associated with Hypervolemia
Physical assessment	• Abdominal distention, diagnosed ascites • Altered mental status or confusion • Bounding pulses • Cough • Crackles in the lungs • Dyspnea • Headache • JVD • Pitting edema (especially in the lower extremities) • Seizures
Intake and output	• Polyuria
Daily weights	• Weight gain
Vital signs	• Hypertension
Laboratory values	• ↓ BUN • ↓ Hemoglobin and hematocrit • ↓ Serum sodium levels (hyponatremia) and osmolality related to dilution

TABLE 10.5 Assessments and Findings Associated with Hypervolemia

A useful test used for diagnosing hypervolemia is a chest X-ray, because it may visualize fluid congestion in the lungs. However, there are no specific diagnostic tests for hypervolemia. As with hypovolemia, the diagnosis is made on the basis of clinical manifestations and assessment findings, laboratory value trends, and the patient's physiological response to treatment.

Nursing Care of the Patient with Hypervolemia

Effective nursing care for patients with excess fluid volume begins with early detection of the imbalance. The nurse should monitor for subtle changes in condition that may indicate the development or worsening of fluid overload. Once the diagnosis has been made, the main goals of nursing care include removing excess fluid, maintaining homeostasis, and preventing the development of complications such as **pulmonary edema**, a life-threatening condition in which the respiratory system no longer functions effectively due to excessive fluid accumulation in the lungs.

REAL RN STORIES

Name: Jenny, RN
Years in Practice: Less than one
Clinical Setting: Medical-surgical unit
Geographic Location: Midwest

Jenny, a new graduate registered nurse, is taking care of Mrs. Smith, a 56-year-old female patient on the medical-surgical unit. Mrs. Smith just arrived on the unit after a hip replacement surgery and the physician's orders are that the currently running IV liter of normal saline should be completed before placing a saline lock. After getting Mrs. Smith settled on the unit, Jenny leaves for about 2 hours to check on her other patients. When she comes back and assesses Mrs. Smith, she hears significant crackles in Mrs. Smith's lungs. She consults the electronic health record and realizes that Mrs. Smith has a history of congestive heart failure, leaving her at increased risk for hypervolemia.

Jenny quickly contacts the on-call physician who orders a STAT dose of IV furosemide and supplemental oxygen. After administration of the oxygen and diuretic, the patient reports being able to breathe much easier and her crackles are significantly improved.

Recognizing and Analyzing Cues

In the early stages of hypervolemia, the body is usually able to compensate for the increased fluid volume. Eventually, however, the major organs involved in fluid filtration and excretion become tired, resulting in fluid excess. Some of the earliest signs of hypervolemia the nurse should monitor for include

- confusion or headache, due to increased perfusion to the brain
- edema in the extremities, which occurs as fluid leaks from intravascular space into the interstitial tissues
- polyuria, as the body attempts to compensate for excessive fluid by excreting more as urine

Prioritizing Hypotheses, Generating Solutions, and Taking Action

If the nurse observes signs symptoms are indicative of hypervolemia, more information and data should be gathered to aid in the diagnosis. Similar to hypovolemia, it is important that the nurse begin accurately measuring and documenting intake and output. In some cases, one of the first signs of fluid excess is a steadily increasing urine output as the body attempts to compensate and remove excess fluid. It is also important for the nurse to take proactive actions to prevent worsening of the condition. For example, if the patient is experiencing severe pitting edema, the nurse should implement measures such as elevating the affected extremity above heart level or applying compression stockings to lessen the amount of edema present. Daily weights are another measurement intervention to enable accurate fluid balance and monitoring.

Evaluation of Nursing Care for Patients with Hypervolemia

After diagnosis of and initiation of treatment for hypervolemia, it is important for the nurse to evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary.

After treatment, the nurse should monitor the patient for signs indicating their fluid imbalance has been corrected. Signs that would indicate an improvement in condition include

- decreased confusion
- improved edema or ascites
- normal hourly urine output (approximately 30 mL/h)
- normalized laboratory values (e.g., BUN, hemoglobin)
- pulse oximetry greater than 92% and normal lung sounds
- vital signs within normal ranges

Medical Therapies and Related Care

If the fluid overload is occurring secondary to IV fluid therapy, simply stopping the fluid infusion and initiating a fluid restriction may be adequate to restore normal fluid balance. In more severe cases of hypervolemia, however, the use of diuretic medications or invasive procedures such as dialysis may be necessary. Potential treatment options for hypervolemia are displayed in Table 10.6.

Treatment	Rationale	Nursing Considerations
Fluid and sodium restriction	• Limiting oral intake of fluid and sodium can help decrease fluid volume in the body.	• Specific allowed daily amounts are determined on the basis of the patient's degree of overload and other factors, such as body weight.
Pharmacologic therapy: diuretics	Indicated for excess fluid removal: • Oral diuretics are indicated for less severe conditions. • IV diuretics are indicated for more severe conditions that require faster fluid removal (e.g., pulmonary edema).	• Monitor patient closely for electrolyte imbalances. • Monitor for increase in urine output. • Monitor lung functioning.
Dialysis	• Indicated for life-threatening cases of hypervolemia that require emergent fluid removal.	• Monitor patient closely for electrolyte imbalances or hypovolemia that may occur during or directly after dialysis.

TABLE 10.6 Treatments for Hypervolemia

10.3 Electrolyte Imbalance

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology and clinical manifestations of various electrolyte imbalances
- Describe the diagnostics and laboratory values related to various electrolyte imbalances
- Apply nursing concepts and plan associated nursing care for patients with various electrolyte imbalances
- Evaluate the efficacy of nursing care for patients with various electrolyte imbalances
- Describe the medical therapies that apply to the care of those experiencing electrolyte imbalances

Ions dissolved in body fluid are known as **electrolytes**. They play an important role in most physiological functions and assist in maintaining homeostasis. There is a very narrow target range for normal electrolyte values, and even slight abnormalities can have devastating consequences. For this reason, it is crucial to understand normal ranges for the body's key electrolytes: potassium, sodium, calcium, magnesium, phosphorus, and chloride. Nurses should also understand the causes and clinical manifestations of electrolyte imbalances and appropriate medical and nursing interventions.

LINK TO LEARNING

Explore additional information on normal laboratory values (https://openstax.org/r/77normlabvalues) and view a helpful cheat sheet.

Potassium Overview

Potassium is the most abundant electrolyte in the intracellular fluid compartment and is exchanged with sodium back and forth into and out of the cell by the sodium-potassium pump mechanism. Potassium levels normally range from 3.5 to 5.1 mEq/L, with slight range variations between different health care institutions depending on their policies and laboratory equipment. Potassium is obtained through the dietary consumption of foods such as bananas, oranges, and tomatoes, and its excretion is regulated by aldosterone in the kidneys. Recall that aldosterone causes sodium reabsorption and potassium excretion in the distal tubule of the kidneys. In response to potassium levels rising or sodium levels falling in the bloodstream, the adrenal cortex releases aldosterone and targets the kidneys. In response, the kidneys excrete potassium and reabsorb sodium. Potassium is also affected by

insulin, which moves potassium back into the cells from the extracellular fluid compartment.

Potassium Imbalances

Potassium is necessary for normal cardiac function, neural function, and muscle contractility, including effective contractility of the cardiac muscles. In a potassium imbalance, there is either too much potassium present in the blood (hyperkalemia) or too little (hypokalemia). Both types require early assessment and intervention to prevent severe adverse effects, including cardiac dysrhythmias or arrest.

A decreased potassium level in the blood is known as **hypokalemia**. Common causes of hypokalemia include

- excessive vomiting or diarrhea
- use of potassium-wasting diuretics or insulin use
- decreased dietary intake of potassium

An increased potassium level in the blood is known as **hyperkalemia**. Common causes of hyperkalemia include

- administration of potassium-sparing diuretics or oral potassium supplements
- kidney failure
- metabolic acidosis

Table 10.7 compares the pathophysiology and clinical manifestations of, and diagnostic tests, and treatments for both types of potassium imbalances.

	Hypokalemia	Hyperkalemia
Pathophysiology	Increased excretion of potassium (e.g., due to prolonged vomiting or diarrhea, potassium-wasting diuretics) or abnormal movement of potassium into cells from the intravascular space (e.g., resulting from insulin administration)	Decreased renal excretion of potassium (e.g., kidney failure) or abnormal movement of potassium out of cells and into intravascular space (e.g., acidosis, potassium-sparing diuretics)
Clinical manifestations	• Anorexia, nausea, or vomiting • Cardiac dysrhythmias (peaked T waves and prolonged QRS complex) • Constipation • Dizziness • Fatigue • Hypoactive reflexes • Hypotension • Muscle weakness or cramps • Paresthesia • Polyuria	• Cardiac dysrhythmias (depressed T waves, and & bradycardia) • Flaccid paralysis • Irritability • Muscle weakness or cramps • Tachycardia

TABLE 10.7 Hypokalemia and Hyperkalemia

	Hypokalemia	Hyperkalemia
Diagnostic tests	• Electrocardiogram will show depressed T waves, prolonged PR interval, and absent P waves (Figure 10.10) • Serum potassium level (<3.5 mEq/L)	• Electrocardiogram will show peaked T waves, ST segment depression, or appearance of U waves (Figure 10.10) • Serum potassium level (>5.1 mEq/L)
Treatments	• Increased dietary intake of potassium or oral potassium supplements • IV potassium replacement for more severe cases • Treat underlying cause	• Administration of IV insulin to promote cellular uptake of potassium • Dietary potassium restriction • Hemodialysis for severe, refractory cases • Loop diuretic administration (e.g., furosemide [Lasix]) to promote potassium excretion in the urine • Sodium polystyrene sulfonate (Kayexalate), sodium-zirconium cyclosilicate (Lokelma), or patiromer (Veltassa) administration (oral or enema) to promote potassium excretion in the stool • Treat underlying cause

TABLE 10.7 Hypokalemia and Hyperkalemia

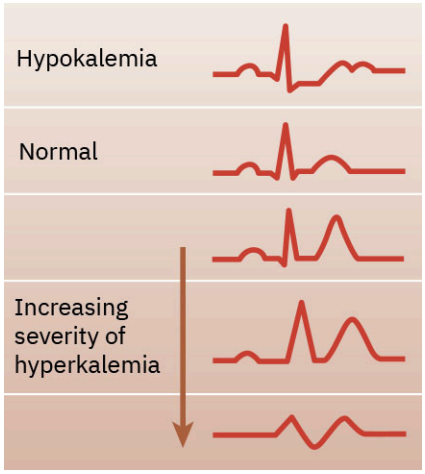

FIGURE 10.10 As potassium levels increase, the electrocardiogram shows a widening PR interval, longer QRS duration, and peaked T waves. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Nursing Care of Patients with Hypokalemia

Nursing care for patients with hypokalemia should focus on monitoring the patient's condition and preventing associated complications, especially the development of deadly cardiac dysrhythmias.

Recognizing Cues and Analyzing Cues

In the early stages of hypokalemia, the patient may be asymptomatic. However, when potassium values are less than 3.0 mEq/L, signs and symptoms become more obvious and can develop and progress quickly. It is important that the nurse monitor the patient for signs and symptoms that would indicate the hypokalemia is not improving.

Clinical manifestations associated with hypokalemia that should be assessed are listed in Table 10.7.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

First and foremost, because potassium imbalances can result in lethal cardiac dysrhythmias, it is imperative that the nurse ensure the patient's cardiovascular function is being closely monitored. Patients with hypokalemia should be placed on continuous telemetry monitoring for the early detection of electrocardiogram (ECG) changes that may indicate the development of abnormal rhythms. If the patient is being treated with oral potassium supplements, the nurse should encourage the patient to consume a large glass of water with the medication to help facilitate absorption and prevent gastrointestinal (GI) upset. If the patient has a more severe case of hypokalemia that requires administration of potassium intravenously, the nurse should be aware of the following additional safety concerns:

- Because too much potassium (especially when administered too quickly) can cause life-threatening cardiac dysrhythmias, it should never be administered as an IV push medication. Instead, IV potassium should always be given slowly over several hours via an IV pump.
- Intravenous administration of potassium can be irritating to the veins, so the patient may require co-administration of fluids to dilute the potassium or the placement of a central line in a bigger vein.

Evaluation of Nursing Care of the Patient with Hypokalemia

After diagnosis of and initiation of treatment for hypokalemia, it is important for the nurse to evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment, the nurse should monitor the patient for signs indicating the potassium imbalance has been corrected. Signs that would indicate an improvement in condition include

- constipation
- improved muscle weakness, cramps, and paresthesia
- normal bowel movement(s)
- normal ECG findings
- normal reflexes
- normalized serum potassium level (3.5–5.1 mEq/L)

Nursing Care of Patients with Hyperkalemia

Nursing care for patients with hyperkalemia is like that of those with hypokalemia in that care should focus on monitoring the patient's condition and preventing associated complications, especially the development of lethal cardiac dysrhythmias.

Recognizing and Analyzing Cues

Though patients with hyperkalemia may be asymptomatic initially, because of internal compensatory mechanisms, clinical manifestations can develop quickly as potassium levels increase. A serum potassium level of greater than 6.0 mEq/L warrants prompt intervention and appropriate treatment to prevent serious complications.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Just as with hypokalemia, one of the most important nursing interventions is to closely monitor the patient's cardiovascular function, typically with the use of continuous telemetry monitoring. If the patient is being treated with medications such as sodium polystyrene sulfonate (Kayexalate), it is important for the nurse to monitor the patient's bowel movements. These kinds of medications promote the excretion of potassium in the stool, so the patient will likely have multiple loose stools soon after the medication is administered. If so, the nurse should monitor the patient closely for skin breakdown and ensure they are clean and dry between bowel movements to promote an optimal level of skin integrity.

If the patient is receiving therapy with IV diuretics, it is important for the nurse to monitor the patient's serum electrolyte levels closely. Occasionally, diuretics may result in the loss of too many electrolytes and can cause hypokalemia. For this reason, it is often necessary to provide potassium supplements when administering loop and thiazide diuretics, because potassium is excreted from the kidneys along with water. People taking diuretics will urinate more frequently, so the nurse should ensure the patient can ambulate safely to the bathroom on their own or that they have a call light within reach so they can call for assistance to prevent falls.

Evaluation of Nursing Care of the Patient with Hyperkalemia

After diagnosis of and initiation of treatment for hyperkalemia, it is important that the nurse evaluates patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment, the nurse should monitor the patient for signs indicating the potassium imbalance has been corrected. Signs that would indicate an improvement in condition include

- improved muscle weakness, cramps, and paresthesia
- normal ECG findings
- normal reflexes
- normalized serum potassium level (3.5–5.1 mEq/ L)

REAL RN STORIES

Nurse: Jamie, RN
Years in Practice: Less than one
Clinical Setting: Medical-surgical unit
Geographic Location: South

Jamie, a new graduate nurse on the general medical-surgical unit, was working one of her first night shifts on her own, without a preceptor, when she was informed that she would be taking a patient from the emergency department (ED) who presented with confusion. The ED nurse called Jamie to give report and described the patient as "an older adult who came from a local nursing home and is confused. It's probably a urinary tract infection, but we are waiting on results from the urine sample. I will bring her up to you in a few minutes."

Once the patient arrived in the room, Jamie started her assessment. She spoke softly and gently to the older patient, who was clearly scared and anxious. When the patient said, "My heart is skipping around in my chest," Jamie determined she was also experiencing cardiac issues. On the basis of this information, Jamie placed the patient on telemetry monitoring and noticed tall, peaked T waves. She immediately called the resident physician and got an order to collect a blood sample to check the patient's blood cell count and to have laboratory tests conducted, including an electrolyte panel. The patient's potassium level came back at 6.1 mEq/L. Jamie made another phone call to the physician and requested an order for Kayexalate. The patient's potassium level was quickly restored to a normal level, preventing any further complications. The patient stabilized and was able to leave the hospital 2 days later.

Sodium Overview

Sodium is the most abundant electrolyte in the extracellular fluid compartment. Sodium levels in the blood typically range from 136 to 145 mEq/L, depending on the health care institution's normal reference range, and sodium levels are maintained by the sodium-potassium pump mechanism. Sodium plays an important role in maintaining adequate fluid balance in the intravascular and interstitial spaces; it also contributes to normal nerve and muscle function.

Recall from previous sections that sodium is regulated by the RAAS in the kidneys as well as by the release of ADH by the pituitary gland. Additionally, it is important to remember that wherever sodium travels, water follows.

Sodium Imbalances

In sodium imbalances, there is either too much sodium present in the blood (hypernatremia) or too little (hyponatremia). Both types are common and require early assessment and intervention to prevent severe adverse effects.

A decreased sodium level in the blood is known as **hyponatremia**. Hyponatremia can be caused by excess water intake or excessive administration of hypotonic IV solutions. For example, a marathon runner who rehydrates only with water rather than fluids containing solutes, like sports drinks, can develop hyponatremia due to dilution. Altered sodium levels often cause neurological signs and symptoms due to the movement of water into brain cells, which causes them to swell.

An elevated sodium level in the blood is known as **hypernatremia**. Typically, hypernatremia is caused by excess water loss due to lack of fluid intake, vomiting, or diarrhea. Elevated sodium levels in the blood cause the osmotic movement of water out of the cells to dilute the blood. This causes the body's cells to shrink, which is referred to as cellular dehydration. This fluid shift can have a significant impact on various organs of the body and, as with hyponatremia, is especially notable in the patient's neurological function.

Table 10.8 compares the pathophysiology and clinical manifestations of, and diagnostic tests and treatments for both types of sodium imbalances.

	Hyponatremia	Hypernatremia
Pathophysiology	Increased excretion of sodium (e.g., due to prolonged vomiting or diarrhea, diuretics) or dilution of sodium (e.g., due to increased water intake without electrolyte replenishment; overuse of hypotonic fluid replacement)	Excessive sodium intake (e.g., a high-sodium diet) or decreased fluid volume (e.g., due to prolonged vomiting or diarrhea; hypovolemia)
Clinical manifestations	• Abdominal cramps • Coma • Confusion • Headache • Nausea/vomiting • Seizures	• Confusion • Irritability • Lethargy • Seizures • Thirst
Diagnostic tests	• Serum sodium level (<136 mEq/L)	• Serum sodium level (>145 mEq/L)
Treatments	• Discontinue hypotonic IV fluid administration • Hypertonic IV fluid administration for severe cases • Limit oral water intake • Treat underlying cause	• Decrease dietary intake of sodium • Increase oral water intake • Rehydration with hypotonic IV fluids • Treat underlying cause

TABLE 10.8 Hyponatremia and Hypernatremia

Nursing Care of Patients with Hyponatremia

Nursing care for patients with hyponatremia should be focused on monitoring the patient's condition and preventing associated complications, especially the development of neurological complications.

Recognizing and Analyzing Cues

In the early stages of hyponatremia, the patient may be asymptomatic. However, as sodium levels continue to fall, signs and symptoms can begin quite suddenly and cause adverse neurological effects. With more acute declines in sodium levels—typically when the level drops to about 115 mEq/L—symptoms occur quickly and are more severe. Clinical manifestations associated with hyponatremia that should be assessed are listed in Table 10.8. Remember, where sodium goes, water follows. In cases of hyponatremia, the sodium level inside the vessel is low, indicating that the sodium has moved elsewhere, often the brain tissue. If that is the case, water will follow the sodium to the brain, resulting in signs and symptoms such as confusion and decreased level of consciousness.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

For patients who can eat and drink, nurses should promote the intake of sodium through salty food and drink options such as broth salt tablets or sports drinks. For patients unable to eat or drink, the main treatment is IV sodium replacement. This is typically done by administering isotonic fluids such as normal saline or lactated Ringer's, because both contain sodium. If the nurse is administering IV fluids with a goal of correcting sodium

balance, it is important to avoid giving the fluids too quickly. If sodium levels increase too fast (>0.5 mEq/L/h), severe neurologic damage may occur due to the movement of fluid out of brain cells, resulting in cellular shrinkage. This condition is called **osmotic demyelination syndrome**.

Evaluation of Nursing Care for Patients with Hyponatremia

After diagnosis of and initiation of treatment for hyponatremia, it is important that the nurse evaluates patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment, the nurse should monitor the patient for signs indicating that the sodium imbalance has been corrected. Signs that would indicate an improvement in condition include

- improved mentation and level of consciousness
- normal reflexes
- normalized serum sodium level (135–146 mEq/L)

Nursing Care of Patients with Hypernatremia

As with hyponatremia, nursing care for patients with hypernatremia focuses on monitoring the patient's condition and preventing associated neurological complications.

Recognizing and Analyzing Cues

In the early stages of hypernatremia, one of the only symptoms the patient may exhibit is thirst. As sodium levels increase, water moves out of cells, resulting in brain-cell shrinkage and signs such as confusion or seizures. Clinical manifestations associated with hyponatremia that should be assessed are listed in Table 10.8.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The main nursing intervention for patients with hypernatremia is monitoring accurate intake and output of fluid to prevent excessive gains or losses. Additionally, the nurse should encourage the patient to consume more water to dilute the excess sodium. If the patient is unable to drink fluids orally, fluid replacement with hypotonic solutions may be necessary. Just as with hyponatremia, fluid replacement should be performed slowly and cautiously. If sodium levels are decreased too quickly, water may move into brain cells and cause cerebral edema, which can quickly become life-threatening.

Evaluation of Nursing Care for Patients with Hyponatremia

After diagnosis of and initiation of treatment for hypernatremia, the nurse should evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment, the nurse should monitor the patient for signs and symptoms indicating that the sodium imbalance has been corrected. Signs and symptoms that would indicate an improvement in condition include

- improved mentation and level of consciousness
- normalized serum sodium level (135–146 mEq/L)
- normal thirst level

INTERDISCIPLINARY PLAN OF CARE

Interdisciplinary Care of a Patient with Electrolyte Imbalances

Care of the patient with electrolyte imbalances requires collaboration within an interdisciplinary team. Team members may play different roles, depending on the patient's needs. These may include

- dietitian: counsels patient about foods high and low in sodium and ensures patient has adequate education to make informed decisions about diet at home
- laboratory technician and/or phlebotomist: collects blood and/or urine specimens, and obtains or conducts testing, and provides the results
- nurse: implements care at patient's bedside
- ordering provider: oversees care plan and makes decisions about care goals
- pharmacist: oversees prescription medications and IV fluid orders to determine correct medication, dose, route, and so forth
- physical therapist: may show patient how to move to improve circulation and blood flow and urinary output

- social worker: connects patient with necessary resources outside of hospital

Calcium Overview

Calcium levels in the body normally range from 8.6 to 10.2 mg/dL, though this may vary depending on the institution's specific protocol. Calcium circulates in the bloodstream, but the majority is stored in bones. Calcium is important for maintaining bone and teeth structure, as well as in nerve transmission and muscle contraction. Calcium excretion and reabsorption are regulated by the parathyroid hormone (PTH), which is secreted from the parathyroid glands near the thyroid. As PTH is secreted in response to low calcium levels in the blood, calcium is reabsorbed in both the kidneys and the intestine and released from the bones to increase serum calcium levels. Calcium is also affected by dietary intake and physical activity. Physical activity causes calcium to move into bones, whereas immobility causes the release of calcium from bones, making them weaker.

Calcium Imbalances

In calcium imbalances, there is either too much calcium present in the blood (hypercalcemia) or too little (hypocalcemia). Both types require early assessment and intervention to prevent associated adverse effects.

A decreased calcium level in the blood is known as **hypocalcemia**. This imbalance can be caused by hypoparathyroidism, in which not enough PTH is excreted; as a result, the reabsorption of calcium and its release from the bones both decrease. Hypocalcemia is also caused by vitamin D deficiency and renal disease. Because phosphorus is inversely related to calcium, an abnormally high phosphorus level, as seen with renal failure, can also result in hypocalcemia.

An increased calcium level in the blood is known as **hypercalcemia**. It can be caused by prolonged immobilization that allows calcium to seep out of the bones and into the serum. Additionally, many types of cancers may cause excessive calcium release from bones. And because both hyperparathyroidism and parathyroid tumors can increase PTH secretion, they can also cause hypercalcemia, because too much calcium is reabsorbed in the kidneys and intestines and released from bone.

Table 10.9 compares the clinical manifestations of and diagnostic tests and treatments for both types of calcium imbalance.

	Hypocalcemia	Hypercalcemia
Pathophysiology	• Hypoparathyroidism decreases reabsorption of calcium and its release from bones. • Phosphorus is inversely related to calcium, so in cases of hyperphosphatemia (e.g., in renal failure), hypocalcemia may occur.	• Prolonged immobilization allows calcium to seep out of bones and into serum, or some types of cancers may cause excessive calcium release from bones. • Hyperparathyroidism and parathyroid tumors can increase PTH secretion; thus, they can also cause hypercalcemia because too much calcium is reabsorbed and released from bones.
Clinical manifestations	• Dyspnea • Hyperactive bowel sounds • Muscle cramps • Paresthesia (especially around the lips, tongue, hands, and feet) • Positive Chvostek's and Trousseau's signs (Figure 10.11) • Seizures • Tetany	• Constipation • Increased thirst or urination • Nausea and vomiting • Skeletal muscle weakness
Diagnostic tests	• Serum calcium level (<8.6 mg/dL) • ECG may show prolonged QT interval	• Serum calcium level (>10.2 mg/dL)
Treatments	• Administration of medications to lower phosphorus level if elevated • Increased dietary intake of calcium and vitamin D • IV calcium replacement (e.g., calcium gluconate, calcium chloride) • Treat underlying cause	• Decrease calcium intake in the diet • Hemodialysis for severe, refractory cases • Phosphate supplementation (oral and/or IV) • Treat underlying cause (e.g., surgical removal of parathyroid gland)

TABLE 10.9 **Hypocalcemia and Hypercalcemia**

Nursing Care of Patients with Hypocalcemia

Nursing care for patients with hypocalcemia should focus on monitoring the patient's condition and preventing associated complications, especially the development of seizures.

Recognizing and Analyzing Cues

In the early stages of hypocalcemia, the patient may be asymptomatic, especially if the drop in calcium levels is gradual. More acute or severe cases of hypocalcemia result in a state of increased neuromuscular excitability; thus, some of the first signs the nurse might notice are hyperactive reflexes and involuntary muscle contractions, or **tetany**. These include **Chvostek's sign**, an involuntary twitching of facial muscles when the facial nerve is tapped, and **Trousseau's sign**, a hand spasm caused by inflating a blood pressure cuff to a level above systolic pressure for 3 minutes. Figure 10.11 illustrates both these signs. Other clinical manifestations associated with hypocalcemia

that should be assessed are listed in Table 10.9.

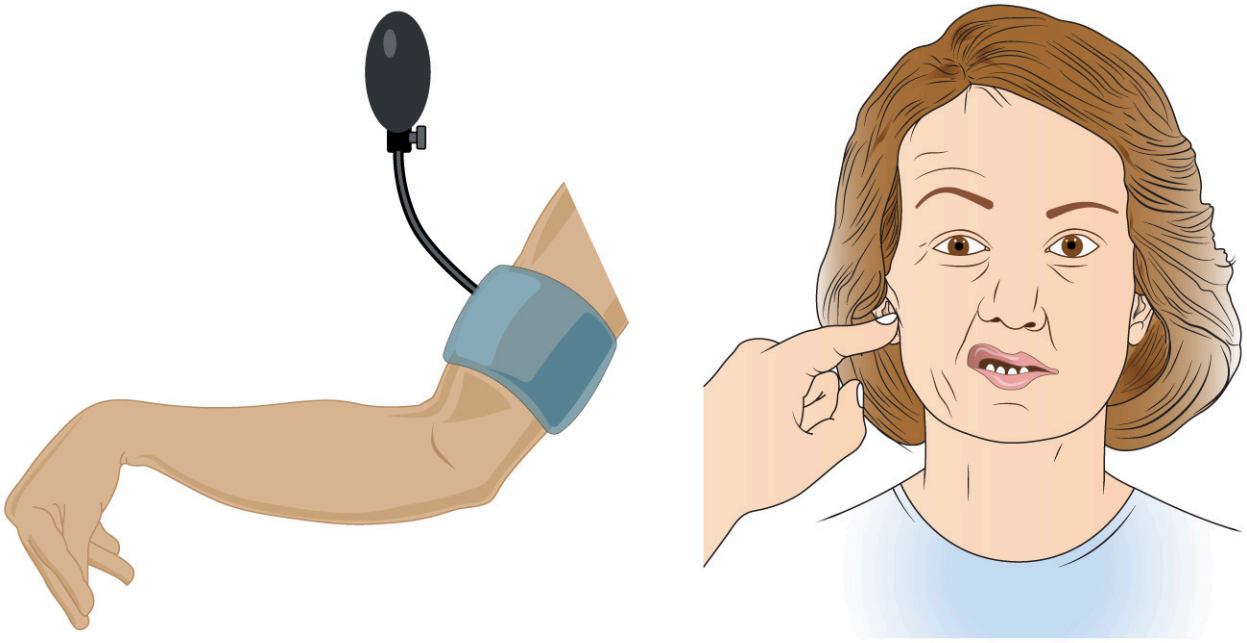

FIGURE 10.11 Positive (a) Chvostek's sign and (b) Trousseau's sign are both associated with hypocalcemia. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The main nursing intervention for a patient with hypocalcemia is the implementation of seizure precautions. Seizures are one of the most common serious effects of a low calcium level, so prophylactic prevention of injury from seizures is important. This includes padding the side rails of the patient's bed with seizure pads and ensuring that suction equipment is located within arm's reach of the bedside, per hospital protocol. Additionally, the nurse should educate the patient about foods they can consume in their diet to increase calcium levels (e.g., dairy products, green leafy vegetables, whole grains).

Evaluation of Nursing Care for Patients with Hypocalcemia

After diagnosis of and initiation of treatment for hypocalcemia, it is important for the nurse to evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment for hypocalcemia, the nurse should monitor the patient for signs indicating that calcium imbalance has been corrected. Signs that would indicate an improvement in condition include

- normal reflexes
- no seizure activity noted
- normal serum calcium level (8.6–10.2 mg/dL)

Nursing Care of the Patient with Hypercalcemia

Nursing care for patients with hypercalcemia should focus on monitoring the patient's condition and preventing associated complications.

Recognizing and Analyzing Cues

In the early stages of hypercalcemia, the patient may be asymptomatic, especially if the increase in calcium levels is gradual. More acute or severe cases of hypocalcemia result mostly in adverse GI signs and symptoms such as nausea and vomiting. Other clinical manifestations associated with hypercalcemia that should be assessed are listed in Table 10.9.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

One of the main nursing interventions for patients with hypercalcemia includes educating the patient about ways to decrease the intake of calcium in their diet and ensuring they consume enough phosphorus. Additionally, because

prolonged immobilization is a major cause of hypercalcemia, it is important that the nurse encourages the patient to ambulate as frequently as possible to prevent the release of even more calcium from the bones.

Evaluation of Nursing Care for Patients with Hypercalcemia

After diagnosis of and initiation of treatment for hypercalcemia, it is important for the nurse to evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment for hypercalcemia, the nurse should monitor the patient for signs indicating the calcium imbalance has been corrected. Signs that would indicate an improvement in condition include

- improved muscle weakness
- lack of GI symptoms
- normal serum calcium level (8.6–10.2 mg/dL)

Magnesium Overview

Magnesium is essential for normal cardiac, nerve, muscle, and immune system functioning. Magnesium levels typically range from 1.5 to 2.4 mEq/L; about half of the body's supply is stored in the bones. Dietary sources of magnesium include green leafy vegetables, citrus, peanut butter, almonds, legumes, and chocolate.

Magnesium Imbalances

In magnesium imbalances, there is either too much magnesium present in the blood (hypermagnesemia) or too little (hypomagnesemia). Both types require early assessment and intervention to prevent severe adverse effects, including cardiac dysrhythmias or arrest.

A decreased magnesium level in the blood is referred to as **hypomagnesemia**. It typically results from inadequate magnesium in the diet or from the use of loop diuretics that result in excretion of magnesium in urine. Additionally, patients with alcohol use disorder often have hypomagnesemia due to concurrent poor diet and impaired nutrient absorption that occurs with alcohol consumption. Chronic use of a proton pump inhibitor can also cause hypomagnesemia, due to impaired nutrient absorption.

An elevated magnesium level in the blood is known as **hypermagnesemia**. It is usually the result of renal failure, excess magnesium replacement, or the use of magnesium-containing laxatives or antacids. Table 10.10 compares the pathophysiology and clinical manifestations of, and diagnostic tests and treatments for both types of imbalances.

	Hypomagnesemia	Hypermagnesemia
Pathophysiology	Increased excretion of magnesium (e.g., with use of diuretics; cases of chronic alcohol use, laxative abuse, cancer, acute pancreatitis, malnutrition)	Decreased renal excretion of magnesium (e.g., as in kidney failure), excessive intake or replacement of magnesium (e.g., overuse of laxatives or antacids containing magnesium)
Clinical manifestations	• Cardiac dysrhythmias • Leg cramps • Lethargy and weakness • Nausea and vomiting • Tetany • Tremors	• Asystole • Bradycardia • Laxative abuse • Muscle weakness • Nausea • Slow reflexes • Tremors

TABLE 10.10 Hypomagnesemia and Hypermagnesemia

	Hypomagnesemia	Hypermagnesemia
Diagnostic tests	• Serum magnesium level (<1.5 mEq/L) • ECG may show premature ventricular contractions, flat or inverted T waves, or prolonged PR interval.	• Serum magnesium level (>2.4 mEq/L) • ECG may show peaked T waves.
Treatments	• Increase dietary magnesium intake • Oral or IV magnesium supplements (IV magnesium recommended for patients with torsade de pointes as a last-resort treatment option) • Treat underlying cause	• Dialysis for severe, refractory cases • Increase fluid intake • Stop medications containing magnesium • Treat underlying cause

TABLE 10.10 Hypomagnesemia and Hypermagnesemia

Nursing Care of Patients with Hypomagnesemia

Nursing care for patients with hypomagnesemia should focus on monitoring the patient's condition and preventing associated complications, especially the development of deadly cardiac dysrhythmias.

Recognizing and Analyzing Cues

When there is a low level of magnesium in the blood, there are often also low levels of calcium and potassium. Because of this, the nurse should monitor for clinical manifestations of hypomagnesemia and those of hypocalcemia and hypokalemia. Alterations in magnesium can cause cardiac dysrhythmias; therefore, it is important that the nurse monitors for subtle changes in the ECG that may indicate a worsening condition.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The nurse should place patients with hypomagnesemia on continuous telemetry monitoring to catch any changes that may indicate the development of severe cardiac dysrhythmias. Other main nursing interventions for this imbalance include monitoring intake and output, administering oral or IV magnesium supplements, and regularly monitoring all electrolyte values, because they tend to influence one another.

Evaluation of Nursing Care for Patients with Hypomagnesemia

After diagnosis of and initiation of treatment for hypomagnesemia, it is important for the nurse to evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment, the nurse should monitor the patient for signs indicating magnesium imbalance has been corrected. Signs that would indicate an improvement in condition include

- no reported adverse GI symptoms
- normal ECG
- normal reflexes

Nursing Care of Patients with Hypermagnesemia

Like nursing care for patients with hypomagnesemia, care of patients with hypermagnesemia should focus on monitoring the patient's condition and preventing associated complications.

Recognizing and Analyzing Cues

Symptoms of hypermagnesemia can be nonspecific and vague, making it difficult to diagnose without checking serum electrolyte levels. Some of the first signs of this imbalance include muscle weakness and decreased reflexes. Other signs to monitor for are listed in Table 10.10.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The nurse should place patients with hypermagnesemia on continuous telemetry monitoring to catch any changes that may indicate the development of severe cardiac dysrhythmias, especially complete heart block. Other nursing interventions for this imbalance include monitoring intake and output, encouraging oral fluid intake, and educating the patient about stopping medications that contain high levels of magnesium.

Evaluation of Nursing Care for Patients with Hypermagnesemia

After diagnosis of and initiation of treatment for hypermagnesemia, it is important for the nurse to evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment, the nurse should monitor the patient for signs indicating the magnesium imbalance has been corrected. Signs that would indicate an improvement in condition include

- improved muscle weakness
- normal ECG
- normal reflexes

Phosphorous Overview

Phosphorus is important in energy metabolism, RNA and DNA formation, nerve function, muscle contraction, and the building and repair of bone, teeth, and membranes. Phosphorus levels typically range from 2.5 to 4.0 mg/dL. The electrolyte is stored in the bones, excreted by the kidneys, absorbed by the intestines, and predominantly found in the intraocular fluid compartment.

Phosphorus Imbalances

In phosphorus imbalances, there is either too much phosphorus present in the blood (hyperphosphatemia) or too little (hypophosphatemia).

A decreased phosphorus level in the blood is referred to as **hypophosphatemia**. Acute hypophosphatemia can be caused by acute alcohol abuse, burns, diuretic use, respiratory alkalosis, and starvation. Chronic hypophosphatemia can be caused by hyperparathyroidism, vitamin D deficiency, prolonged use of phosphate binders, and hypomagnesemia or hypokalemia.

An increased phosphorus level in the blood is known as **hyperphosphatemia**. It can be caused by kidney disease, crush injuries, or overuse of phosphate-containing enemas. Table 10.11 compares the clinical manifestations of and diagnostic tests and treatments for both types of phosphorus imbalances.

	Hypophosphatemia	Hyperphosphatemia
Pathophysiology	• Movement of phosphorus out of vessels, often due to alcohol abuse, burns, diuretics, and starvation	• Overuse of medications containing phosphate • Crush injuries cause release of phosphorus into vessels. • Kidney disease impairs the kidneys' ability to process and excrete phosphorus.
Clinical manifestations	• Often asymptomatic • Severe cases may result in muscle weakness, encephalopathy, seizures, and death.	• Often asymptomatic • Can cause signs of hypocalcemia due to the inverse relationship between phosphorus and calcium.

TABLE 10.11 **Hypophosphatemia and Hyperphosphatemia**

	Hypophosphatemia	Hyperphosphatemia
Diagnostic tests	• Serum phosphorus level (<2.5 mg/dL)	• Serum phosphorus level (> 4.0 mg/dL)
Treatments	• Increase intake of phosphorus in the diet • Oral or IV phosphorus replacement • Treat underlying cause	• Administration of phosphate-binder medications • Decrease dietary intake of phosphorus • Hemodialysis • Treat underlying cause

TABLE 10.11 Hypophosphatemia and Hyperphosphatemia

Nursing Care of the Patient with Phosphorus Imbalances

Phosphorus imbalances are difficult to diagnose without obtaining a serum electrolyte level, because patients with phosphorus imbalance are often asymptomatic. For that reason, it is important for the nurse to be mindful of the patient's baseline status and investigate any small deviations that may indicate an electrolyte imbalance.

Recognizing and Analyzing Clues

Because phosphorus has an inverse relationship with calcium, the nurse may also want to monitor for associated signs and symptoms that may indicate the presence of another imbalance. For example, a patient with hypophosphatemia may be asymptomatic for a decreased level of phosphorus but may have signs or symptoms of hypercalcemia.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The main nursing interventions when caring for patients with phosphorus imbalances include monitoring serum electrolyte levels regularly, recording accurate intake and output, and treating each disorder appropriately. These patients will need education about dietary choices to ensure they are getting enough (or decreasing the amount of) phosphorus in their diet.

Evaluation of Nursing Care for Patients with a Phosphorus Imbalance

After diagnosis of and initiation of treatment for a phosphorus imbalance, it is important for the nurse to evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment, the nurse should monitor the patient for signs indicating the patient is improving. Signs that would indicate an improvement in condition include normalized serum phosphorus level (2.5–4.0 mg/dL) and normal vital signs.

Chloride Overview

Chloride is one of the main electrolytes in the extracellular fluid compartment; the normal range in blood samples is 97–107 mEq/L. Chloride is a major contributor to the osmotic pressure gradient between the intracellular and extracellular fluid compartments. Chloride is also important for maintaining proper hydration and acid-base balance in the body. Because chloride is an anion, meaning it is negatively charged, it is attracted to sodium, a positively charged cation. Consequently, these two electrolytes have a direct relationship: if sodium levels are low, chloride levels probably are as well. Chloride has an inverse relationship with bicarbonate, meaning that an increase in bicarbonate levels in the body results in a decrease in chloride levels.

Chloride Imbalances

With chloride imbalances, there is either too much chloride present in the blood (hyperchloremia) or too little (hypochloremia). Both types require early assessment and intervention to prevent severe adverse effects.

A decreased chloride level in the blood is known as **hypochloremia**. Common causes of hypochloremia include

- diuretic use
- fluid overload (e.g., from congestive heart failure)

- GI loss of chloride, such as with prolonged vomiting or diarrhea
- low dietary sodium intake
- metabolic alkalosis

An increased chloride level in the blood is known as **hyperchloremia**. Common causes of hyperchloremia include

- corticosteroid use
- fluid loss (e.g., vomiting, frequent urination)
- high intake of sodium in the diet or excessive administration of normal saline
- metabolic acidosis

Table 10.12 compares the pathophysiology and clinical manifestations of and diagnostic tests and treatments for both types of chloride imbalances.

	Hypochloremia	Hyperchloremia
Pathophysiology	Increased excretion of chloride (e.g., with prolonged vomiting or diarrhea, use of diuretics), dilution (e.g., with fluid overload), or increased bicarbonate levels (e.g., in metabolic alkalosis)	Increased sodium levels or hemoconcentration (related to fluid loss such as with vomiting or excessive urination)
Clinical manifestations	• Agitation or irritability • Coma • Hyperactive reflexes • Muscle cramps • Seizures • Slow and/or shallow respirations • Tetany • Tremors	• Coma • Deep, rapid respirations • Lethargy • Tachycardia • Weakness
Diagnostic tests	• Arterial blood gas findings indicate metabolic alkalosis • Serum chloride level (<97 mEq/L) • Serum sodium level decreased	• Arterial blood gas findings indicate metabolic acidosis • Serum chloride level (>107 mEq/L) • Serum sodium level increased
Treatments	• Discontinue diuretics, if possible • IV normal saline or 0.45% normal saline to replace lost chloride • Treat underlying cause	• Diuretics to promote chloride excretion in the urine • Hypotonic IV fluid administration • Sodium and fluid restrictions • Treat underlying cause

TABLE 10.12 Hypochloremia and Hyperchloremia

Nursing Care of Patients with Chloride Imbalances

Nursing care for patients with chloride imbalances should focus on monitoring the patient's condition and preventing associated complications, especially the development of severe acid-base imbalances.

Recognizing and Analyzing Cues

It is important for the nurse to understand the relationship between chloride and other electrolytes. Specifically, if a

patient is experiencing a sodium imbalance, the nurse should investigate the patient's chloride balance as well, because the two electrolytes have a direct relationship. Because of this relationship, clinical manifestations between hyponatremia and hypochloremia may be similar, because they often occur at the same time. This is also true of hypernatremia and hyperchloremia.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The main nursing interventions for patients with chloride imbalances include

- closely monitoring respiratory and neurological status for deviations from baseline that would indicate worsening of the imbalance
- monitoring and recording accurate intake and output
- monitoring and treating acid-base imbalances
- monitoring vital signs

Evaluation of Nursing Care for Patients with Chloride Imbalances

After diagnosis of and initiation of treatment for a chloride imbalance, it is important for the nurse to evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment, signs that would indicate the patient's condition is improving include

- improved mental status
- normal reflexes
- normal serum chloride level (97–107 mEq/L)

10.4 Acid-Base Imbalance

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology and clinical manifestations of acid-base imbalances
- Describe the diagnostics and laboratory values related to acid-base imbalances
- Apply nursing concepts and plan associated nursing care for patients with acid-base imbalances
- Evaluate the efficacy of nursing care for patients with acid-base imbalances
- Describe the medical therapies that apply to the care of acid-base imbalances

As with electrolytes, the correct balance of acids and bases in the body is essential to proper functioning. Even a slight variance outside of normal can be life-threatening, so it is important to understand normal acid-base values, as well the causes of imbalances and how to correct them. The kidneys and lungs work together to correct slight imbalances as they occur. As a result, the kidneys compensate for imbalances arising from the lungs, and the lungs compensate for imbalances arising from the kidneys. However, over time, these compensatory mechanisms tire out and acid-base imbalances develop.

Arterial Blood Gases

Acid-base balance is measured on the pH scale, as shown in Figure 10.12. The value that explains how much hydrogen is contained within a liquid and the activity of the hydrogen ion is its **pH** (potential hydrogen). As a review, **acid** is a byproduct of many metabolic processes in the body and form hydrogen (H^+) ions when dissolved in water. With higher acidity in the body, the overall pH of the body is lower. On the other hand, **bases** form hydroxide (OH^-) ions when dissolved in water, and more bases in the body (increased alkalinity) result in a higher pH. An **arterial blood gas (ABG)** is procedure in which blood is obtained from an arterial catheter or direct puncture and then analyzed to determine oxygenation status. Samples are most commonly collected via the radial artery. Arterial blood gases are indicators of several parameters that can affect the body's acid-base balance: the pH level of the blood, the partial pressure of arterial oxygen (PaO_2), the partial pressure of arterial carbon dioxide ($PaCO_2$), the bicarbonate level (HCO_3^-), and the oxygen saturation level (SaO_2). Normal values for each of these parameters are listed in Table 10.13. It is important that nurses understand how to interpret ABG results because correct interpretation helps determine the appropriate treatment and evaluate the effectiveness of interventions.

pH	Examples of solutions
0	Battery acid, strong hydrofluoric acid
1	Hydrochloric acid secreted by stomach lining
2	Lemon juice, gastric acid, vinegar
3	Grapefruit juice, orange juice, soda
4	Tomato juice, acid rain
5	Soft drinking water, black coffee
6	Urine, saliva
7	"Pure" water
8	Sea water
9	Baking soda
10	Great Salt Lake, milk of magnesia
11	Ammonia solution
12	Soapy water
13	Bleach, oven cleaner
14	Liquid drain cleaner

FIGURE 10.12 This chart shows where many common substances fall on the pH scale. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Parameter	Normal Range
pH	7.35–7.45
Partial pressure of oxygen (Pao_2)	80–100 mm Hg
Partial pressure of carbon dioxide ($Paco_2$)	35–45 mm Hg
Bicarbonate (HCO_3^-)	22–26 mEq/L
Oxygen saturation (Sao_2)	95%–98%

TABLE 10.13 **Normal ABG Values**

Interpreting ABGs

Arterial blood gas values can be interpreted to indicate one of four conditions: respiratory acidosis, respiratory alkalosis, metabolic acidosis, or metabolic alkalosis. Once this interpretation is made, conditions can further be

classified as compensated, partially compensated, or uncompensated, depending on whether an internal compensatory mechanism is attempting to correct the imbalance in the body. Compensation is indicated by certain changes in ABG values.

A simple way to remember how to interpret ABG values is the acronym ROME, which stands for Respiratory Opposite, Metabolic Equal. This means that the respiratory component ($PaCO_2$) moves in the opposite direction of the pH if the respiratory system is causing the imbalance. If the metabolic system is causing the imbalance, the metabolic component (HCO_3) moves in the same direction as the pH.

LINK TO LEARNING

This video reviews the Tic-Tac-Toe Method of ABG Interpretation (https://openstax.org/r/77abginterpret) which some nurses find helpful.

Metabolic Acidosis

Under normal conditions, the kidneys work to maintain a normal pH by excreting acids through urine; they also neutralize excess acids by increasing bicarbonate (HCO_3^-) reabsorption from the urine. When the kidneys are not able to perform this buffering function to the level required to excrete and neutralize the excess acid, acids accumulate (in the form of hydrogen ions) and there is a deficiency of bases (in the form of bicarbonate). This condition is called **metabolic acidosis**.

Metabolic acidosis is characterized by a pH level below 7.35 and an HCO_3 level below 22 mEq/L. It is important to notice that both the pH and HCO_3 decrease with metabolic acidosis (i.e., they move in the same downward direction).

Pathophysiology of Metabolic Acidosis

A common cause of metabolic acidosis is diabetic ketoacidosis. In diabetic ketoacidosis, acids called ketones, a byproduct of anaerobic metabolic due to a lack of insulin, are detected and excreted in the urine. Another common cause in hospitalized patients is lactic acidosis, which can be caused by impaired tissue oxygenation. Metabolic acidosis can also be caused by increased loss of bicarbonate due to severe diarrhea or from renal disease that impairs the kidneys' ability to eliminate acid.

Clinical Manifestations of Metabolic Acidosis

Nurses may first suspect that a patient has metabolic acidosis because the patient has rapid breathing; this occurs as the lungs try to remove excess CO_2 to resolve the acidosis. Other signs and symptoms of metabolic acidosis include

- confusion
- decreased level of consciousness
- electrolyte disturbances that can progress to circulatory collapse and death if not treated promptly
- GI distress: diarrhea
- hypotension

Medical Therapies and Related Care

It is important to quickly notify the provider of suspected metabolic acidosis so that an ABG measurement can be ordered, a sample collected, and treatment prescribed (based on the cause of the metabolic acidosis) to allow acid levels to improve. Treatment includes IV fluids to improve hydration status, tight glucose management, and circulatory support. When the pH drops below 7.1, IV sodium bicarbonate is often prescribed to help neutralize the acids in the blood.

Metabolic Alkalosis

When there is too much HCO_3 in the body or an excessive loss of acid (in the form of hydrogen ions) it is known as **metabolic alkalosis**. The condition is defined by a pH above 7.45 and a bicarbonate level above 26 on ABG results. Note that both pH and HCO_3^- level are elevated in metabolic alkalosis.

Pathophysiology of Metabolic Alkalosis

Metabolic alkalosis has a variety of causes, including prolonged vomiting and nasogastric suctioning. This is because gastric secretions have high levels of hydrogen ions: as acid is lost, the pH level of the bloodstream increases. Excessive urinary loss (due to diuretics or excessive mineralocorticoids) can cause metabolic alkalosis due to loss of hydrogen ions in the urine. Intravenous administration of sodium bicarbonate can also cause metabolic alkalosis due to increased levels of bases introduced into the body.

Metabolic alkalosis can also happen when hydrogen ions shift into cells due to hypokalemia. Recall that hypokalemia refers to low levels of potassium in the bloodstream. When this happens, potassium ions shift out of cells and into the bloodstream to maintain a normal level of serum potassium for optimal cardiac function. However, as the potassium ions (K^+) move out of cells, H^+ moves into the cells from the bloodstream to maintain electrical neutrality. This transfer of ions causes the pH in the bloodstream to rise resulting in metabolic alkalosis.

Clinical Manifestations of Metabolic Alkalosis

A nurse may first suspect that a patient has metabolic alkalosis because they may have a decreased respiratory rate; this is the result of the lungs trying to retain additional CO_2 to increase the acidity of the blood and resolve the alkalosis. The patient may also be confused due to the altered pH level. The nurse should report signs of suspected metabolic alkalosis because the condition, if uncorrected, can result in hypotension and cardiac dysfunction. Additionally, any fluid loss from the stomach level and above results in loss of acids and eventual alkalosis, whereas fluid losses below the stomach result in loss of bases and eventual acidosis. For example, prolonged vomiting can result in alkalosis and prolonged diarrhea can result in acidosis.

Medical Therapies and Related Care

Treatment for metabolic alkalosis is prescribed on the basis of the ABG results and the suspected cause. For example, orders may include treating the cause of the vomiting, stopping the GI suctioning, or stopping the administration of diuretics. If hypokalemia is also present, it should be promptly treated. If bicarbonate is being administered, it should be stopped. Patients with kidney disease or severe imbalances may require dialysis.

Respiratory Alkalosis (Carbonic Acid Deficit)

When the body removes too much CO_2 through respiration, resulting in increased pH and an alkalotic state, it is known as **respiratory alkalosis**. When reviewing ABG values, respiratory alkalosis is identified when pH levels are above 7.45 and the $PaCO_2$ level is below 35. Notice that as the $PaCO_2$ level decreases, the pH level increases.

Pathophysiology of Respiratory Alkalosis

Respiratory alkalosis is caused by hyperventilation that can occur due to anxiety, panic attacks, pain, fear, head injuries, or mechanical ventilation. Overdoses of salicylates and other toxins can also cause respiratory alkalosis initially; the condition often progresses to metabolic acidosis in later stages. Acute asthma exacerbations, pulmonary embolisms, or other respiratory disorders can initially cause respiratory alkalosis as the lungs breathe faster in an attempt to increase oxygenation, which decreases the $PaCO_2$. After a while, however, these hypoxic disorders cause respiratory acidosis, as respiratory muscles tire, breathing slows, and CO_2 builds up in the blood.

Clinical Manifestations of Respiratory Alkalosis

Patients experiencing respiratory alkalosis often report feelings of shortness of breath, dizziness or light-headedness, chest pain or tightness, paresthesia, and palpitations. These symptoms result from decreased CO_2 levels. Respiratory alkalosis is not fatal, but it is important to recognize that underlying conditions such as asthma exacerbation or pulmonary embolism can be life-threatening, so treatment of these underlying conditions is essential.

Medical Therapies and Related Care

As the body's pH level increases, the kidneys attempt to compensate for the shortage of hydrogen ions by reabsorbing bicarbonate before it can be excreted in the urine. This is a slow process, so additional treatment may be necessary to address the underlying cause of hyperventilation. Acute management of patients who are hyperventilating should focus on patient reassurance, an explanation of the symptoms the patient is experiencing, and the removal of any stressors.

Respiratory Acidosis (Carbonic Acid Excess)

When CO_2 builds up in the body, **respiratory acidosis** develops, a condition known as **hypercapnia**, which causes the blood to become increasingly acidic. Respiratory acidosis is identified when ABG measurements show a pH level below 7.35 and $PaCO_2$ level above 45; these data indicate the cause of the acidosis is respiratory. Note that in respiratory acidosis, as the $PaCO_2$ level increases, the pH level decreases.

Pathophysiology of Respiratory Acidosis

Respiratory acidosis is typically caused by a medical condition such as an acute asthma exacerbation, COPD, or an acute heart failure exacerbation causing pulmonary edema; these conditions all decrease the exchange of oxygen and CO_2 at the alveolar level. Respiratory acidosis can also be caused by decreased ventilation from anesthesia, the consumption of alcohol, or the administration of medications such as opioids and sedatives.

Chronic respiratory diseases, such as COPD, often cause chronic respiratory acidosis that is fully compensated for by the kidneys retaining HCO_3^-. Because the CO_2 levels build up over time, the body adapts to elevated $PaCO_2$ levels, and they are better tolerated. However, in acute respiratory acidosis, the body does not have time to adapt to elevated CO_2 levels, causing mental status changes associated with hypercapnia. Acute respiratory acidosis is caused by acute respiratory conditions, such as an asthma attack or heart failure exacerbation with pulmonary edema, when the lungs suddenly are not able to ventilate adequately. As breathing slows and respirations become shallow, less CO_2 is excreted by the lungs and $PaCO_2$ levels quickly rise.

Clinical Manifestations of Respiratory Acidosis

Signs and symptoms of hypercapnia vary depending upon the level and rate of CO_2 accumulation in arterial blood. Patients with mild to moderate hypercapnia may be anxious or complain of mild dyspnea, daytime sluggishness, headaches, or hypersomnolence. Patients with higher levels of CO_2 or rapidly developing hypercapnia may develop delirium, paranoia, depression, and confusion that can progress to seizures and coma as levels continue to increase. Individuals with normal lung function typically exhibit a depressed level of consciousness when the $PaCO_2$ is greater than 75 to 80 mm Hg, whereas patients with chronic hypercapnia may not develop symptoms until the $PaCO_2$ is greater than 90 to 100 mm Hg.

Medical Therapies and Related Care

When a patient demonstrates signs of potential hypercapnia, the nurse should assess airway, breathing, and circulation. Urgent assistance should be sought, especially if the patient is in respiratory distress. The provider should order an ABG measurement and prescribe treatments based on assessment findings and potential causes. Treatment for respiratory acidosis typically involves improving ventilation and respiration by removing airway restrictions, reversing oversedation, administering nebulizer treatments, or increasing the rate and depth of respiration by using a bilevel positive airway pressure (BiPAP) or continuous positive airway pressure (CPAP) device. BiPAP and CPAP devices provide noninvasive positive pressure ventilation to increase the depth of respiration, remove CO_2, and oxygenate the patient. If these noninvasive interventions are not successful, the patient will likely need to be intubated and receive mechanical ventilation support.

Nursing Care of Patients with Acid-Base Imbalances

Nursing care for patients with acid-base imbalances focuses on early detection and intervention to ensure optimal patient outcomes. Even slight alterations in acid-base balance can significantly alter the body's homeostasis and result in dysfunctional physiological processes.

Recognizing and Analyzing Cues

For patients presenting with signs and symptoms indicating the presence of an acid-base imbalance, one of the first interventions is to obtain an ABG measurement. The respiratory therapist (RT) often performs this, which highlights the importance of interdisciplinary collaboration and teamwork. On the basis of the findings of the ABG sample, the nurse, RT, and provider will work together to determine the next step and develop an appropriate plan of care for the patient.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The main nursing interventions for patients with acid-base imbalances include

- closely monitoring respiratory and neurological status for deviations from baseline that would indicate

worsening of the imbalance
- monitoring and recording accurate intake and output
- monitoring and treating the specific acid-base imbalance
- monitoring vital signs

Evaluation of Nursing Care for Patients with Acid-Base Imbalances

After diagnosis of and initiation of treatment for an acid-base imbalance, it is important for the nurse to evaluate patient outcomes to determine whether treatment was effective and if further intervention is necessary. After treatment, signs that would indicate the patient's condition is improving include

- normal ABG values
- normal serum electrolyte levels
- regular breathing pattern and adequate oxygenation

Compensation

Various compensatory mechanisms exist to maintain blood pH within a narrow range, including buffers, respiration, and renal mechanisms. Although compensatory mechanisms usually work very well, when one of these mechanisms is not working properly (e.g., as in kidney failure or respiratory disease), they have their limits. If the pH and bicarbonate to carbonic acid ratio are changed too drastically, the body may not be able to compensate. Moreover, extreme changes in pH can denature proteins. Extensive damage to proteins in this way can result in disruption of normal metabolic processes, serious tissue damage, and, ultimately, death.

Respiratory Compensation

Respiratory compensation for metabolic acidosis increases the respiratory rate to drive off CO_2 and readjust the bicarbonate to carbonic acid ratio to the 20:1 level. This adjustment can occur within minutes. The normal response of the respiratory system to elevated pH is to increase the amount of CO_2 in the blood by decreasing the respiratory rate to conserve CO_2. There is a limit to the decrease in respiration, however, that the body can tolerate. Hence, the respiratory route is less efficient at compensating for metabolic alkalosis than for acidosis.

Metabolic Compensation

Metabolic and renal compensation for respiratory diseases that can create acidosis revolves around the conservation of HCO_3^-. In cases of respiratory acidosis, the kidney increases the conservation of HCO_3^- and secretion of H^+ through exchange mechanisms. These processes increase the concentration of HCO_3^- in the blood, reestablishing the proper relative concentrations of HCO_3^- and carbonic acid. In cases of respiratory alkalosis, the kidneys decrease the production of HCO_3^- and reabsorb H^+ from the tubular fluid. These processes can be limited by the exchange of potassium by the renal cells, which use a K^+–H^+ exchange mechanism.

Summary

10.1 Maintaining Homeostasis

- To maintain homeostasis or stable internal equilibrium of physiological processes, the body must maintain appropriate balances of fluids, electrolytes, pH, acids, and bases.
- Body fluids are found in two main areas in the body: intracellular and extracellular compartments.
- The movement of fluid between intracellular and extracellular compartments is governed by several mechanisms, including hydrostatic pressure, oncotic pressure, and osmosis.
- The body has many internal mechanisms in place that attempt to compensate for fluid, electrolyte, and acid-base imbalances.
- When the body's compensatory mechanisms are not able to completely correct these imbalances, medical intervention is warranted.
- Two of the major compensatory mechanisms in the body include antidiuretic hormone (ADH) and the renin-angiotensin-aldosterone system (RAAS).

10.2 Fluid Disturbances and Replacement

- Both excessive and inadequate amounts of fluid can alter the body's homeostasis and become life-threatening if left untreated.
- Hypovolemia occurs when the loss of fluid is greater than fluid intake, resulting in a deficient amount of fluid volume in the body.
- The main goals of nursing care for patients with hypovolemia include restoring fluid balance to an optimal level, maintaining homeostasis, and preventing the development of complications such as hypovolemic shock.
- Three types of IV fluids are used to treat hypovolemia—isotonic, hypotonic, and hypertonic fluids—and they vary on the basis of their tonicity, or composition and concentration of dissolved particles.
- Hypervolemia, also known as fluid volume overload, occurs when an increased amount of fluid is retained in the intravascular compartment, resulting in excess fluid volume.
- The main goals of nursing care for patients with hypervolemia include removing excess fluid, maintaining homeostasis, and preventing the development of complications such as pulmonary edema.

10.3 Electrolyte Imbalance

- Electrolytes play an important role in most physiological body functions and assist in maintaining homeostasis.
- There is a very narrow target range for normal electrolyte values, and even slight abnormalities can have devastating consequences.
- Potassium imbalances are a high priority because they often result in fatal cardiac dysrhythmias if left untreated.
- In sodium imbalances, there is either too much sodium present in the blood (hypernatremia) or too little (hyponatremia). Both types are common and require early assessment and intervention to prevent severe adverse effects.
- Hypocalcemia (too little calcium in the blood) results in signs and symptoms including tetany, muscle cramps, and paresthesia; whereas hypercalcemia (too much calcium in the blood) causes nausea, vomiting, constipation, and increased thirst or urination.
- In magnesium imbalances, there is either too much magnesium present in the blood (hypermagnesemia) or too little (hypomagnesemia). Both types require early assessment and intervention to prevent severe adverse effects, including cardiac dysrhythmias or arrest.
- Hyperphosphatemia (too much phosphorus in the blood) is caused by conditions such as alcohol abuse, burns, diuretic use, and starvation; whereas hypophosphatemia (too little phosphorus in the blood) is caused by kidney disease, crush injuries, and overuse of phosphate-containing enemas.

10.4 Acid-Base Imbalance

- As with electrolytes, acids and bases must be correctly balanced for the body to function properly.
- The kidneys and lungs work together to correct acid-base imbalances as they occur. As a result, the kidneys compensate for shortcomings of the lungs, and the lungs compensate for shortcomings of the kidneys.

- Interpreting arterial blood gas values can indicate one of four conditions: respiratory acidosis, respiratory alkalosis, metabolic acidosis, or metabolic alkalosis.
- Metabolic acidosis occurs when there is an accumulation of acids (hydrogen ions) and not enough bases (bicarbonate) in the body.
- Metabolic alkalosis occurs when there is too much bicarbonate in the body or an excessive loss of hydrogen ions.
- Respiratory alkalosis develops when the body removes too much carbon dioxide through respiration, resulting in increased pH and an alkalotic state.
- Respiratory acidosis develops when carbon dioxide builds up in the body (a state known as hypercapnia), causing the blood to become increasingly acidic.

Key Terms

acid byproduct of many metabolic processes in the body and forms hydrogen ions (H^+) when dissolved in water
acidosis condition involving excessive levels of acids in the body
alkalosis condition involving excessive levels of bases in the body
arterial blood gas procedure in which blood is obtained from an arterial catheter or direct puncture and then analyzed to determine oxygenation status
ascites fluid accumulation in the abdominal cavity
baroreceptors specialized nerve cells that can detect the "stretch" (i.e., the level of vasoconstriction) of vessels, which reflects blood pressure
base forms hydroxide (OH^-) ions when dissolved in water
Chvostek's sign involuntary twitching of facial muscles when the facial nerve is tapped; a classic sign of acute hypocalcemia
edema swelling in the dependent tissues and extremities related to fluid accumulation in the interstitial space
electrolytes ions dissolved in body fluid that play important roles in most physiological functions and assist in maintaining homeostasis
hydrostatic pressure force exerted by a fluid against a wall, causing the movement of fluid between compartments
hypercalcemia increased level of calcium in the blood
hypercapnia elevated carbon dioxide levels in the blood
hyperchloremia increased level of chloride in the blood
hyperkalemia increased level of potassium in the blood
hypermagnesemia increased level of magnesium in the blood
hypernatremia increased level of sodium in the blood
hyperphosphatemia increased level of phosphorus in the blood
hypertonic describes a solution that contains more dissolved solutes than blood contains
hypervolemia a state that occurs when an increased amount of fluid is retained in the intravascular compartment, resulting in an excess volume of fluid
hypocalcemia decreased levels of calcium in the blood
hypochloremia decreased level of chloride in the blood
hypokalemia decreased level of potassium in the blood
hypomagnesemia decreased level of magnesium in the blood
hyponatremia decreased level of sodium in the blood
hypophosphatemia decreased level of phosphorus in the blood
hypothalamus structure in the brain that acts as a control center for the endocrine system
hypotonic describes a solution that contains fewer dissolved solutes than blood contains
hypovolemia state that occurs when fluid loss is greater than fluid intake, resulting in a deficient volume of fluid
hypovolemic shock life-threatening medical condition in which the heart cannot get enough blood and oxygen to body tissues due to a severe intravascular fluid deficit
isotonic describes a solution that contains the same number of dissolved solutes compared with blood
metabolic acidosis condition resulting from an accumulation of acids and a deficiency of bases in the bloodstream
metabolic alkalosis condition resulting from an accumulation of bases and a deficiency of acids in the bloodstream

oncotic pressure pressure created by colloid in a fluid; prevents the movement of water from one solution to another
osmolarity solute concentration of the blood
osmoreceptors specialized cells in the hypothalamus that are particularly sensitive to the concentration of sodium ions and other solutes
osmosis movement of water through a semipermeable membrane from an area of lesser solute concentration to an area of greater solute concentration
osmotic demyelination syndrome brain cell dysfunction that results from osmotic changes, often due to rapid correction of hyponatremia
osmotic pressure the pressure exerted by plasma proteins (e.g., albumin), acting as a pulling force to keep fluids inside blood vessels
pH value that explains how much hydrogen is contained within a liquid and the activity of the hydrogen ion
pulmonary edema life-threatening condition in which the respiratory system no longer functions effectively due to excessive fluid accumulation in the lungs
respiratory acidosis condition that develops when carbon dioxide builds up in the body, causing the blood to become increasingly acidic
respiratory alkalosis condition that develops when the body removes too much carbon dioxide through respiration, resulting in increased pH and an alkalotic state
solute substance dissolved in another substance
tetany involuntary contraction of muscles that is often related to hypocalcemia and leads to painful muscle cramps, spasms, and hyperactive reflexes
tonicity composition and concentration of dissolved solutes in a solution
Trousseau's sign hand spasm caused by inflating a blood pressure cuff to a level above systolic pressure for 3 minutes; a classic sign of acute hypocalcemia

Assessments

Review Questions

1. What kind of fluid is found in the intravascular space of the extracellular fluid compartment?
   a. plasma
   b. lymph
   c. synovial fluid
   d. cerebrospinal fluid

2. What force is exerted by plasma proteins in an effort to keep fluids inside the blood vessels and prevent them from leaking into the interstitial space?
   a. osmosis
   b. oncotic pressure
   c. hydrostatic pressure
   d. glomerular filtration

3. What situation would result in activation of the RAAS?
   a. hypokalemia
   b. hyponatremia
   c. elevated blood pressure
   d. increased serum osmolarity

4. A nurse is caring for a patient diagnosed with hypovolemia secondary to excessive vomiting. What clinical manifestation would the nurse anticipate?
   a. weight gain
   b. tachycardia
   c. bounding pulses
   d. jugular venous distension

5. What abnormal laboratory value would be most consistent with a diagnosis of hypervolemia?
   a. hyponatremia
   b. increased hematocrit
   c. increased serum osmolarity
   d. decreased serum creatinine

6. What fluid order would the nurse anticipate for a patient who presents with severe bleeding after a motor vehicle accident?
   a. 3% normal saline
   b. 5% normal saline
   c. 0.45% normal saline
   d. 0.9% normal saline

7. What nursing intervention is the priority when caring for a patient receiving oral potassium supplements?
   a. neurological checks
   b. telemetry monitoring
   c. fluid administration
   d. frequent turns

8. What is an assessment finding that a nurse would expect for a patient with a serum sodium level of 130 mEq/L?
   a. cardiac dysrhythmias
   b. weight loss
   c. hypertension
   d. seizures

9. What is a factor that increases the risk of developing hypercalcemia?
   a. prolonged immobility
   b. hypoparathyroidism
   c. vitamin D deficiency
   d. high intake of phosphorus

10. How should the nurse interpret these results? A nurse is caring for a patient with the following ABG results:
   - pH: 7.34
   - $PaCO_2$: 50 mm Hg
   - HCO_3^-: 26 mEq/L

   a. metabolic acidosis
   b. metabolic alkalosis
   c. respiratory acidosis
   d. respiratory alkalosis

11. What acid-base imbalance should a nurse anticipate in a patient who presents with diabetic ketoacidosis?
   a. metabolic acidosis
   b. metabolic alkalosis
   c. respiratory acidosis
   d. respiratory alkalosis

12. What acid-base imbalance should a nurse anticipate in a patient who presents with hyperventilation secondary to anxiety?
   a. metabolic acidosis
   b. metabolic alkalosis
   c. respiratory acidosis

d. respiratory alkalosis

Check Your Understanding Questions

1. What role do the kidneys play in maintaining the body's homeostasis?
2. What is the difference between baroreceptors and osmoreceptors?
3. What is the meaning of homeostasis?
4. What assessment findings would you expect to see in a patient diagnosed with hypervolemia?
5. What would the nurse be most concerned about when administering potassium intravenously?
6. Why are patients with COPD at high risk for developing respiratory acidosis?

Reflection Questions

1. What assessment findings in your patient would help confirm that the RAAS is working effectively?
2. Which acid-base imbalance is most likely to result in the need for intubation and mechanical ventilation? Why?

What Should the Nurse Do?

An emergency department nurse is caring for a patient who presents with shortness of breath. The patient reports that she was walking around the house and suddenly "couldn't catch my breath." She also reports that she forgot to take her "water pill" for the last week and feels like she has gained a few pounds because of it.

1. Based on the information provided, what condition do you think the patient has? What information led you to this conclusion?
2. What assessments should you perform on the patient?
3. What orders do you anticipate from the provider for this patient?
4. What outcomes would indicate that the orders were successful?

A nurse is caring for Ms. Chen, a 62-year-old female who presents to the emergency department after experiencing 2 days of severe nausea and vomiting. The patient also reports muscle cramping and excessive fatigue. After obtaining an ECG, the nurse notices the presence of U waves.

5. Which electrolyte imbalance should the nurse suspect on the basis of the patient's presentation and assessment findings?
6. What other signs and symptoms should the nurse assess for?
7. What treatment(s) and intervention(s) should the nurse anticipate?
8. What patient outcomes would indicate the treatments or interventions were effective?

A nurse is caring for Mr. Johnson, a 74-year-old male who presents to the emergency department with a COPD exacerbation. Upon assessment, the nurse notices that the patient is becoming more lethargic, and his oxygen saturation is only 87% despite being on 4 liters of supplemental oxygen. ABG results are as follows:

pH: 7.24
$PaCO_2$: 60 mm Hg
HCO_3^-: 25 mEq/L

9. Which acid-base imbalance should the nurse suspect on the basis of the patient's presentation and assessment findings?
10. What other symptoms should the nurse assess for?
11. What treatment(s) and intervention(s) should the nurse anticipate?
12. What patient outcomes would indicate the treatments or interventions were effective?

Competency-Based Assessments

1. A patient with chronic kidney disease is admitted to the hospital. How do the impaired functions of the kidneys affect the homeostasis of fluids and electrolytes in the body? Discuss potential nursing interventions.

2. As a clinical nurse, you are working with a patient who has been diagnosed with diabetes mellitus, a condition affecting the pancreas. What is the impact of impaired pancreatic function on both fluid balance and the body's ability to maintain homeostasis?
3. A patient is admitted with hypovolemia due to severe dehydration after a prolonged bout of vomiting. Describe the pathophysiology of hypovolemia, identify relevant risk factors, and outline the clinical manifestations a nurse should assess in this patient.
4. In the emergency department, you encounter a patient with severe hypovolemia due to gastrointestinal bleeding who needs fluid replacement. Discuss the factors you should consider when selecting the appropriate type and rate of fluid replacement.
5. As a nursing student, how would you assess the effectiveness of nursing care for a patient with hypernatremia?
6. A patient with electrolyte imbalances is receiving medical therapies, including IV potassium replacement and loop diuretics. Discuss the nursing considerations and potential complications associated with these therapies. How would you evaluate the efficacy of the nursing care provided?
7. Explain the interplay between the respiratory system (lungs) and the endocrine system in maintaining acid-base balance. How does this contribute to overall homeostasis?

CHAPTER 11

Gas Exchange, Airway Management, and Respiratory System Disorders

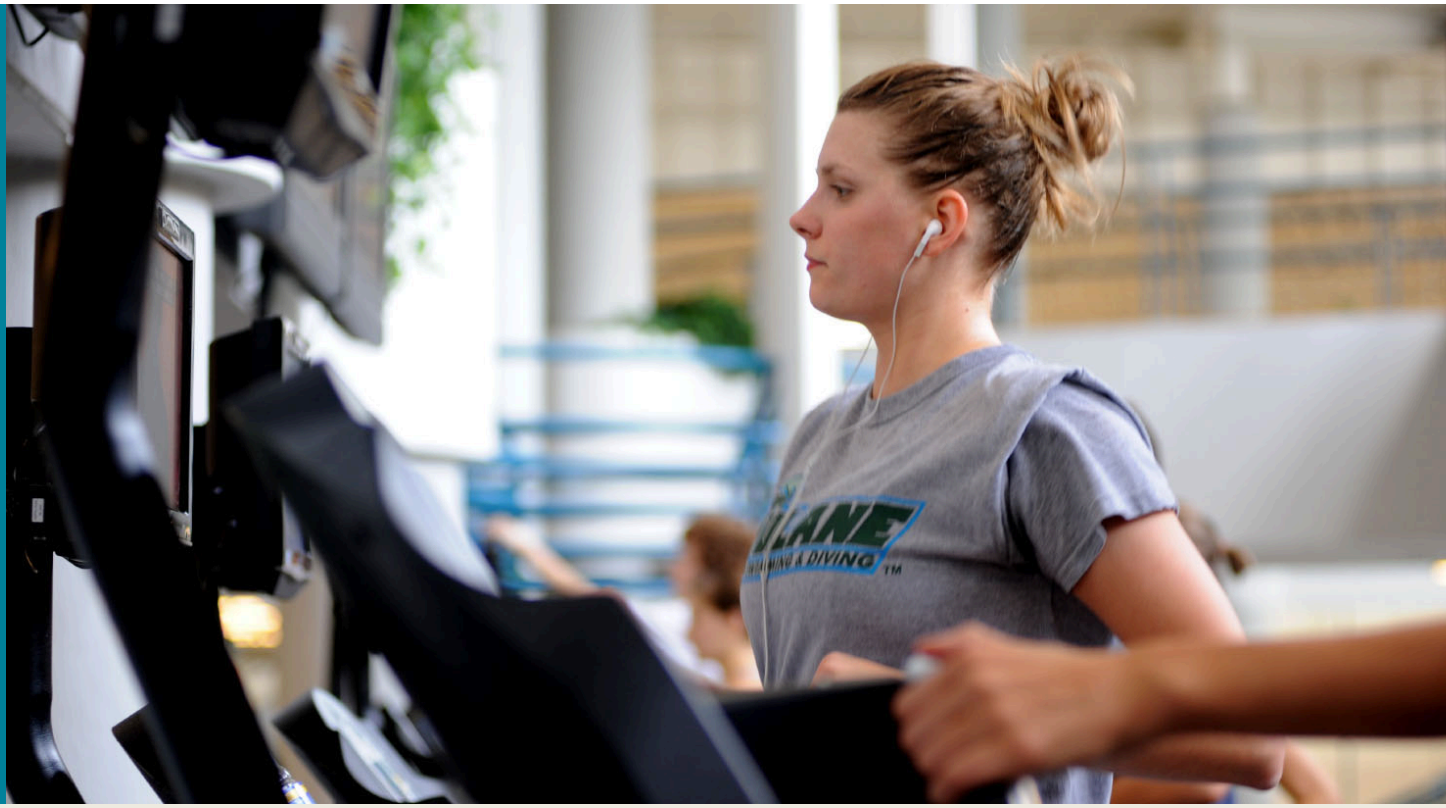

FIGURE 11.1 Vigorous exercise requires a healthy respiratory system. (credit: modification of "Working Out At The Reily Center (3726377407)" by Tulane Public Relations/Wikimedia Commons, CC BY 2.0)

CHAPTER OUTLINE

INTRODUCTION Adequate lung function is an essential bodily function. Both acute and chronic respiratory conditions can impact the body's ability to achieve effective gas exchange. When changes occur due to illness or injury, the body works hard to compensate. Despite the body's efforts to achieve effective gas exchange when damage has occurred, problematic symptoms may require urgent intervention to prevent life-threatening complications. Understanding oxygenation, perfusion, and common disorders of the respiratory system is essential for providing effective nursing care for patients with respiratory issues. Nursing assessment of the upper and lower

airways provides an opportunity for close monitoring of potential and active respiratory problems.

11.1 Concepts of Oxygenation and Perfusion

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the functions of respiratory anatomy and physiology
- Define the concepts of oxygenation and ventilation
- Discuss the relationship of respiratory physiology on oxygenation and ventilation
- Define the concept of perfusion
- Discuss the relationship of respiratory physiology on perfusion

An adequately functioning respiratory system is vital to survival. Each breath provides an opportunity for the body to receive oxygen, remove carbon dioxide, and help maintain acid-base balance. A functioning respiratory system has adequate airflow in and out of the lungs, provides oxygen to fuel the body's tissues, and allows sufficient clearance of carbon dioxide during exhalation. Nonessential tasks of the respiratory system include sensing odors and speech production. Because of the vital functions of the respiratory system, protection is necessary. The ribs, as well as protective membranes, safeguard the lungs from injury. The body also has multiple defenses to prevent pathogens from entering the respiratory tract, such as mucus and nasal mucosa.

Respiratory Anatomy and Physiology Review

The respiratory system allows the body to breathe in air, eliminate carbon dioxide, and oxygenate blood. It is made up of two zones: the conducting zone and the respiratory zone. The **conducting zone** includes all parts that help deliver air to the lower airway for ventilation and perfusion. These areas serve as passageways for air to flow into and out of the lungs. The **respiratory zone** describes the parts that perform gas exchange. These are the areas where oxygen from the outside air enters the bloodstream and is swapped for carbon dioxide.

The major structures of the respiratory system are shown in Figure 11.2.

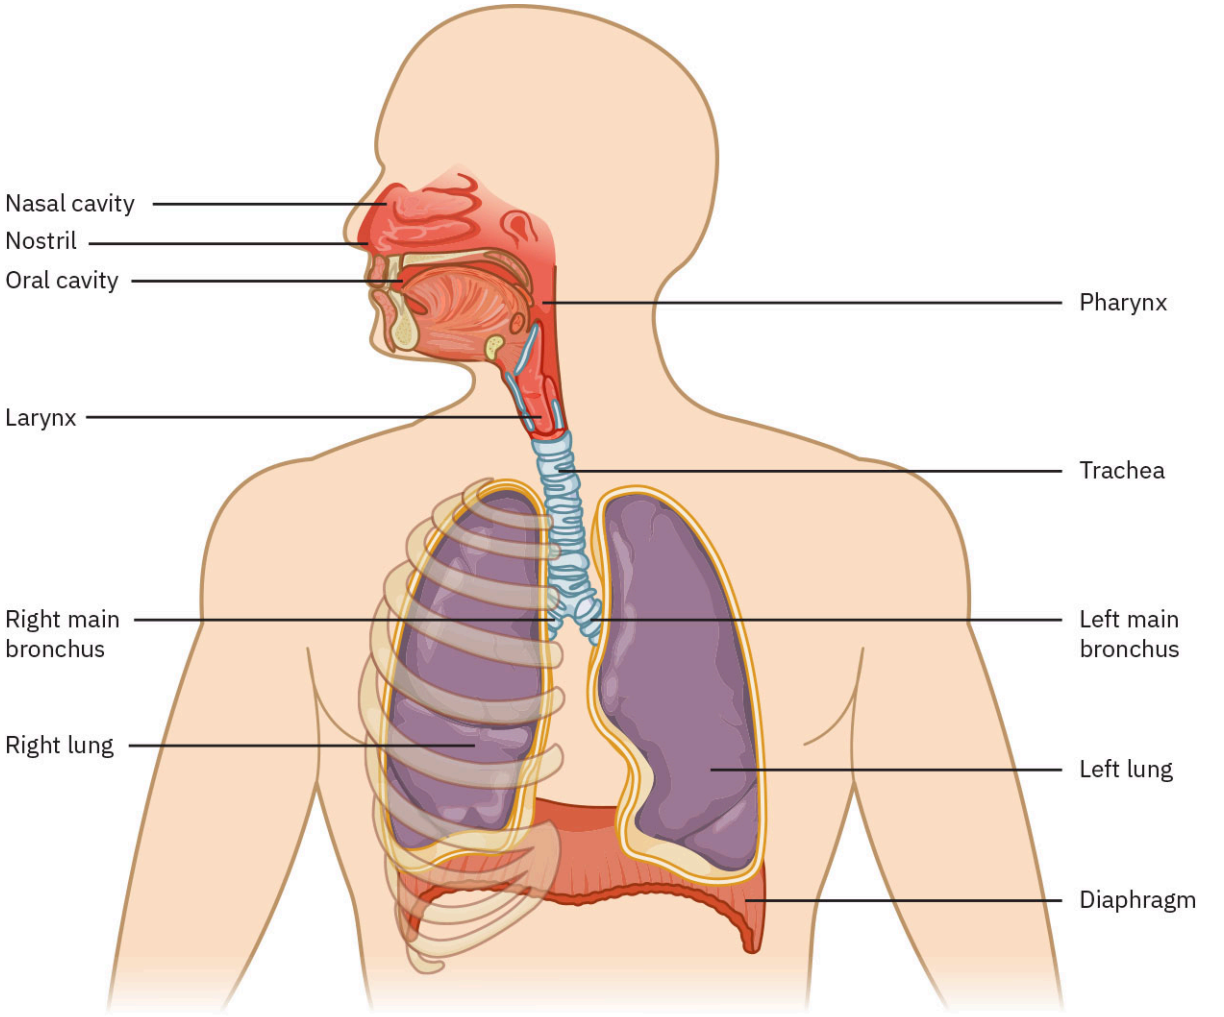

FIGURE 11.2 The respiratory system consists of the conducting zone, which is represented by the trachea, larynx, pharynx, nostril/nasal cavity, and oral cavity. The bronchus, left lung, right lung, and diaphragm deliver air to the lower airway and the respiratory zone, where gas exchange occurs. LINK TO LEARNING

Watch this Crash Course on the respiratory system (https://openstax.org/r/77RespSystem) that reviews respiratory anatomy and physiology.

Components of the Conducting Zone

The conducting zone starts at the nose and mouth, where air enters and exits the body. The primary purposes of this zone are to humidify and warm air and to minimize the likelihood of pathogens and debris entering the body. The nasal passages and paranasal sinuses are lined with respiratory epithelium. Respiratory epithelium generates mucus, which helps to catch and trap debris. The cilia of respiratory epithelium are short, hairlike structures that move continuously, sweeping mucus and debris toward the throat so it can be swallowed instead of advancing into the lower respiratory tract. Because the epithelium is moist, it adds humidification to air as it enters the body. Capillaries under the epithelium are a source of warmth. When inhaled air is warmed and humidified, it is less likely to damage delicate tissues in the lungs. Some cells in this area provide protection by secreting antibacterial enzymes and proteins. Protective immune cells exist in the connective tissue underneath the respiratory epithelium.

The **pharynx** is a muscular tube with an inner mucous membrane lining; it connects the nasal passages and oral cavity to the trachea and esophagus (Figure 11.3). Its three regions are the nasopharynx, oropharynx, and

laryngopharynx. The **nasopharynx** allows air to pass from the nasal cavity toward the trachea. The **oropharynx** allows passage of both air and food. The **laryngopharynx** is the most inferior portion of the pharynx. It is located superior to both the trachea and esophagus. Like the oropharynx, it allows passage of both air and food. The upper portion of the laryngopharynx is lined with epithelial cells capable of secreting mucus, which helps to trap pathogens and debris. Additionally, cilia beat continuously, sweeping mucus and debris upward so it can be swallowed instead of remaining in the respiratory tract.

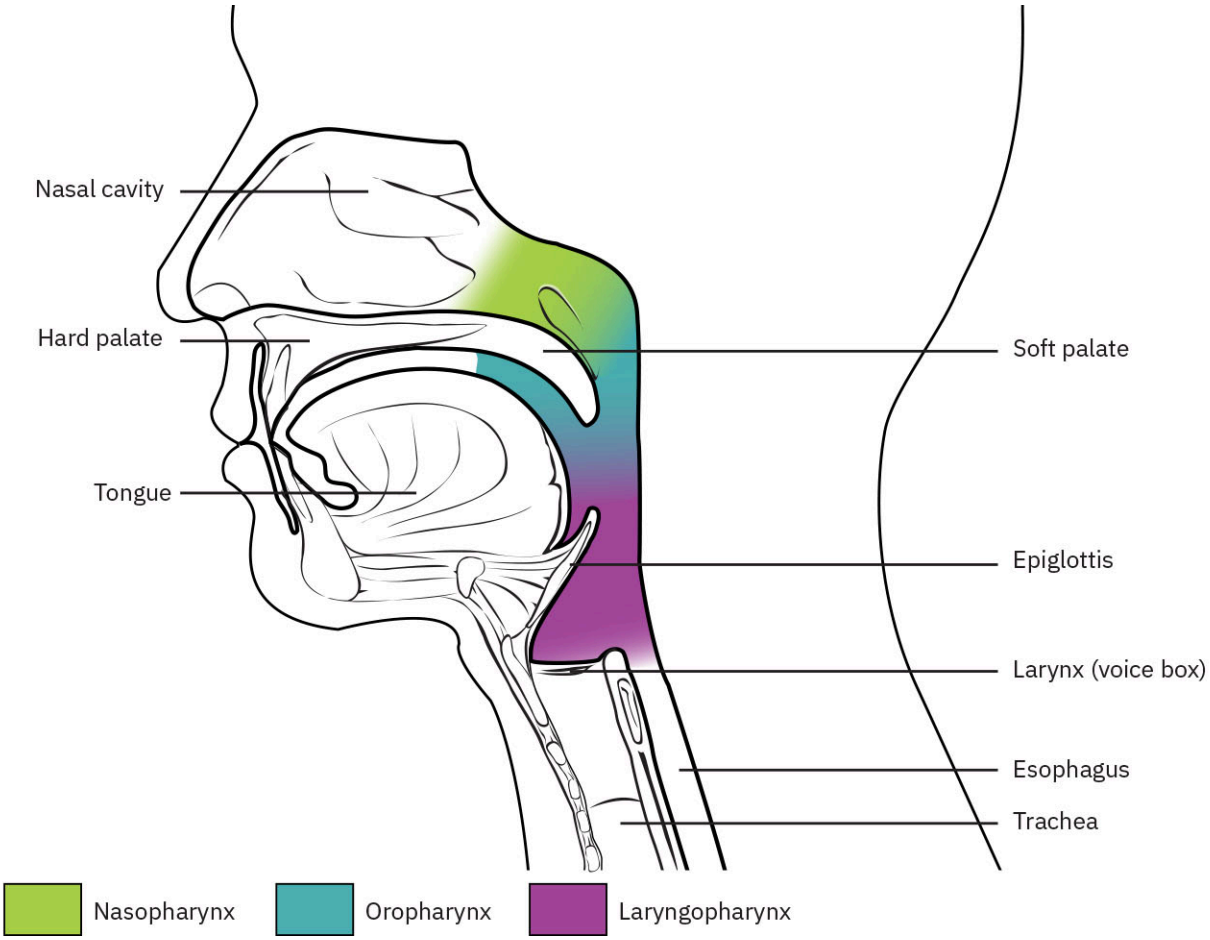

FIGURE 11.3 The pharynx is divided into three regions: the nasopharynx, the oropharynx, and the laryngopharynx. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The **larynx** is made of cartilage and joins the pharynx to the trachea (Figure 11.4). It regulates how much air goes into and out of the lungs. The thyroid cartilage, epiglottis, and cricoid cartilage are the key structures in the larynx. The laryngeal structures protect the opening of the trachea during swallowing and allow vibrations in the vocal cords to produce sound.

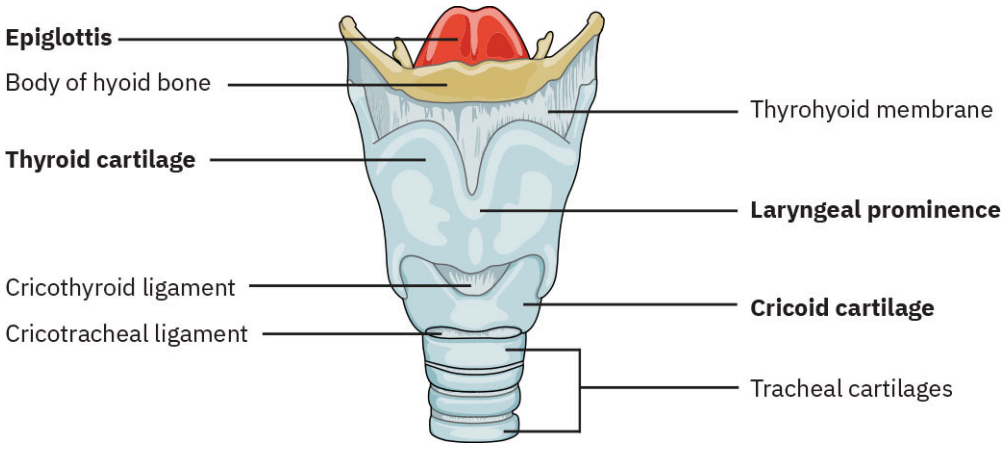

FIGURE 11.4 The larynx extends from the laryngopharynx and the hyoid bone to the trachea. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The **trachea** is anterior to the esophagus and extends downward from the larynx to the lungs (Figure 11.5). This tube is made up of sixteen to twenty C-shaped pieces of hyaline cartilage, joined by connective tissue. The cartilage rings provide rigid support and keep the trachea open. A fibroelastic membrane encases the posterior trachea. The fibroelastic membrane provides flexibility to permit the trachea to shift and stretch slightly during breathing. The trachea is lined with epithelial cells that secrete mucus and beat consistently to sweep debris up and out of the airway.

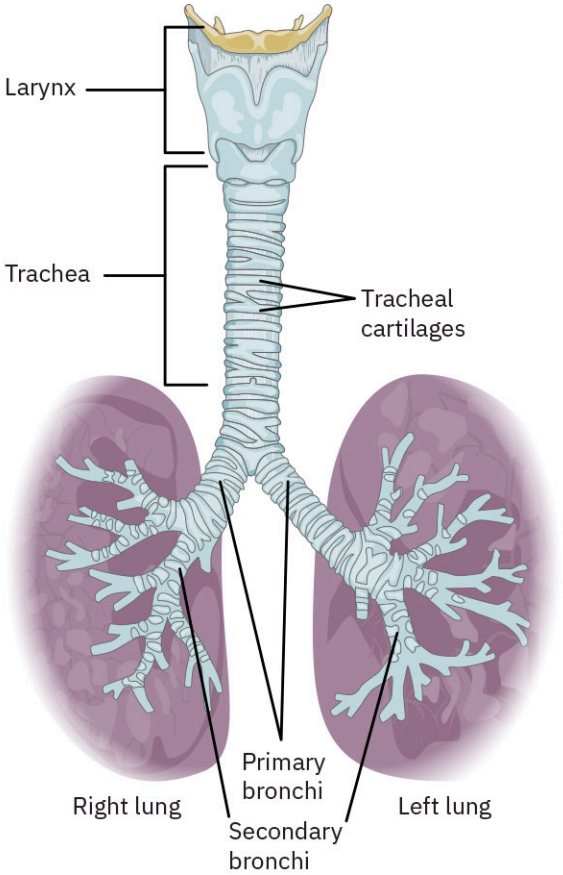

FIGURE 11.5 The tracheal tube is formed by stacked, C-shaped pieces of hyaline cartilage. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The **carina** is the point where the trachea splits into the right and left primary bronchi. Specialized nervous tissue in the carina can detect foreign bodies (such as food) and will cause forceful coughing to expel it. The bronchi are lined with epithelial cells capable of producing mucus. Each primary bronchi enters the lung and continues to split into a bronchial tree. The bronchi serve as a passage for air to enter and exit the lung. The bronchi continue to branch into

smaller and smaller airways called bronchioles. Bronchioles have muscular walls that can flex to increase or decrease airflow. With a diameter of approximately one millimeter, these tiny airways continue branching off until they end in small terminal bronchioles. Terminal bronchioles lead to the site where gas exchange occurs.

The lungs connect to the trachea via the right and left bronchi (Figure 11.6). The diaphragm is adjacent and inferior to the lungs. To accommodate space for the heart, the left lung is smaller than the right lung. The left lung has two lobes, and the right lung has three lobes. The ribs and sternum provide protection for the lungs and heart. The lungs are encased in protective membranes called **pleurae**. The parietal pleura is the outer layer, and the visceral pleura is the inner layer. The pleural space is the small area between the parietal and visceral pleura.

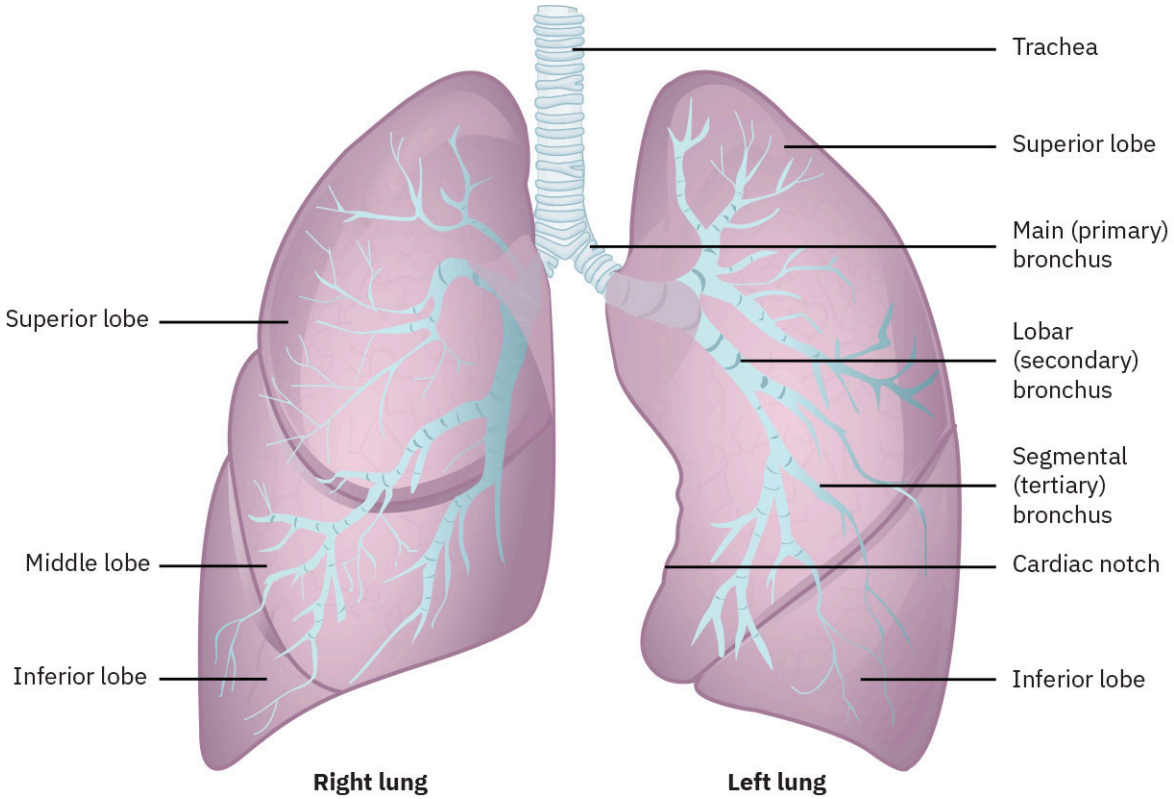

FIGURE 11.6 Each lung is composed of smaller units called lobes. Fissures separate these lobes from each other. The right lung consists of three lobes: the superior, middle, and inferior lobes. The left lung consists of two lobes: the superior and inferior lobes. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

A small volume of pleural fluid provides lubrication and creates surface tension to keep the lungs expanded. Most of the pressure changes that drive inspiration and expiration are caused by movement in the intercostal muscles and diaphragm.

The **medulla oblongata** in the brain is the respiratory center and controls breathing by responding to shifts in carbon dioxide, oxygen, and blood pH (potential hydrogen). When changes in the pH of cerebrospinal fluid (CSF) are detected in the medulla oblongata, it can change the respiratory rate so that pH shifts back into the normal range. Autonomic functions control the rate and depth of respiration based on the chemical changes discussed preceedingly.

Components of the Respiratory Zone

The respiratory zone begins where terminal bronchioles meet a respiratory bronchiole (Figure 11.7). This connects to an alveolar duct and opens into a cluster of alveoli. An **alveolus** is an individual, grapelike sac in the lungs where gas exchange occurs, and an **alveolar sac** is a group of alveoli. Alveoli are elastic and stretch during inspiration, increasing the available surface area for gas exchange.

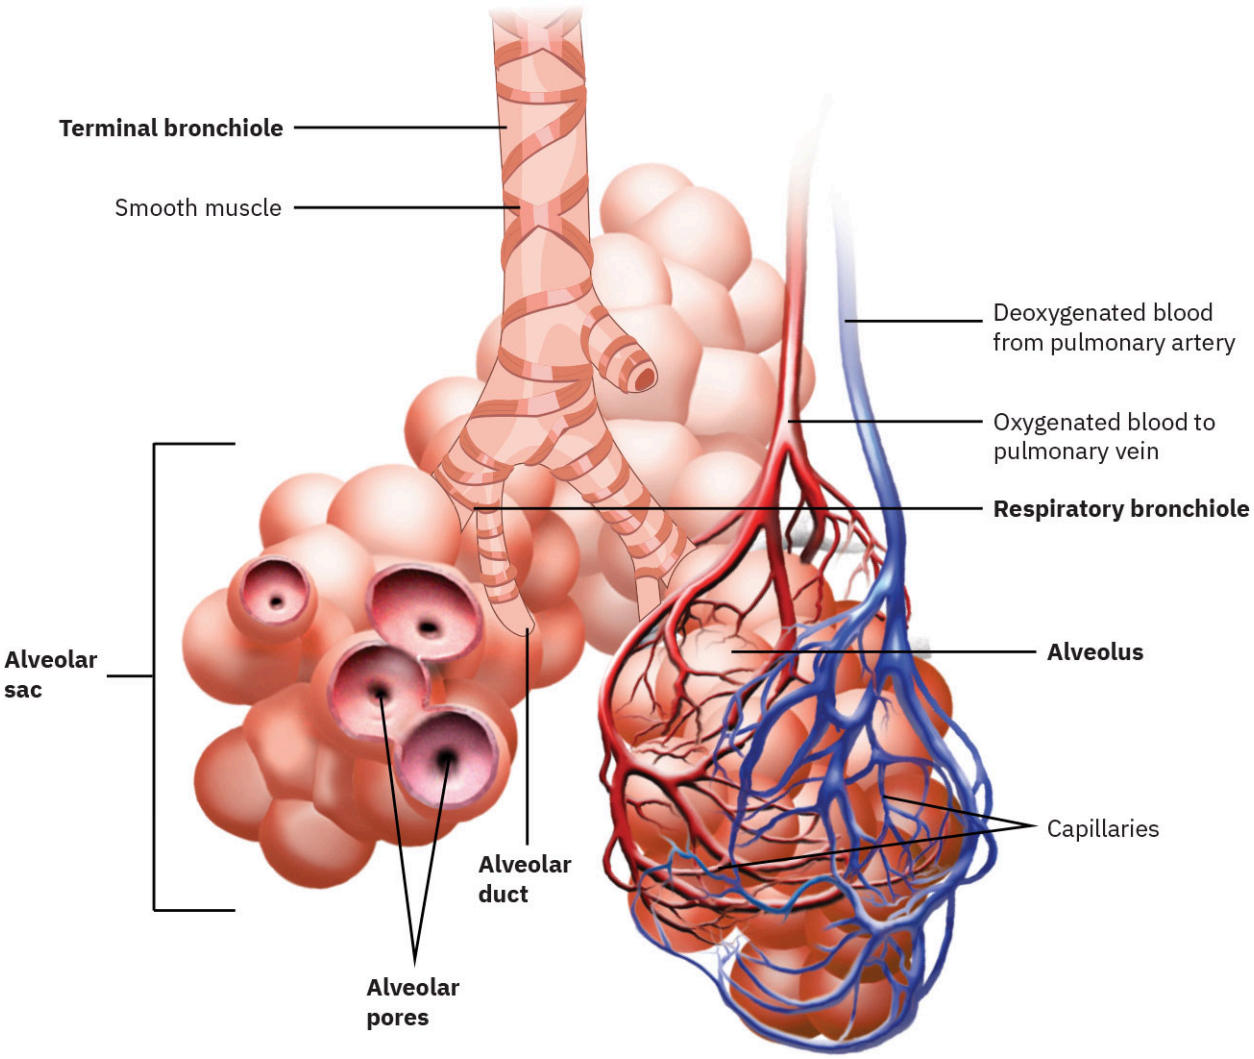

FIGURE 11.7 Bronchioles lead to alveolar sacs in the respiratory zone, where gas exchange occurs. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

LINK TO LEARNING

Watch this Crash Course on the respiratory system (https://openstax.org/r/77Respiratory) that reviews diffusion, the mechanics of breathing, and gas exchange.

Oxygenation and Ventilation

The movement of air into and out of the lungs, which allows gas exchange to occur, is called **ventilation**. Air flows from an area of high pressure to an area of low pressure. During inhalation, air passes through the conducting zone and travels to the respiratory bronchiole and the alveolar sacs.

The process when oxygen from the air moves into the bloodstream is called **oxygenation**. When air enters the lungs and travels to the alveoli, oxygen molecules pass into the capillaries by **diffusion**, which is the movement of substances from an area of high concentration to an area of low concentration (Figure 11.8). The term **partial pressure** refers to how much of a gas is dissolved in the blood. Because there is a higher partial pressure of oxygen in the alveoli than the capillaries, the pressure gradient pulls oxygen into the bloodstream. Carbon dioxide in the blood diffuses across the capillaries into the alveoli, where it leaves the body during exhalation.

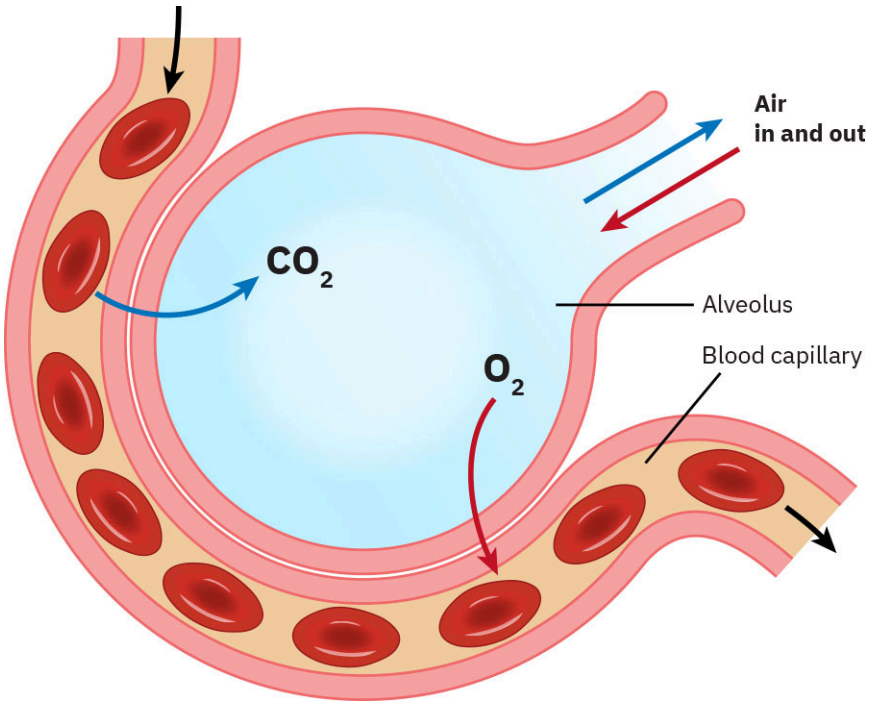

FIGURE 11.8 When air enters the lungs and travels to the alveoli, oxygen molecules pass into the capillaries by diffusion. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Because oxygen does not dissolve well in liquids, it uses red blood cells as a means of transportation. Oxygen molecules attach to hemoglobin in the red blood cells. When oxygen binds to hemoglobin, a chemical reaction occurs, and **oxyhemoglobin** is formed. Oxyhemoglobin is a bright red molecule and contributes to the vivid red color observed in arterial blood. Once oxygen is in the blood, it can travel through the body and be transferred to the tissues.

View a real-time MRI of the thorax (https://openstax.org/r/77ThoraxMRI) during breathing. Note how the diaphragm lowers and the ribs expand during inspiration. Note how the diaphragm raises and the ribs contract during expiration.

Factors That Affect Oxygenation and Ventilation

Many factors affect oxygenation and ventilation (Table 11.1). Any condition that creates a decreased respiratory rate or limitation of chest wall/diaphragmatic expansion can create a decrease in oxygenation either through hypoventilation or other factors. Narrowed airways, found in conditions such as asthma or **angioedema** (soft tissue swelling in the deep layers of the skin, most commonly in the mouth, eyelids, and genitals), can limit airflow into the body, decreasing the amount of oxygen the lungs can utilize. In conditions, such as anemia or hemorrhage, a decreased volume of red blood cells reduces hemoglobin levels and limits the body's oxygen-carrying capability. Damaged alveoli and pulmonary capillaries can occur in lung diseases, such as chronic obstructive pulmonary disease (COPD), decreasing the areas that are available for ventilation and causing inadequate oxygenation. In atelectasis as well as pneumonia, some alveoli are unventilated, leaving fewer capillaries available for gas exchange. Alveolar filling disorders, such as hemorrhage, affect ventilation and oxygenation due to a decrease in available areas of gas exchange (Theodore, 2022).

Condition	Effect
Asthma or angioedema	Narrowed airways can limit airflow into the body, decreasing the amount of oxygen the lungs can utilize.
COPD	Damage to alveoli and pulmonary capillaries can decrease the areas that are available for ventilation and cause inadequate oxygenation.
Atelectasis and pneumonia	Some alveoli are unventilated, leaving fewer capillaries available for gas exchange.
Alveolar filling disorders (e.g., hemorrhage)	Ventilation and oxygenation are affected due to a decrease in available areas of gas exchange.
Anemia or hemorrhage	A decreased volume of red blood cells reduces hemoglobin levels and limits the body's oxygen-carrying capability.
Perfusion defects, such as pulmonary embolus or blood clot	The oxygen-carbon dioxide exchange can be impaired.

TABLE 11.1 Factors Affecting Oxygenation and Ventilation

Perfusion

While the term **perfusion** is used to describe blood flow throughout all parts of the body, certain concepts specifically relate to perfusion of the respiratory system. Perfusion occurs when blood flows through the pulmonary capillaries. This flow allows:

- deoxygenated blood to flow toward the alveoli to receive oxygen by way of diffusion
- oxygenated blood to flow into the pulmonary vein and enter the left side of the heart, to be pumped out through the circulatory system

Factors That Affect Perfusion

Factors that affect blood flow through the blood vessels of the lungs affect perfusion. When blood vessels are blocked or narrowed, it decreases the lung's ability to oxygenate blood. When areas of the lung are inadequately ventilated, more problems occur. Capillaries become constricted and blood flow is diverted to alveoli that are sufficiently ventilated. Conversely, in alveoli that are adequately ventilated, the diameter of the pulmonary arterioles increases in response to a greater partial pressure of oxygen in the alveoli. The increased diameter allows greater blood flow through these functioning parts of the lung.

11.2 Upper and Lower Respiratory Assessment

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the components of an upper respiratory airway assessment
- Describe the components of a lower respiratory airway assessment
- Summarize the cues to recognize and analyze in both upper and lower airway assessment

Respiratory assessment is important for all patients, even in the absence of known respiratory problems. Initial assessment looks at the patient's overall appearance, observing for pallor, cyanosis, or sweating. Vital signs are evaluated and help reflect the efficiency of the respiratory system by monitoring the respiratory rate and oxygen saturation. Changes in respiratory rate, capnography, and level of respiratory effort can be early signs of other systemic problems, whereas drops in oxygen saturation may be later signs of systemic problems. This section will explore the assessment of the upper and lower respiratory airway system.

Subjective assessment involves focused questions to elicit information about a patient's current symptoms and concerns, including:

- Have you ever been diagnosed with a respiratory condition, such as asthma, COPD, pneumonia, or allergies?
- Are you short of breath with activity?
- Does shortness of breath or difficulty breathing interfere with your ability to perform activities of daily living?
- Do you use supplemental oxygen?
- Do you use home respiratory equipment like CPAP (continuous positive airway pressure), BiPAP (bilevel positive airway pressure), nebulizer devices, or a ventilator?
- Are you currently taking any medications, herbs, or supplements for respiratory concerns?
- Have you noticed any changes with your breathing?
- Have you had any feelings of breathlessness (dyspnea)?
- Do you have a cough?
- Do you smoke or vape?

Upper Respiratory Airway Assessment

An upper respiratory airway assessment builds on the initial results of vital signs and level of consciousness. Determine the patient's respiratory rate. Then, consider if the patient's breathing pattern is regular or irregular and observe the approximate duration of inspiration compared with expiration. Note the level of effort and observe for accessory muscle usage. Before using a stethoscope, note if the patient's breathing is audible, and identify the characteristics of any sounds that are present.

Observe the patient's position to obtain important cues about their respiratory status. A patient may breathe easily in any position, or they may struggle more when they are not upright. Similarly, the patient's activity level and ability to speak offers significant information. One patient may be able to walk and exert themself with no significant change in respiratory effort. Another patient may experience visible breathlessness when trying to speak and have limitations on their activity level.

Observe the patient's nose and mouth. Assess for the presence of mucus, drainage, bleeding, and any signs of trauma. Inspection of the patient's oral cavity looks at dental status and evaluates the gums and tongue for swelling, color, moisture level, and open areas. Assess for the presence of a cough. Important information to note includes frequency, severity, sound, and any production of sputum or blood.

Evaluate the patient's chest for symmetry and shape. The trachea should be midline; clavicles should be symmetrical. Chest wall movement during inspiration and expiration should be equal. Compare the anterior-posterior diameter of the chest to the transverse diameter (Figure 11.9). A ratio of 1:2, where the front-to-back distance is about half of the side-to-side distance, is expected. Palpate the patient's chest to look for injuries, swelling, masses, and pain. Palpation can also identify the presence of any sensation or sounds associated with air trapped in the tissues. Listen for any **adventitious lung sounds**, which are breath sounds other than a clear sound of air.

UNFOLDING CASE STUDY

COVID Complications: Part 1

The nurse is assessing a sixty-two-year-old man who presents to the ED and reports he has had increasing difficulty in breathing and shortness of breath the past four days. The patient is accompanied by his wife. The patient states he was exposed to COVID one week ago.

PMH	Patient is recently retired from working as a manager in a health-care facility. He has diabetes managed with oral hyperglycemic agents, CABG ten years ago with two coronary artery grafts, and developed community acquired pneumonia. He has HTN controlled with medication. The patient has received his pneumococcal, influenza, and COVID vaccine six months ago. **Family History** Father has a history of a heart attack, tobacco use, HTN, DM, and passed away at age sixty. Mother died of breast cancer at age fifty-eight. He has three grown children who all live out of town. One brother died of a heart attack ten years ago. **Social History** Patient lives at home with wife. Past history of tobacco abuse and quit four years ago. He states he has three to four drinks/week socially. Patient states he retired early due to stress at work. **Current Medication** Atorvastatin 40 mg once daily Losartan 100 mg twice daily, takes in the a.m. Carvedilol 50 mg twice a day Baby ASA once daily Liraglutide 10 mg daily Acetaminophen 500mg 2 tabs for temperature > 100.7 No Known Allergies
Nursing Notes	**1930: Triage Assessment** Patient presents with dyspnea and shortness of breath (SOB), which increases when talking, and a dry, nonproductive cough. Patient's O_2 saturation is 90 percent on room air. Patient has elevated BP, HR, and RR. Skin is warm and dry to the touch. Patient is slightly restless and anxious and reports fatigue. He is asking if he has COVID. He does not want to be admitted to the hospital but is cooperative. He is alert and oriented to person, place, and time. Lung sounds with bilateral diminished breath sounds and scattered crackles in bilateral bases. He is restless and fidgety. He tries to sit at edge of cart, moving self frequently. Patient reports he "just retired." He did not take his medications yet today. The provider orders his usual meds and nurse administers.

Flow Chart	**1930: Triage Assessment** Blood pressure: 170/92 Heart rate: 110 Respiratory rate: 30 Temperature: 101.2 Oxygen saturation: 90% room air Pain: no pain Weight: 190 lbs Height: 5 ft. 9 in **02/20/23, 00:00** **Physical Examination** HEENT: Pupils equal and reactive to light, mucous membranes dry, no thyroid enlargement. Lymphatic: Lymphatic nodes were not swollen or enlarged Respiratory: Increased agitation, increased vital signs, increasing effort to breathe. Lung sounds with diminished bases and mid lung field, with increasing crackles from baseline. Dry nonproductive cough. Cardiovascular: Tachycardia, repeat ABG demonstrating respiratory acidosis with lower pH, decreased PO_2, and increased PCO_2 from baseline. Abdomen: Soft, denies pain by nodding no, not distended, bowel sounds present all four quadrants Musculoskeletal: Weak, bodily fidgeting has decreased. Not following all commands to move extremities. Skin: Pale, moist **Mental Assessment** Increased agitation and onset of confusion.

Flow Chart	**2/20/24, 0:00** Blood pressure, 182/92 Heart rate, 108 Respiratory rate, 30 Temperature, 101.1 Oxygen saturation, 90% room air Pain, denies pain **02/20/2024, 04:00 Assessment** Blood pressure, 150/88 Heart rate, 100 Respiratory rate, 30 Temperature, 101.0 Oxygen saturation, 88% room air Pain, denies pain ABG: pH, 7.31 PCO_2, 55 mmHg PO_2, 60 mmHg HCO_3, 30 mEq/L **2/20/2024, 08:00** Increased agitation, increased vital signs, increasing effort to breathe. Liraglutide 10 mg daily First set of blood cultures drawn Cefazolin 1.5 mg IV started per order Reassess VS: B/P, HR, RR, temperature, O_2 saturation Albuterol nebulizer X1 administer by respiratory therapy Acetaminophen 500 mg 2 tabs for temperature > 100.7

1. After assessing the patient, the nurse determines the patient's presentation is due to [Option 1] resulting in a new symptom of [Option 2]. Choose the most likely options for the information missing from the statement by selecting from the lists of options provided.

Option 1	Option 2
Panic attack	Increased SOB and fever
Medication side effects	Irritability
Asthma	Cough
Respiratory infection	Wheezing
Depression	Respiratory rate 30

2. Once the nurse has reviewed the relevant patient information, which assessment finding(s) are most consistent with the associated disease process?

Assessment Finding	Respiratory Infection	COPD	Pneumothorax
Pain in chest and intense chest pain that is worse with movement			
Temperature: 101.2			
Tracheal deviation			
Subcutaneous emphysema			
Barrel-shaped chest			

Lower Respiratory Airway Assessment

A lower respiratory airway assessment focuses on auscultation of lung sounds during inspiration and expiration. Ideally, lung auscultation is performed with the patient in the upright position. If an injury or serious illness prevents the patient from sitting up, turn them to the side. Using the diaphragm of the stethoscope, systematically move the stethoscope side to side across all lung fields (Figure 11.10); this allows the nurse to compare lung sounds at the same level on both sides.

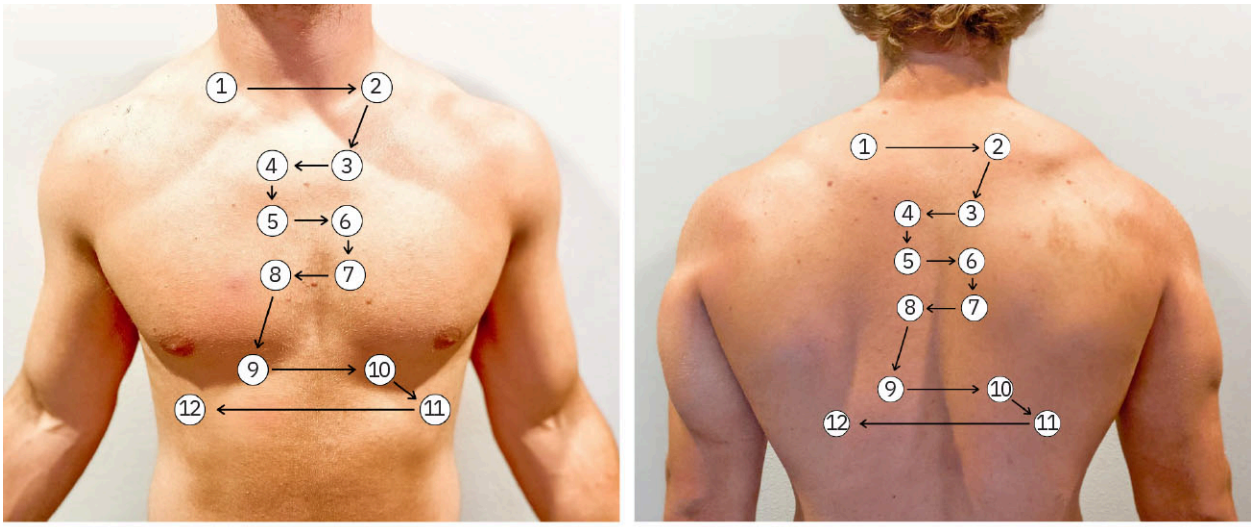

FIGURE 11.10 Anterior and posterior auscultation areas of the lungs should be auscultated following a systematic pattern. (modifications of credit: "Figure 10.5 Anterior Auscultation Areas" and "Figure 10.6 Posterior Auscultation Areas" by Meredith Pomietlo/Chippewa Valley Technical College, CC BY 4.0)

Normal lung sounds vary based on the part of the lung field being auscultated:

- The **bronchial breath sounds** are high-pitched, loud sounds heard over the trachea and larynx.
- The **bronchovesicular breath sounds** are medium-pitched and heard over the major bronchi.
- The **vesicular breath sounds** are lower-pitched sounds heard over the lung surfaces; they are often described as soft, rustling sounds.

Adventitious lung sounds can indicate airway diseases and problems. The presence of mucus or fluids changes the way air flows through the passageways, resulting in abnormal lung sounds. Obstruction, inflammation, and infection can also cause adventitious lung sounds. Examples include the following:

- Popping or crackling sounds heard on inspiration as collapsed airways reopen are called **fine crackles** or **rales**. This occurs with conditions such as heart failure or pneumonia, when fluid accumulates within the alveoli and other lung spaces or when airways collapse. Crackles may be fine or coarse. Fine crackles are soft and higher pitched. Coarse crackles are loud and lower pitched.
- Whistling-type noises produced during expiration (and sometimes inspiration) are called **wheezes**. Wheezes occur when air travels through airways narrowed by constriction or swelling.
- Coarse, loud sounds that occur due to constriction in the larger airways due to mucus or fluid are called **rhonchi**.
- Heard only on inspiration, **stridor** is harsh, high-pitched, and is often loud enough to hear without a stethoscope. Stridor occurs when the upper airway is narrowed, and airflow is obstructed. Stridor is a potentially life-threatening emergency.
- Caused by inflamed lung surfaces rubbing against each other, **rub** has a grating sound.

LINK TO LEARNING

This video gives examples of abnormal breath sounds (https://openstax.org/r/77AbnormBreath) such as crackles, rales, wheezes, rhonchi, and others.

Cues to Recognize and Analyze for Upper and Lower Airway Assessment

A thorough respiratory assessment provides important information that may indicate the patient requires immediate intervention. Even with normal vital signs, respiratory problems can be present. Before using a stethoscope or obtaining vital signs, the nurse first observes for potential signs of distress. Respiratory compromise can present as changes in level of consciousness. Both **hypoxemia** (low blood levels of oxygen) and hypercapnia can cause a

decreased level of consciousness, irritability, anxiousness, restlessness, or confusion.

Subtle changes in the rate of breathing can be a sign of deteriorating condition; accurate assessment of respiratory rate is necessary. Normal breathing is regular and has a rate of twelve to twenty breaths per minute and regular. By contrast, **bradypnea** is less than twelve breaths per minute, and **tachypnea** is greater than twenty breaths per minute. Oxygen saturation is also assessed; the normal range is 94 to 100 percent (SpO2). Increased heart rate and blood pressure can also occur when someone is struggling to breathe.

CLINICAL SAFETY AND PROCEDURES (QSEN)

Safety: The Challenges of Pulse Oximetry Monitoring

Measuring oxygen saturation, or pulse oximetry, is commonly used as a part of a routine assessment. These devices can provide helpful, noninvasive information about blood oxygen saturation. Recent research shows, however, that **pulse oximeter**s can be less accurate in patients with darker skin pigmentation, or even colored fingernail polish, which may overestimate their oxygen saturation when their actual oxygen levels may be less than 80 percent. This inaccuracy can mask hypoxemia and result in lower oxygen supplementation and poor patient outcomes. It is also challenging to measure oxygen saturation of patients with poor perfusion or fluid volume deficit. Because an accurate representation of oxygenation is difficult to obtain, awareness of how this measurement bias can contribute to race-based disparities in care is essential. Ongoing study is needed, especially in the context of models that use data from electronic health records and artificial intelligence to identify and predict outcomes. Patients, clinicians, and manufacturers are all affected parties.

(Feldman & Lane-Fall, 2021

End-tidal carbon dioxide ($EtCO_2$) monitoring, or **capnography**, is a noninvasive way to measure exhaled carbon dioxide and provide information about ventilation. Capnography can alert clinicians to abnormally elevated or decreased carbon dioxide levels that may require intervention. Capnography can detect respiratory depression earlier than pulse oximetry. Commonly used during anesthesia and in settings requiring intubation, it is now gaining favor in other settings. In spontaneously breathing patients, capnography can be helpful in circumstances including:

- assessing for hypoventilation in patients who are unconscious, unresponsive, or receiving sedation
- assessing seizing or critically ill patients
- identifying treatment response during acute respiratory distress
- identifying the efficacy of CPR and the possible return of spontaneous circulation during cardiac resuscitation (Krauss et al., 2022).

During physical assessment with inspection, the nurse notes changes in appearance that can indicate respiratory distress, such as pallor and cyanosis. The patient's position and posture can offer information about respiratory status. Many patients who are struggling to breathe will be unable to tolerate lying flat. They will naturally move their body into a **tripod position**, an upright position with hands braced on knees or a table (Figure 11.11). This position maximizes the space available for the lungs to expand.

FIGURE 11.11 The tripod position eases the work of breathing by optimizing the space available in the thoracic cavity for lung expansion. (credit: "Figure 13.18 Tripod Position" by Nic Ashman/Chippewa Valley Technical College, CC BY 4.0)

The nurse should closely observe the patient's breathing pattern, including the rhythm, effort, and use of accessory muscles. Normal breathing is subtle and can be almost imperceptible. Audible breathing, nasal flaring, and pursed lip breathing are signs of respiratory difficulty; pursed lip breathing increases the amount of carbon dioxide exhaled so that more oxygen can be inhaled. Stridor indicates a narrowed or obstructed upper airway and requires urgent evaluation. Abnormal breathing may be labored, irregular, or unusually shallow or deep. Normally, inspiration is about half as long as expiration; when expiration is prolonged, it can be reflective of lung problems, such as emphysema. Anatomical structures should be symmetrical; if the trachea is not midline, it can be a sign of decreased lung volume (i.e., from a tumor) or fluid accumulation.

A patient with labored breathing may experience shortness of breath with exertion. In patients with serious lung problems, speaking can be difficult due to shortness of breath. The patient may only be able to speak in short sentences, phrases, or single words. In severe cases of respiratory distress, patients may be unable to speak (Reyes et al., 2022). Other indicators of labored breathing can include diaphoresis and accessory muscle usage. Accessory muscles are found in the upper back, neck, abdomen, and between the ribs.

REAL RN STORIES

Nurse: Emily, RN
Years in Practice: One
Clinical Setting: Inpatient medical unit

Geographic Location: Rural Northwest Community Hospital

As a newly licensed RN, Emily was working on an inpatient medical unit. One of Emily's patients was an older person who had been admitted with pneumonia. The doctors did not yet know what type of pneumonia the patient had and were doing more diagnostic studies.

At the start of her shift, Emily entered the patient's room to do a set of vital signs. The patient was alert and able to answer her questions, the patient's temperature was normal, and the patient's blood pressure was a little bit high.

She put the pulse oximeter on the patient's finger and waited. At first, it had no reading! Then, it displayed a reading of 73 percent, but that went away, and the machine read no result. Emily asked the charge nurse to come into the room to help her troubleshoot the equipment.

As the charge nurse entered the room, together they immediately looked at the patient. The charge nurse asked Emily, "Has the patient been breathing like this the whole time?" The charge nurse—who had years of experience—was able to immediately identify labored breathing. Now that Emily looked more closely at the patient and timed the respirations, she realized that the respiratory rate was about thirty breaths per minute, the patient appeared pale and stressed, and intercostal muscle usage was present. The charge nurse immediately placed a non-rebreather mask on the patient and called the medical team. The patient needed to be transferred to the intensive care unit for closer monitoring and to receive more oxygen therapy.

Palpation of the chest can evaluate potential areas of injury or complications related to a procedure. A popping or crackling sensation when the skin is palpated, **crepitus** is a sign of air trapped under the subcutaneous tissues. This can occur when air trapped in the pleural space moves into the subcutaneous tissue and becomes trapped there. Inspect the fingers for **clubbing**, a bulbous enlargement of the tips of the fingers due to chronic hypoxia. It often occurs in chronic respiratory diseases, such as COPD, as well as other conditions that cause chronic low oxygen levels or malabsorption (Figure 11.12).

FIGURE 11.12 Clubbing is a bulbous enlargement of the tips of the fingers due to chronic hypoxia. (modification of "Showing bilateral grade III clubbing with cyanosis of the extremities" by Twayana et al./BMC Research Notes, CC BY 4.0)

Auscultation identifies adventitious lung sounds, including crackles and wheezes. The nurse analyzes the presence of adventitious lung sounds as well as how they may have changed. Adventitious lung sounds can occur in different lung fields and can also change in volume.

11.3 Disorders of the Upper Respiratory System: Bronchiectasis

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss pathophysiology, risk factors, and clinical manifestations for bronchiectasis
- Describe the diagnostics and laboratory values in the disease of bronchiectasis
- Apply nursing concepts and plan associated nursing care for the patient with bronchiectasis
- Evaluate the efficacy of nursing care for the patient with bronchiectasis
- Describe the medical therapies that apply to the care of bronchiectasis

Bronchiectasis is a chronic lung condition that results in widened, damaged airways. In the United States, there are approximately 350,000 to 500,000 adults with bronchiectasis. Increased case rates occur in women, adults over sixty, and patients with a structural lack of access to resources.

Pathophysiology

In **bronchiectasis**, the elastic, supportive structures of the bronchial wall become damaged, and the bronchi abnormally dilate (Figure 11.13). The damage and dilation make it harder to cough up and clear lower airway secretions. When mucus and phlegm remain trapped in the lower airways, bacteria can flourish. Infection and inflammation cause additional damage to the airways and can worsen bronchiectasis. This causes a recurrent cycle of infection, inflammation, and airway damage.

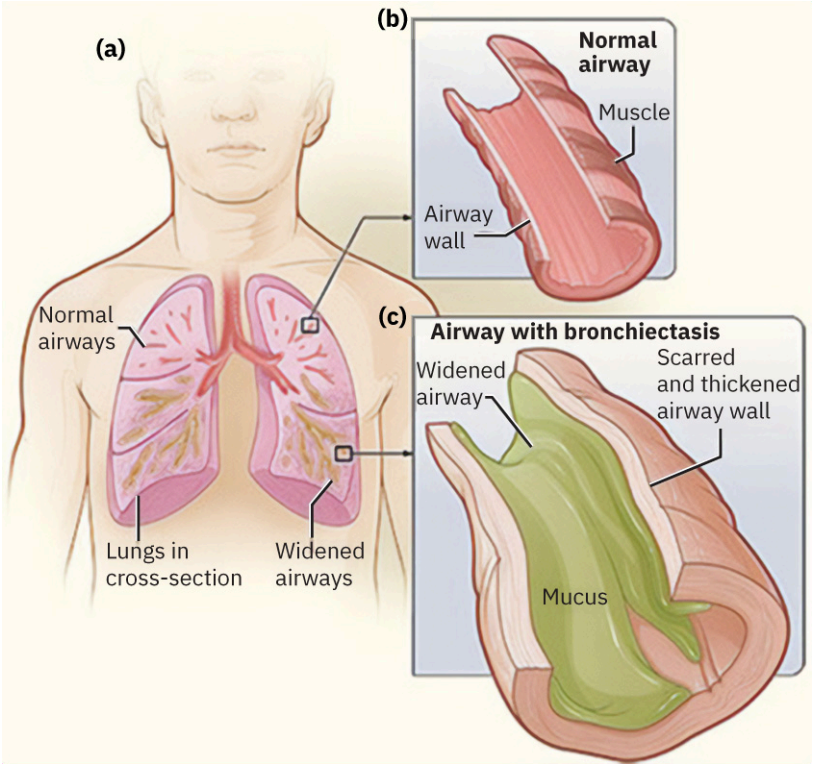

FIGURE 11.13 (a) In this patient's lungs, the upper airways are normal while the lower airways are widened. (b) The normal airway is elastic and retains its shape. (c) The airway with bronchiectasis is wider; sputum can easily become trapped. (credit: "How bronchiectasis affects the lungs." by NIH: National Heart, Lung, and Blood Institute, Public Domain)

Risk Factors

Risk factors for bronchiectasis include genetic diseases that affect the respiratory tract, including cystic fibrosis and primary ciliary dyskinesia. Previous lung infections and immunosuppression can predispose a person to bronchiectasis. Asthma and connective tissue disorders are also associated with a greater incidence of bronchiectasis. The risk of bronchiectasis is increased with airway obstruction; causes of obstruction can include tumor, aspiration, and COPD. Approximately 40 percent of cases are considered **idiopathic**, which means the cause is unknown (American Thoracic Society, 2022). Bronchiectasis is more common in female patients and older adults. In adults sixty and older, bronchiectasis is eight to ten times more prevalent when compared with patients fifty

years old and younger (Barker, 2023c).

Clinical Manifestations

The primary clinical manifestations of bronchiectasis are cough and sputum production. Signs of infection, including fatigue, chills, fever, and night sweats can occur. During an acute infection, the sputum may increase and change color. Patients may report shortness of breath, chest tightness, **hemoptysis** (coughing up blood), and unintentional weight loss (American Thoracic Society, 2022).

Assessment and Diagnostics

Diagnosis of bronchiectasis is made based on the presence of patient-reported symptoms in conjunction with imaging tests. Ninety-eight percent of patients with bronchiectasis will report a cough. Bronchiectasis is suspected in patients who report both a cough and sputum production experienced most days of the week. Because a cough and sputum production can occur with other illnesses, imaging is used to identify anatomical abnormalities that are specific to bronchiectasis. Adventitious lung sounds present in bronchiectasis commonly include crackles, but wheezes may also be present (Barker, 2023c).

To formally diagnose bronchiectasis, imaging is needed. A chest x-ray will commonly show nonspecific abnormalities, such as dilated, thickened airways or **atelectasis**, which is a condition that causes a partial or complete collapse of the lung. A CT scan is needed for definitive diagnosis, however. A CT scan provides evidence of anatomical abnormalities that confirm the diagnosis and identifies which parts of the lungs are affected. Lung function tests, such as spirometry and a six-minute walk, may be used once diagnosis is established. Lung function tests are not used to diagnose bronchiectasis, but to evaluate lung function, disease trajectory, and response to treatment (Barker, 2023c). When infections are present or suspected, additional testing is required. Sputum may be sent for Gram stain and culture; viral testing can evaluate for viruses like flu or COVID-19 (Barker, 2023b).

Nursing Care of the Patient with Bronchiectasis

When providing nursing care to a patient with bronchiectasis, areas of focus include preventing complications and managing symptoms. With comprehensive prevention strategies, modifiable risk factors for developing complications can be addressed, potentially leading to better outcomes.

Recognizing Cues and Analyzing Cues

The nurse providing care to a patient with bronchiectasis recognizes and analyzes subjective and objective assessment data to provide safe care. Subjective data includes shortness of breath, chest pain, and signs of infection, such as chills, feeling warm, and night sweats. Monitor vital signs because of the risk of infection and respiratory compromise. Subtle changes in vital signs, especially respiratory rate, oxygen saturation, and temperature, are especially important to monitor and track. The nurse performs auscultation, noting the location and character of any adventitious lung sounds. A cough will often be present, and the patient should be questioned about its frequency and characteristics. It is important to note the volume and character of any mucus produced, including the presence of visible blood.

Environmental irritants can worsen bronchiectasis. The nurse should ask the patient about exposure to air pollution, smoke, and secondhand smoke. If the patient smokes or vapes, inquire about frequency, years of use, and duration. Because preventable respiratory illnesses can worsen bronchiectasis, inquire about the patient's immunization status.

CLINICAL SAFETY AND PROCEDURES (QSEN)

Teamwork and Collaboration

The care of patients with bronchiectasis can be complex and requires a strong, collaborative, interprofessional team. Medications may be nebulized or inhaled. A nebulizer converts liquid medication into a fine mist. The mist is inhaled through a mask or mouthpiece. A nebulizer is often used to treat those with severe respiratory conditions. An inhaler is a handheld device that delivers a premeasured dose of medication in the form of a spray or powder, and is often used to open the airway passages. Inhalers should be administered prior to nebulizers for optimal absorption of the medications. Respiratory therapists may administer the medication or reinforce teaching with the

nurse, patient, and family. Successful airway clearance strategies may require the cooperation of nursing staff, physical therapists, respiratory therapists, and physicians. Similarly, oxygen administration can require close communication between physicians, nurses, and respiratory therapists to ensure oxygenation goal (usually > 92 percent) is met.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Signs of active infection and inadequate oxygenation are a high priority. When a patient reports symptoms, such as fever and purulent sputum, the nurse should communicate these findings to the provider. Nursing interventions based on a provider order may include administering antipyretics, preparing a patient for CT scan, obtaining a sputum sample for Gram stain and culture, and administering antibiotics. Some patients with bronchiectasis may require supplemental oxygen. The nurse collaborates with respiratory therapy and the provider to identify SpO2 targets and optimize oxygenation. Additionally, the nurse works together with the patient and respiratory therapy on airway clearance strategies, including chest physical therapy, positive expiratory pressure devices, and wearable percussion vests. If a large volume of blood is present in sputum, hemoptysis can be an emergency. Nursing interventions may be related to suctioning and airway clearance, oxygen administration, or preparing the patient for a procedure to stop the bleeding.

Educational topics include immunizations and strategies to avoid environmental irritants. The nurse may provide coaching and resources on smoking cessation. Additional teaching may reinforce how to identify signs of infection and airway clearance strategies and devices.

Evaluation of Nursing Care for the Patient with Bronchiectasis

Evaluate the efficacy of nursing care by assessing the patient's respiratory status. The nurse considers if indicators of infection, adventitious lung sounds, and cough have improved. Consider activity tolerance and oxygen requirement. The absence of vaccine-preventable infections is a goal.

LINK TO LEARNING

Nurses or respiratory therapists will often provide chest physiotherapy (CP) to optimize clearing of the airway. Watch this video for a chest physiotherapy (https://openstax.org/r/77ChestPhysioTx) demonstration.

Medical Therapies and Related Care

Effective treatment of bronchiectasis requires collaboration with the interprofessional team, including physicians, respiratory therapists, and pharmacists. Often, a variety of interventions will be necessary to provide symptom relief and prevent disease progression. In addition to being a potential trigger for the initial development of bronchiectasis, lung infections can also worsen existing cases. Key points for treatment include:

- Treatment with antibiotics is necessary for bacterial infections.
- Antibiotics may be oral, intravenous, inhaled, or nebulized.
- Antiviral medications can be used when a viral infection is present.
- Some patients with recurrent exacerbations may be prescribed a preventive antibiotic.
- Some types of fungal infections cause inflammation that can lead to bronchiectasis; in these cases, antifungal medications and steroids are prescribed.
- A key component of nonpharmacologic therapy for bronchiectasis is avoiding substances that irritate the respiratory tract. Patients are instructed on smoking cessation (including vaping) and to avoid other irritants like cleaning products, dust, and smoke. Some patients may be advised to wear masks to avoid environmental triggers.
- Airway clearance interventions can improve a patient's ability to clear mucus. These include **chest physical therapy**, which can improve drainage and mobilization of mucus; **positive expiratory pressure devices**, which let the patient breathe in easily but create resistance as they exhale, slowing down the breath and causing the patient to increase the force of exhalation; and wearable chest wall high frequency oscillation vests, which provide movement and percussion that helps mobilize secretions.
- Nebulized hypertonic saline is used to thin mucus.

- When immunodeficiencies are present, treatment with immune globulin may prevent bronchiectasis or delay disease progression. An **immune globulin** is a product that may be administered intravenously or subcutaneously to provide necessary antibodies to strengthen the immune system.
- Treating dysphagia or reflux that causes aspiration pneumonia can limit disease progression.
- In patients with major hemoptysis related to severe lung damage, procedures to stop the bleeding may be necessary.
- In advanced cases, surgical removal of the damaged section of lung can be performed.
- Lung transplantation is sometimes necessary (Barker, 2023b).

Treatment is often complex, challenging, and prolonged. Coordinated care that encompasses psychosocial support is essential.

LINK TO LEARNING

The nurse or respiratory therapist will incorporate positive expiratory devices to encourage an increase in the force of expiration to assist with clearing mucus from the airway. Watch this video for a demonstration of a positive expiratory pressure device (https://openstax.org/r/77ExPressDevice) in use.

11.4 Disorders of the Lower Respiratory System: Asthma

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for asthma
- Describe the diagnostics and laboratory values in the disease of asthma
- Apply nursing concepts and plan associated nursing care for the patient with asthma
- Evaluate the efficacy of nursing care for the patient with asthma
- Describe the medical therapies that apply to the care of asthma

Asthma is one of the most prevalent conditions in the United States. Nationwide, about one in every thirteen people has asthma. About 4.8 million children and about 21 million adults have asthma. In children, asthma is more common in males. In adults, asthma is more common in females.

Pathophysiology

Asthma primarily affects the trachea and bronchi. Normally, lungs can easily expand and contract with inspiration and expiration. In asthma, inflammation narrows the airway, making it harder for the lungs to expand, causing an **asthma attack** (Figure 11.14). An asthma attack is also known as asthma exacerbation. Asthma exacerbations have an early phase and a late phase. In the early phase, triggers, such as exercise, cold air, hormonal fluctuations, allergens, and fumes, cause antibodies to be released. These antibodies bind to mast cells and basophils within the lining of the respiratory tract. Mast cells release leukotrienes, histamine, and prostaglandins. These substances cause **bronchoconstriction**, meaning the smooth muscle in the airways constrict, narrowing the airway.

In the late phase, white blood cells, including basophils, eosinophils, neutrophils, and helper and memory T-cells, flow to the lungs. Inflammation, further bronchoconstriction, and increased mucous production occur. Airflow becomes obstructed because of inflammation and airway constriction, causing increased respiratory effort. In a patient with asthma, the airways are considered hyperresponsive, indicating they narrow more than usual in response to stimuli (Sinyor & Perez, 2022).

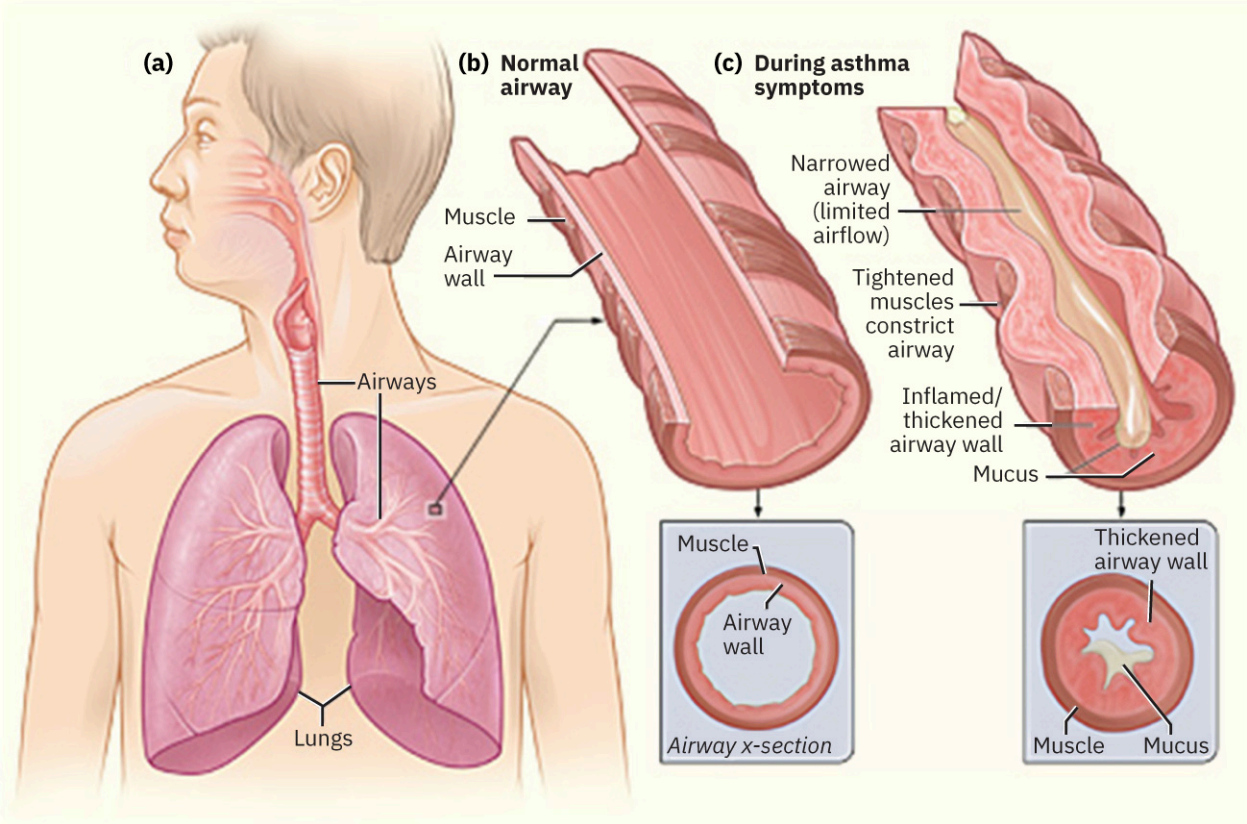

FIGURE 11.14 Lungs with asthma differ from normal lungs. Tight muscles, swollen airways, and mucus are present. As a result, moving air in and out can become difficult. (credit: "Asthma attack-illustration NIH" by United States-National Institute of Health: National Heart, Lung, Blood Institute/Wikimedia Commons, Public Domain)

LINK TO LEARNING

Watch this video about asthma pathophysiology (https://openstax.org/r/77AsthmaPhysTx) to learn more.

Risk Factors

In the United States, 13.5 percent of people have been diagnosed with asthma, and females have a 12 percent higher prevalence of an asthma diagnosis than males (American Lung Association, 2024). Additional risk factors for developing asthma include a family history, prematurity, maternal smoking during pregnancy, and obesity. Many factors both increase the risk of asthma and can trigger an asthma attack. These include allergies, allergic conditions like eczema, viral respiratory infections, cigarette smoking, air pollution, and exposure to substances including dust, fumes, mold, and vapor (Morales et al., 2021).

There are significant racial and ethnic disparities that affect how likely a person is to experience exacerbations, illness, and death related to asthma. Structural factors include systemic racism, lack of access to adequate care, economic disparities, and the physical environment. These factors create inequitable risk that disproportionately affect patients with fewer financial resources, older adults, and Black, Hispanic, and American Indian/Alaska Native populations. Black Americans are nearly three times more likely than White Americans to die from asthma. Overall, Black females have the highest risk of death related to asthma. Compared with White men, Black women have more than triple the risk of dying of asthma. In 2021, 3,517 people died due to asthma. Notably, nearly all asthma deaths are preventable when there is access to adequate resources (Asthma and Allergy Foundation of America, 2023).

Clinical Manifestations

Asthma has four defined stages based on severity: intermittent, mild, moderate, and severe (Table 11.2). Regardless of stage, patients with asthma usually report difficulty breathing, wheezing, and a cough. Often, the cough is worse at night. Symptoms are commonly in response to a trigger, such as exercise or allergens. In severe exacerbations,

respiratory rate and heart rate increase, and patients may sit upright to lean forward into tripod position to facilitate easier breathing.

Stage of Asthma	Symptom Frequency	Nighttime Awakenings Due to Symptoms
Intermittent	< 2 days per week	< 2 times per month
Mild	> 2 days a week but not daily	3 to 4 times a month
Moderate	Daily	> than once a week but not nightly
Severe	Daily + throughout the day	Often > 7 times per week

TABLE 11.2 **Stages of Asthma**

Assessment and Diagnostics

Asthma symptoms may shift over time. Accurate assessment is crucial during initial diagnosis and to prevent complications. Diagnostic tests can provide information about disease severity.

Asthma is diagnosed based on patient history combined with pulmonary function testing. History includes at least one or two, though sometimes all, of the following symptoms in response to a trigger (e.g., allergen, cold air, exercise, infection):

- shortness of breath
- cough that is often worse at night
- wheezing
- chest tightness

Because these symptoms can occur with many respiratory illnesses, additional information is necessary to diagnose asthma. Asthma symptoms typically wax and wane over a period of hours to days and commonly occur in response to a trigger, such as cold air or exercise. Asthma is more common in patients with a family history of asthma and allergies. A person's personal history of asthma-like symptoms as a child, with or without a formal diagnosis of asthma, increases the likelihood of an asthma diagnosis as an adult. Patients with asthma also often exhibit other inflammatory conditions, such as eczema.

The gold standard of an asthma diagnosis is pulmonary function testing. These tests provide precise information about how air flows into and out of the body. Moreover, **spirometry** testing (Table 11.3) measures:

- Forced vital capacity (FVC): the maximum volume of air that can be forcibly exhaled after fully inhaling
- Forced expiratory volume (FEV_1): the amount of that can be forcefully exhaled in one second

These measurements demonstrate specific patterns in asthma, assess the level of airflow obstruction, and provide information about disease severity. Spirometry tests are also used to assess airway changes in response to **bronchodilator** administration; bronchodilators open narrowed airways and allow a significant increase in the volume of air that can be inhaled and forcefully exhaled.

Spirometry Testing	What It Measures or Identifies
Forced vital capacity (FVC)	The maximum volume of air that can be forcibly exhaled after fully inhaling
Forced expiratory volume (FEV_1)	The amount of that can be forcefully exhaled in one second Expressed as a percent of predicted value Obstruction is defined as less than 0.8 (80 percent)
FEV_1/FVC ratio	Can identify if there is baseline airflow obstruction A reduced ratio indicates obstruction Obstruction is defined as less than 0.7

TABLE 11.3 Spirometry Testing

Exhaled nitric oxide measurement can be used to support an asthma diagnosis, though it is not considered conclusive. In some patients with asthma, airway inflammation leads to increased levels of nitric oxide during exhalation. Similarly, complete blood count test results can be used to support an asthma diagnosis. Elevated eosinophil levels can be present in allergic asthma (Fanta & Lange-Vaidya, 2022).

Nursing Care of the Patient with Asthma

While asthma is a treatable condition, there is the potential for serious complications and even death. Careful monitoring, robust patient education, and timely intervention are key interventions to optimize outcomes. Asthma diagnosis can range from intermittent, to persistent, allergy and exercise induced, pediatric and adult-onset, as well as overlap with other respiratory diseases like chronic obstructive pulmonary disease (COPD).

Recognizing Cues and Analyzing Cues

The nurse providing care to a patient with asthma utilizes both objective and patient-reported data to optimize care. Subjective data can include the presence of shortness of breath, wheezing, chest tightness, cough, increased mucus, activity limitations, and frequency of nighttime waking due to breathing difficulty. Vital signs are evaluated with a focus on respiratory rate and oxygen saturation. In periods of labored breathing, tachycardia may be present. The nurse performs auscultation, noting the location and character of any abnormal lung sounds. Expiratory wheezes are the most common adventitious lung sound in asthma. If the patient has a cough, the nurse asks about the frequency and characteristics; a nighttime cough is common with asthma.

Environmental irritants can trigger asthma exacerbations; ask the patient about exposure to allergens, secondhand smoke, and vapors. If the patient smokes or vapes, inquire about frequency and duration. Preventable respiratory illnesses can cause serious illness. Discuss immunization status and recommended vaccines as clinically appropriate. Patients may have to mask if they are susceptible to illness and in congested public areas.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Signs of respiratory distress and inadequate oxygenation are a high priority. The nurse may assist with spirometry testing and review results and administer medications such as bronchodilators and glucocorticoids. Patient education topics include using an inhaler and peak flow meter, strategies to avoid triggers, and implementing an asthma action plan (Figure 11.15, Figure 11.16, and Figure 11.17). An asthma action plan gives a patient detailed information about how to monitor symptoms and adjust medications when needed to prevent severe exacerbations.

ASTHMA ACTION PLAN

For: _____ Doctor: _____ Date: _____

Doctor's Phone Number: _____ Hospital/Emergency Department Phone Number: _____

GREEN ZONE

DOING WELL

- No cough, wheeze, chest tightness, or shortness of breath during the day or night
- Can do usual activities

And, if a peak flow meter is used,

Peak flow: more than _____
(80 percent or more of my best peak flow)

My best peak flow is: _____

Daily Medications

Medicine	How much to take	When to take it
_____	_____	_____
_____	_____	_____
_____	_____	_____

Before exercise ☐ _____ ☐ 2 or ☐ 4 puffs 5 minutes before exercise

YELLOW ZONE

ASTHMA IS GETTING WORSE

- Cough, wheeze, chest tightness, or shortness of breath, or
- Waking at night due to asthma, or
- Can do some, but not all, usual activities

–Or–

Peak flow : _____ to _____
(50 to 79 percent of my best peak flow)

1st **Add: quick-relief medicine—and keep taking your GREEN ZONE medicine.**

_____ (quick-relief medicine) _____ Number of puffs **or** ☐ Nebulizer, once Can repeat every _____ minutes up to maximum of _____ doses

2nd **If your symptoms (and peak flow, if used) return to GREEN ZONE after 1 hour of above treatment:**

☐ Continue monitoring to be sure you stay in the green zone.

–Or–

If your symptoms (and peak flow, if used) do not return to GREEN ZONE after 1 hour of above treatment:

☐ Take: _____ (quick-relief medicine) _____ Number of puffs **or** ☐ Nebulizer

☐ Add: _____ mg per day (oral steroid) For _____ (3–10) days

☐ Call the doctor ☐ before/ ☐ within _____ hours after taking the oral steroid.

FIGURE 11.15 An asthma action plan provides detailed information about how to monitor symptoms, adjust medications, and when to seek urgent help. The first part focuses on monitoring symptoms. (credit: "Asthma Action Plan" by United States-National Institute of Health: National Heart, Lung, Blood Institute, Public Domain)

RED ZONE

MEDICAL ALERT!

- Very short of breath, or
- Quick-relief medicines have not helped,
- Cannot do usual activities, or
- Symptoms are same or get worse after 24 hours in Yellow Zone

–Or–

Peak flow : less than _____
(50 percent of my best peak flow)

Take this medicine:

❑ _____
(quick-relief medicine)
_____ Number of puffs
or ❑ Nebulizer

❑ _____ mg
(oral steroid)

Then call your doctor NOW. Go to the hospital or call an ambulance if:

- You are still in the red zone after 15 minutes AND
- You have not reached your doctor.

DANGER SIGNS

- **Trouble walking and talking due to shortness of breath**
- **Lips or fingernails are blue**

→

- **Take _____ puffs of _____ (quick relief medicine)**
  AND
- **Go to the hospital or call for an ambulance _____ (phone) NOW!**

HOW TO CONTROL THINGS THAT MAKE YOUR ASTHMA WORSE

This guide suggests things you can do to avoid your asthma triggers. Put a check next to the triggers that you know make your asthma worse and ask your doctor to help you find out if you have other triggers as well. Keep in mind that controlling any allergen usually requires a combination of approaches, and reducing allergens is just one part of a comprehensive asthma management plan. Here are some tips to get started. These tips tend to work better when you use several of them together. Your health care provider can help you decide which ones may be right for you.

IRRITANTS

❑ Tobacco Smoke

- If you smoke, visit smokefree.gov or ask your health care provider for ways to help you quit.
- Ask family members to quit smoking.
- Do not allow smoking in your home or car.

❑ Smoke, Strong Odors, and Sprays

- If possible, avoid using a wood-burning stove, kerosene heater, or fireplace. Vent gas stoves to outside the house.
- Try to stay away from strong odors and sprays, such as perfume, talcum powder, hair spray, and paints.

❑ Vacuum Cleaning

- Try to get someone else to vacuum for you once or twice a week, if you can. Stay out of rooms while they are being vacuumed and for a short while afterward.
- If you must vacuum yourself, using HEPA filtration vacuum cleaners may be helpful.

FIGURE 11.16 This part of the asthma action plan monitors symptoms in the red zone and provides information on controlling it. (credit: "Asthma Action Plan" by United States-National Institute of Health: National Heart, Lung, Blood Institute, Public Domain)

HOW TO CONTROL THINGS THAT MAKE YOUR ASTHMA WORSE (CONTINUED)

ALLERGENS

❑ Dust Mites

These tiny bugs, too small to see, can be found in every home—in dust, mattresses, pillows, carpets, cloth furniture, sheets and blankets, clothes, stuffed toys, and other cloth-covered items. If you are sensitive:

- Mattress and pillow covers that prevent dust mites from going through them should be used along with high efficiency particulate air (HEPA) filtration vacuum cleaners.
- Consider reducing indoor humidity to below 60 percent. Dehumidifiers or central air conditioning systems can do this.

❑ Cockroaches and Rodents

Pests like these leave droppings that may trigger your asthma. If you are sensitive:

- Consider an integrated pest management plan.
- Keep food and garbage in closed containers to decrease the chances for attracting roaches and rodents.
- Use poison baits, powders, gels, or paste (for example, boric acid) or traps to catch and kill the pests.
- If you use a spray to kill roaches, stay out of the room until the odor goes away.

❑ Animal Dander

Some people are allergic to the flakes of skin or dried saliva from animals with fur or hair. If you are sensitive and have a pet:

- Consider keeping the pet outdoors.
- Try limiting to your pet to commonly used areas indoors.

❑ Indoor Mold

If mold is a trigger for you, you may want to:

- Explore professional mold removal or cleaning to support complete removal.
- Wear gloves to avoid touching mold with your bare hands if you must remove it yourself.
- Always ventilate the area if you use a cleaner with bleach or a strong smell.

❑ Pollen and Outdoor Mold

When pollen or mold spore counts are high you should try to:

- Keep your windows closed.
- If you can, stay indoors with windows closed from late morning to afternoon, when pollen and some mold spore counts are at their highest.
- If you do go outside, change your clothes as soon as you get inside, and put dirty clothes in a covered hamper or container to avoid spreading allergens inside your home.
- Ask your health care provider if you need to take or increase your anti-inflammatory medicine before the allergy season starts.

❑ Other Things That Can Make Asthma Worse

- Sulfites in foods and beverages: Do not drink beer or wine or eat dried fruit, processed potatoes, or shrimp if they cause asthma symptoms.
- Cold air: Cover your nose and mouth with a scarf on cold or windy days.
- Other medicines: Tell your doctor about all the medicines you take. Include cold medicines, aspirin, vitamins and other supplements, and nonselective beta-blockers (including those in eye drops).

FIGURE 11.17 This page of the asthma action plan provides additional ways to control asthma. (credit: "Asthma Action Plan" by United States-National Institute of Health: National Heart, Lung, Blood Institute, Public Domain)

Steroid inhalers can increase the risk of oral candida infections, so patient education should include rinsing the mouth after use, and use of spacers if indicated. In acute exacerbations, nursing interventions may include monitoring oxygen saturation and applying supplemental oxygen. The nurse collaborates with respiratory therapy and the provider to identify SpO2 targets and optimize oxygenation.

LINK TO LEARNING

The Asthma and Allergy Foundation of America has resources for patients and families. This video provides important teaching points (https://openstax.org/r/77AsthmaAllergy) about how to use inhalers, nebulizers, spacers, and chambers.

Evaluation of Nursing Care for the Patient with Asthma

Evaluating nursing care for patients with asthma centers around symptom assessment and management. Accurately understanding the patient's experience of symptoms improves the nurse's ability to evaluate outcomes.

The primary patient outcome related to asthma management is symptom frequency. The nurse evaluates how often the patient experiences symptoms, including how often the patient is awakened from sleep due to difficulty breathing. It is important to understand how often the patient experiences respiratory distress severe enough to warrant using rescue medications. Lung function can be evaluated using spirometry. In acute exacerbations, monitor oxygen saturation and requirements.

Medical Therapies and Related Care

Asthma treatment focuses on controlling current asthma symptoms and decreasing future complications. Collaborative care for patient and caregiver education is a key component of asthma care. The interprofessional team includes providers, nurses, respiratory therapists, and pharmacists. Patient education topics include medication administration, home monitoring, and strategies to prevent exacerbation. Patient education strategies may include videos, teaching materials, and hands-on demonstration. A personalized, written asthma action plan can help caregivers and patients stay safe. These can include contact information for clinical team members, a medication list with instructions, clear information on how to manage flares, and when to seek help or call 911. A home **peak flow meter** (Figure 11.18) allows patients to track and observe trends in their lung function.

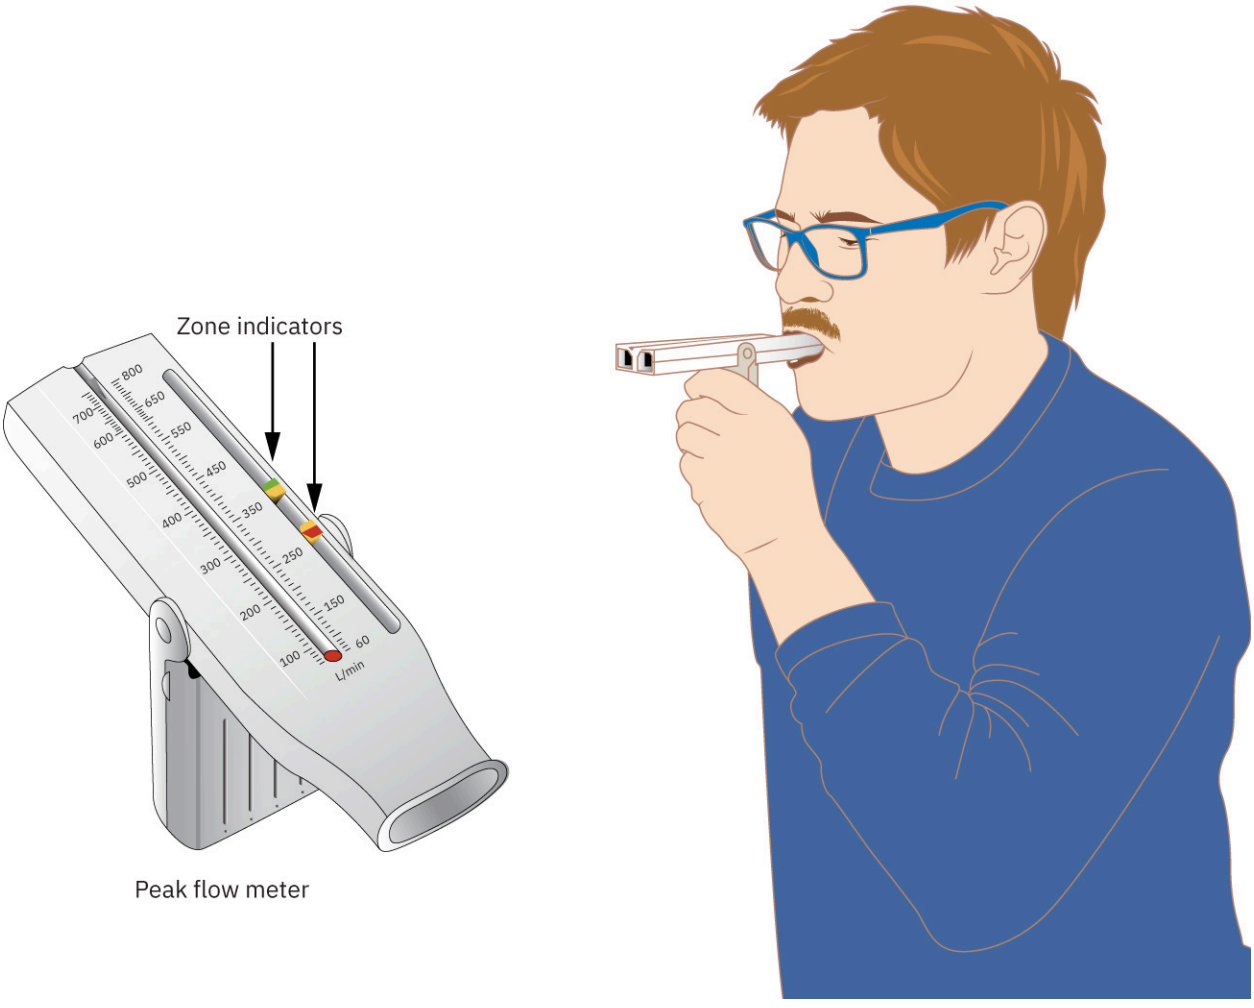

FIGURE 11.18 A peak flow meter is used to allow patients to track and observe trends in their lung function. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Identifying triggers and controlling exposure is important for patients with asthma. Some triggers (e.g., exercise, significant emotions, hormonal fluctuations, respiratory illnesses) cannot be avoided. In those cases, awareness of

their personal response to various triggers can help patients to anticipate and manage symptoms.

During times when an asthma patient is experiencing acute shortness of breath, short-acting beta-agonists (SABAs) are bronchodilators used to decrease bronchoconstriction. These are considered "rescue" medications because they start working within fifteen to thirty minutes. Medications in this class include albuterol and levalbuterol. In severe flares, oral or intravenous corticosteroids are often necessary to decrease inflammation. Medications used to treat asthma are summarized in Table 11.4.

Medication Class	Example	Additional Information
Short-acting beta-agonist (SABA)	Albuterol Levalbuterol	Inhaled or nebulized Onset of action: 15 to 30 minutes Considered "rescue" medications
Long-acting beta-agonist (LABA)	Salmeterol Formoterol	Oral, inhaled, or nebulized
Inhaled corticosteroids	Budesonide Fluticasone propionate	In severe flares, oral or IV corticosteroids are used.
Leukotriene inhibitors	Montelukast	Oral Can prevent asthma symptoms and treat allergy symptoms
Long-acting muscarinic antagonist (LAMA)	Tiotropium	Used in moderate cases Dry powder or mist inhaler
Mast cell stabilizers	Cromolyn	Can be used to treat allergic responses and prevent exercise-induced symptoms Rarely used due to more effective treatment options
Methylxanthine	Theophylline	Used to treat bronchoconstriction Rarely used due to more effective treatment options

TABLE 11.4 Asthma Medications

Long-term medication management focuses on reducing chronic inflammation. These medications can include long-acting beta-agonists (LABAs), like salmeterol or formoterol, inhaled corticosteroids, and leukotriene inhibitors, like montelukast. Some inhalers combine corticosteroid with a LABA. Inhaled long-acting muscarinic antagonists (LAMAs), like tiotropium, are used in moderate cases. Additionally, mast cell stabilizers, such as cromolyn, can be used to treat allergic responses and prevent exercise-induced symptoms. Theophylline is a methylxanthine that is sometimes used to treat bronchoconstriction.

11.5 Disorders of the Lower Respiratory System: Chronic Obstructive Pulmonary Disease

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for chronic obstructive pulmonary disease
- Describe the diagnostics and laboratory values in the disease of chronic obstructive pulmonary disease
- Apply nursing concepts and plan associated nursing care for the patient with chronic obstructive pulmonary disease
- Evaluate the efficacy of nursing care for the patient with chronic obstructive pulmonary disease
- Describe the medical therapies that apply to the care of chronic obstructive pulmonary disease

One widely prevalent obstructive respiratory disease is **chronic obstructive pulmonary disease (COPD)**. Thirteen percent of American adults (age forty to seventy-nine) have COPD. Most cases are linked to cigarette smoking, though COPD can occur in people who have never smoked. Some studies suggest that exposure to secondhand smoke increases the risk of COPD. It can cause chronic illness, hospitalization, and death. Annually, the United States sees 120,000–140,000 deaths attributable to COPD. COPD is more common in Black Americans than in other groups. There is a slightly higher prevalence of cases in males compared with females (Avital & Oji, 2021).

Pathophysiology

COPD is a chronic condition characterized by inflammation of the airways, blood vessels, and lung tissues that obstruct gas exchange. Most commonly, an irritant (e.g., smoking) causes dangerous levels of inflammation. This results in changes to the airways, including narrowing, smooth muscle hypertrophy, and increased mucous production. Over time, scar tissue can form and cause further narrowing of the airways. When alveolar walls become damaged and lose elasticity, resulting in problems with exhalation and CO_2 trapping, **emphysema** occurs (Figure 11.19).

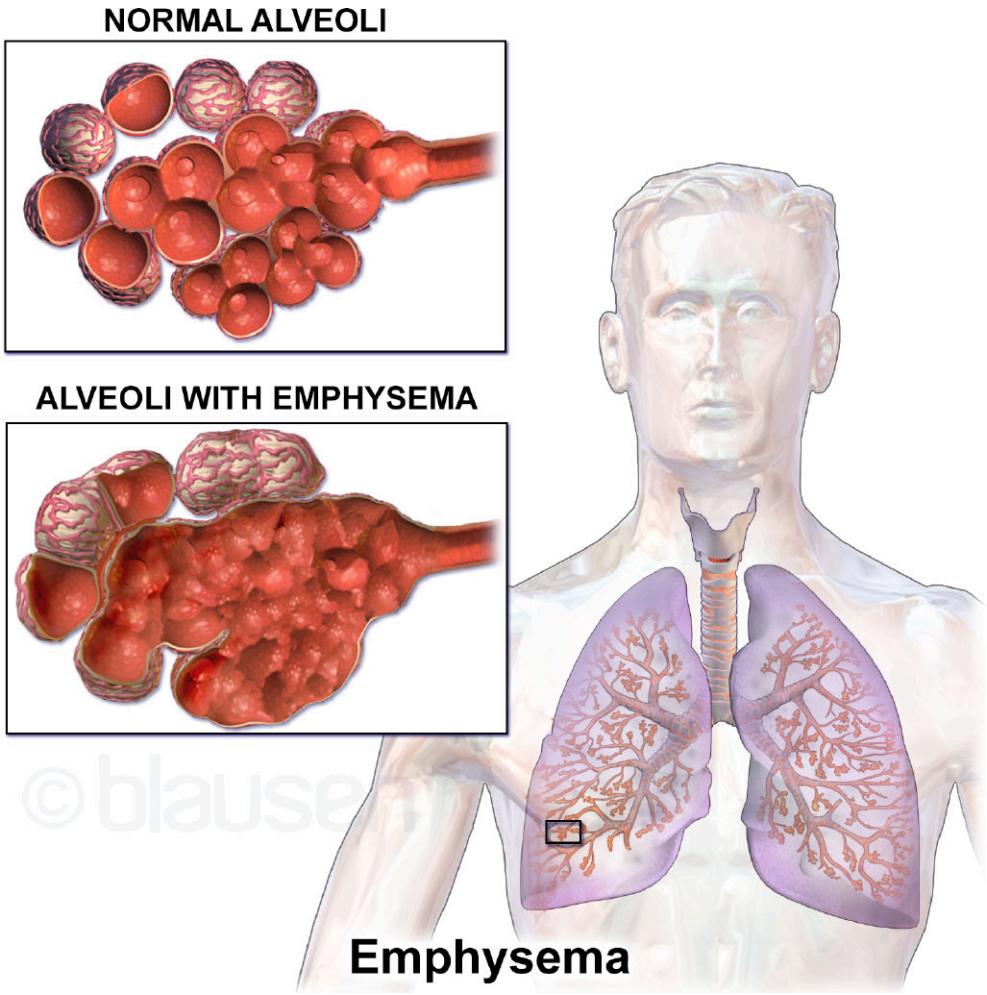

FIGURE 11.19 In COPD, emphysema occurs where alveolar walls become damaged and lose elasticity, resulting in problems with exhalation and CO2 trapping. (credit: "Blausen 0343 Emphysema" by Blausen Medical Communications, Inc./Wikimedia Commons, CC BY 3.0)

In rare cases, alpha-1 antitrypsin deficiency causes COPD. This genetic disorder results in misfolded, mutated proteins that build up in the liver. A lack of alpha-1 antitrypsin means that the body is unable to neutralize an enzyme that, when unchecked, can overwork and increase the risk of lung damage. Unlike smoking-related COPD, COPD caused by alpha-1 antitrypsin deficiency typically only affects the lower lobes of the lungs (Agarwal et al., 2023).

Risk Factors

Cigarette smoking is the most significant risk factor for COPD. Typically, a smoking history of more than ten to fifteen pack-years is seen with COPD. Occupational or environmental exposures to dust and fumes account for the approximately 20 percent of COPD patients who are nonsmokers (Han et al., 2023). Secondhand smoke and alpha-1 antitrypsin deficiency are additional risk factors for developing COPD (Agarwal et al., 2023).

Clinical Manifestations

COPD generally presents in adults, with the initial onset of problematic symptoms occurring more often during winter months due to irritation from cold air. Patients will report a cough, progressive shortness of breath, and mucous production.

Physical assessment may reveal wheezing. Patients with COPD may demonstrate a prolonged expiratory phase. Because exhalation becomes difficult in COPD, air becomes trapped in the lungs. The anterior-posterior chest wall diameter can increase and become barrel shaped from the chronic air trapping. Because of the increased effort required to breathe, patients with chronic COPD can develop muscle wasting and **cachexia**, a disorder that causes loss of muscle and adipose tissue (Figure 11.20). Clubbing of the fingers can occur due to chronic hypoxia. In severe

cases and during acute exacerbations, patients may experience noticeable respiratory distress. Manifestations can include accessory muscle usage, pursed lip breathing, and cyanosis. In advanced cases, right-sided heart failure can occur, causing lower extremity edema (Agarwal et al., 2023).

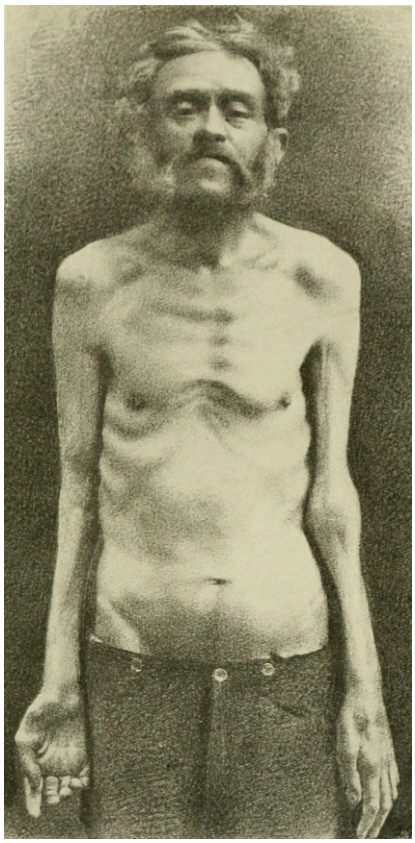

FIGURE 11.20 Muscle wasting and cachexia are often the result of COPD. (credit: “Image from page 812 of "Internal medicine; a work for the practicing physician on diagnosis and treatment, with a complete Desk index" (1920)” by Internet Archive Book Images/Flickr, Public Domain)

REAL RN STORIES

Nurse: Hannah, student nurse
Years in Practice: Less than one
Clinical Setting: Medical-surgical unit
Geographic Location: Atlanta, Georgia

At Hannah’s first clinical site, she was assigned to a patient with advanced COPD. Hannah had completed prework before clinical and understood that the patient would likely be using oxygen therapy and may have some activity limitations due to dyspnea.

As she entered the room to introduce herself to the patient, she was shocked by the patient’s appearance. In hindsight, she should have anticipated that the patient might have cachexia, but that day it took her by surprise: the patient was skin and bones. Because of the patient’s extremely thin extremities, Hannah needed to use a very small blood pressure cuff when doing vital signs. As she observed the RN administer a subcutaneous medication, it was clear that the patient had almost no subcutaneous tissue. The nurse struggled to find a location with enough fat to administer the subcutaneous medication.

Hannah and her classmate helped the patient get washed up. Because the patient was so dyspneic with any exertion, the two student nurses needed to complete the entire bed bath for the patient. As they helped the patient lift their limbs and wash, both students noticed that even the patient’s underarms showed signs of cachexia as the pocket of the underarm was so deep.

In postconference, the nursing instructor asked about the patient's diet order. Hannah recalled the patient was ordered a low-fat/low-cholesterol diet due to hyperlipidemia. The instructor reminded the group that for patients with advanced COPD and severe dyspnea, this diet was perhaps not the best choice. Sometimes a high-calorie, high-fat diet is a better option for a malnourished patient where every bite counts. The students learned that often COPD patients must choose between food and breathing as they can't do both at the same time when breathing is labored and limited.

Assessment and Diagnostics

COPD is assessed during initial diagnosis, ongoing treatment, and during acute exacerbations. Precise testing can provide important information about lung function. Other than diagnostic findings, the nurse might notice clues, such as tripod positioning, pursed lip breathing, and lower oxygenation saturation with exacerbation.

COPD is diagnosed and staged with pulmonary function tests using spirometry. Lung function may be evaluated before and after administration of an inhaled bronchodilator. The maximum exhaled volume in one second (**forced expiratory volume** [FEV_1]) is compared with the overall maximum volume that can be exhaled (**forced vital capacity** [FVC]). If the ratio of forced expiratory volume in one second to forced vital capacity (FEV_1/FVC) is under 0.7, or 70 percent of predicted, COPD is present. After a diagnosis of COPD is confirmed, severity is identified using the Global Initiative for Chronic Obstructive Lung Disease (GOLD) classification system, which is the gold standard for diagnosis. This compares the patient's actual FEV_1 to the expected FEV_1. A higher FEV_1 indicates that the disease is mild, and the patient is closer to normal lung function. A lower FEV_1 indicates diminished lung function and increased disease severity.

- GOLD 1: mild disease; the FEV_1 is >/= 80 percent of the predicted value.
- GOLD 2: moderate disease; the FEV_1 is 50–79 percent of the predicted value.
- GOLD 3: severe disease; the FEV_1 is 30–49 percent of the predicted value.
- GOLD 4: very severe disease; the FEV_1 is < 30 percent of the predicted value.

Laboratory testing may be performed. A complete blood test is used to evaluate anemia, infection, and polycythemia. If alpha-1 antitrypsin deficiency is suspected, these levels can be evaluated with a blood test. Diagnostic imaging, such as chest x-rays and computed tomography (CT scans), may be used to evaluate disease progression and acute infections.

An acute exacerbation usually presents with increased dyspnea, increased sputum volume, and purulent sputum. In a mild exacerbation, at least one of those assessment findings will be present, plus one of the following additional symptoms:

- increased wheezing
- increased cough
- fever without another cause
- recent upper respiratory infection (within five days)
- increased heart rate compared with baseline
- increased respiratory rate compared with baseline

Moderate and severe exacerbations will have two or three of the following: worsening shortness of breath, increased volume of sputum, and/or purulence.

When a low oxygen level is present or suspected, pulse oximetry and arterial blood gas analysis can provide helpful information that can guide therapy, including oxygen administration. Arterial blood gas analysis can also be used to assess elevated levels of carbon dioxide (> 45 mmHg) (Agarwal et al., 2023). Patients with mild or moderate COPD will often have arterial blood gas results that demonstrate mildly low oxygen levels without elevated CO_2 levels. Over time, as COPD becomes more severe, oxygen levels drop, and elevated CO_2 can occur. Respiratory acidosis is the most common blood gas abnormality in COPD. Adequate CO_2 clearance is not possible due to lung damage. CO_2 levels rise, decreasing the pH to an acidotic level (Han et al., 2023).

Nursing Care of the Patient with COPD

Nursing care of the patient with COPD takes place during initial diagnosis or ongoing treatment. When interviewing a

patient, careful listening can provide important clues about respiratory and functional status.

INTERDISCIPLINARY PLAN OF CARE

Interdisciplinary Plan of Care for a Patient with COPD

The interdisciplinary plan of care includes a variety of health-care professionals who work together to coordinate care for a patient with COPD. Their goal is to provide continued care, management, and preventative measures to reduce readmission to the hospital for acute episodes of exacerbation. The interdisciplinary team includes the following:

- Diagnostic imaging team to perform CXRs, and blood sampling collection
- Pharmacists to manage medications and verify compatibility
- Nutritionists to provide disease specific meal plans and supplements
- Social workers to collaborate post-discharge resources and referrals
- Therapists, including occupational, physical, recreational, and speech language
- Providers: pulmonologist/primary care to oversee the patient's plan of care
- COPD educators to provide best practices to prevent acute episodes and improve quality of life at home
- Cardiopulmonary team to perform cardiopulmonary rehab in an outpatient setting
- Home care providers to arrange services in the home post discharge

Recognizing Cues and Analyzing Cues

The nurse caring for a patient with COPD integrates objective data with the patient's subjective observations. The patient may report subjective symptoms, including a cough, worsening shortness of breath, and mucous production. Additionally, many patients will have a history of smoking or exposure to environmental irritants. Inquire about the frequency and duration of exposure to cigarette smoke and other irritants. Because preventable respiratory illnesses can cause serious infections in patients with COPD, ask patients about their immunization status.

Objectively, vital signs are evaluated with a focus on respiratory rate and oxygen saturation. Lung auscultation may reveal wheezing. Patients with COPD may demonstrate a prolonged expiratory phase. Physical assessment can also reveal a barrel-shaped chest, with increased anterior-posterior diameter. In patients with long-standing disease, muscle wasting, cachexia, and digital clubbing may be present. Physiological causation of clubbing is not entirely understood (Burcovschii & Aboeed, 2022). When evaluating for a COPD exacerbation, the nurse observes one or more of the key assessment findings to diagnose COPD.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

In patients with COPD, signs of inadequate oxygenation and respiratory distress are a high priority. The nurse may assist with spirometry testing and review results with the patient, and administer medications, such as bronchodilators and glucocorticoids. Educational topics include smoking cessation, infection prevention, vaccination, and how to use inhaled medications. Because steroid inhalers can increase the risk of oral *candida* infections, rinsing the mouth after use is an important teaching point. Educate also on the correct usage of spacers to decrease infection. Dyspnea can limit a patient's activity tolerance, meaning energy conservation strategies (e.g., activity pacing) can be helpful. In patients who struggle with activities of daily living due to dyspnea, nutritional coaching and interventions can be helpful. High-calorie foods can be a good choice when dyspnea makes eating challenging. When chronic oxygen therapy is utilized, patient teaching also addresses oxygen safety.

In acute exacerbations, nursing interventions may include monitoring oxygen saturation and applying supplemental oxygen. The nurse collaborates with respiratory therapy and the provider to identify SpO_2 targets and optimize oxygenation. Because of the risk of CO_2 retention, the nurse should assess for signs of elevated CO_2 levels thirty to sixty minutes after oxygen therapy is initiated (Han et al., 2023). Pulmonary rehabilitation may be indicated. In pulmonary rehabilitation, a supervised coaching program helps people with chronic lung disease optimize their respiratory status through various breathing techniques and exercises. Pulmonary rehabilitation assists patients to increase exercise with less symptom burden (Terry & Dhand, 2023).

Evaluation of Nursing Care for the Patient with COPD

Nursing care for patients with COPD involves assessing both respiratory and functional status. As disease progresses, and during acute exacerbations, pulmonary status can worsen and difficulties with ADLs can occur. The most important outcomes related to COPD focus on symptom management, oxygen level, activity tolerance, and prevention of exacerbations. The nurse evaluates symptom severity and how it affects the patient's ability to perform activities of daily living. Spirometry testing is used to identify changes in lung function. In acute exacerbations, signs of infection, oxygen saturation, and oxygen requirement are monitored.

Medical Therapies and Related Care

COPD treatment focuses on controlling current symptoms and decreasing the risk of exacerbations. The interprofessional team includes nurses as well as respiratory therapists, providers, physical therapists, occupational therapists, dietitians, and pharmacists. Pulmonary rehabilitation therapy can help patients improve endurance and activity tolerance.

Many of the strategies used to treat COPD are like those used to treat asthma. Smoking cessation is a cornerstone of treatment. Infection prevention, including influenza and pneumococcal vaccines, can provide important prevention against serious illness. Several types of bronchodilators are used in treatment and maintenance. Beta-2 agonists work by dilating the smooth muscles in the airway; they can be short-acting or long-acting. Short-acting beta-2 agonists are used for acute treatment, while long-acting beta-2 agonists are used for long-term therapy. Antimuscarinics keep airways open by preventing bronchoconstriction. Like beta-2 agonists, antimuscarinic agents can be short-acting or long-acting. Methylxanthines are a long-acting therapy; they cause bronchodilation by relaxing smooth muscle. Some studies support the use of prophylactic azithromycin to decrease the number of exacerbations in COPD patients (Agarwal et al., 2023).

Inhaled corticosteroids are commonly used to decrease airway swelling and are used as long-term therapy. Phosphodiesterase-4 inhibitors, such as Roflumilast, reduce inflammation and are used in patients with severe disease. In some patients, long-term use of azithromycin can decrease the likelihood of exacerbations. Despite medication and pulmonary rehabilitation, most patients with COPD will eventually have low oxygen levels, even at rest. Chronic oxygen therapy is a common treatment that can improve symptoms and lengthen survival. Surgery is sometimes used to treat severe cases. Surgical options include removal of damaged lung areas, surgery to decrease overall lung volume, and lung transplantation.

Acute exacerbations of COPD can require additional therapy. Oral and parenteral glucocorticoids are utilized for short-term treatment of acute exacerbations. Antibiotics may be necessary if there is a confirmed or suspected bacterial infection. The GOLD strategy supports starting antibiotics empirically when sputum is increasing in purulence or volume, dyspnea is increasing, or ventilatory support is needed (Terry & Dhand, 2023). Supplemental oxygen, up to and including ventilator support, may be necessary (Agarwal et al., 2023). Pulmonary rehabilitation can be a valuable intervention to improve quality of life.

11.6 Disorders of the Lower Respiratory System: Pneumothorax

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations of pneumothorax
- Describe the diagnostics and laboratory values in the disease of pneumothorax
- Apply nursing concepts and plan associated nursing care for the patient with pneumothorax
- Evaluate the efficacy of nursing care for the patient with pneumothorax
- Describe the medical therapies that apply to the care of pneumothorax

The pleural space typically contains only 10 to 20 milliliters of pleural fluid. When air enters pleural space, a pneumothorax develops. Each year, approximately 20,000 cases of pneumothorax occur in the United States. The large umbrella diagnosis of pneumothorax includes both traumatic and nontraumatic cases (Table 11.5). Nontraumatic pneumothoraxes are further categorized into primary spontaneous pneumothorax, secondary spontaneous pneumothorax, and iatrogenic. All types of pneumothoraxes are more common in males. Primary spontaneous pneumothorax is most common in individuals ages twenty to thirty. Secondary spontaneous

pneumothorax is most prevalent in older adults, ages sixty to sixty-five.

Type of Pneumothorax	Cause
traumatic pneumothorax	Air enters the pleural space due to a traumatic injury
Nontraumatic pneumothoraxes	
primary spontaneous pneumothorax	Air enters the pleural space spontaneously; there is *no underlying lung disease*.
secondary spontaneous pneumothorax	Air enters the pleural space spontaneously *as a complication of underlying lung disease*.
iatrogenic pneumothorax	Air enters the pleural space due to a complication from a surgery or invasive procedure (e.g., placement of a central venous catheter).

TABLE 11.5 **Types of Pneumothorax**

Pathophysiology

The pleural space is the area between the inner (visceral) pleural layer and the outer (parietal) pleural layer. Under normal circumstances, the two pleural layers are separated by only a small volume of pleural fluid (Figure 11.21). Pneumothorax occurs when air enters the pleural space. Air can enter the pleural space when there is trauma through the chest wall, or if there is a rupture of the inner (visceral) pleural layer. The accumulation of air increases pressure, causing the lung to collapse and deflate. As a result of collapse and deflation, the lung area available for oxygenation and ventilation is dramatically decreased.

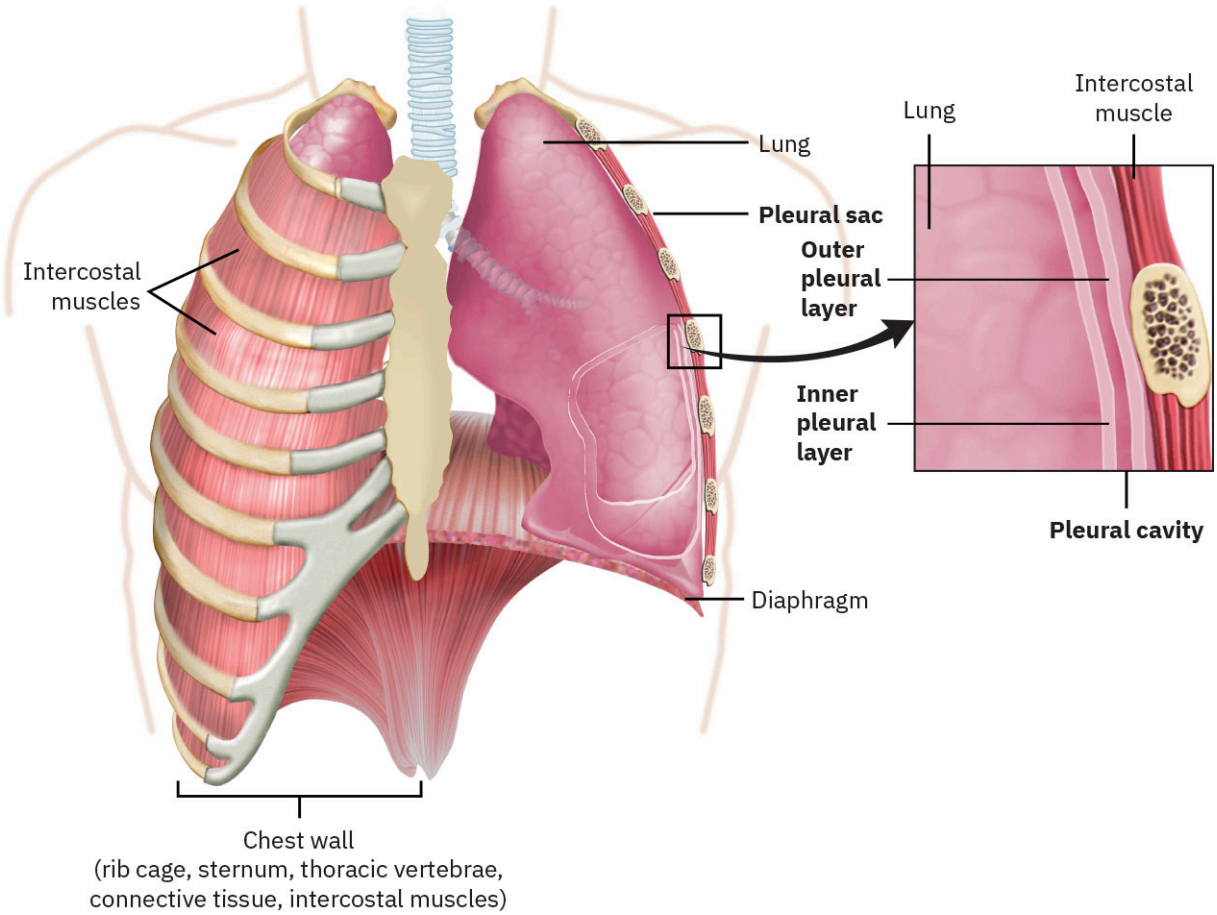

FIGURE 11.21 The lung is surrounded by the outer (parietal) and inner (visceral) pleura. The space between is called the pleural space. Under normal circumstances, the pleural space contains only 10 to 20 mls of pleural fluid. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The volume of air that has entered the pleural space affects the degree of lung collapse. When a small volume of air enters the pleural space, the degree of collapse may be minor. With a large volume of air, a **tension pneumothorax** can occur. In addition to causing a major amount of lung collapse, the large volume of air exerts high pressure; this can force the heart and trachea to shift (Figure 11.22).

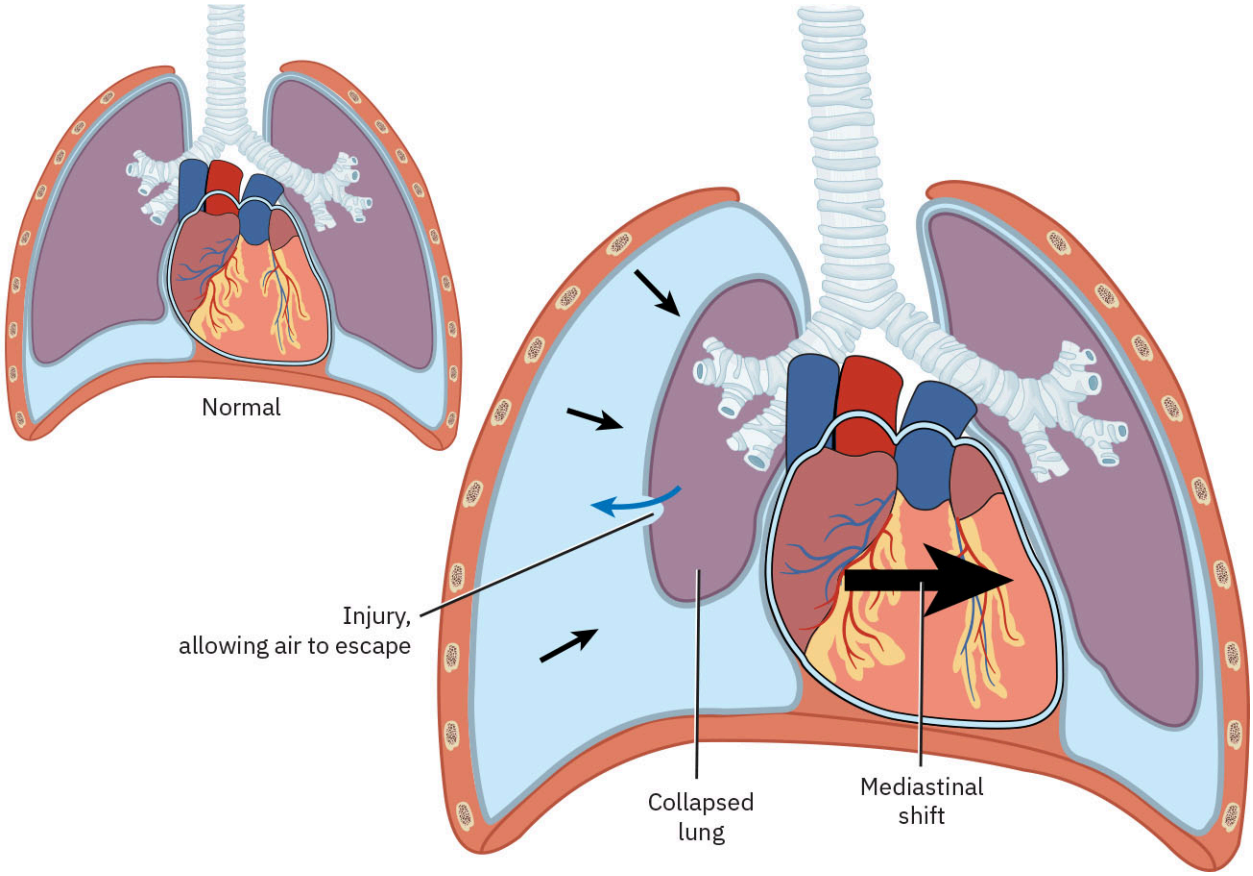

FIGURE 11.22 A tension pneumothorax occurs when air enters the pleural space and causes the lung to collapse. If the volume of air is large, it will force the heart and lungs to shift. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Risk Factors

Pneumothorax can occur as a result of many medical conditions, especially respiratory diseases such as COPD, asthma, cystic fibrosis, pneumonia, and tuberculosis. Smoking, pregnancy, and a family history of pneumothorax also increase a patient's risk. Various medical procedures, such as lung biopsy, tracheostomy placement, or placement of a central venous catheter, carry a risk of pneumothorax (McKnight & Burns, 2023). Patients with COPD have a significantly higher incidence of pneumothorax when compared with non-COPD patients. For heavy smokers, the risk of pneumothorax is 102 times higher when compared with nonsmokers (McKnight & Burns, 2023).

Clinical Manifestations

The high pressure of the air in the pleural space collapses the lung, limiting the body's ability to oxygenate and ventilate. While a patient with a small pneumothorax may be asymptomatic, most patients will have symptoms. Respiratory distress is a common clinical manifestation of pneumothorax. Patients commonly report a rapid onset of dyspnea, cough, and intense chest pain that is worse with movement.

Vital sign abnormalities can include an increased respiratory rate, decreased oxygen saturation, and increased heart rate. Physical assessment findings can include unequal chest expansion and decreased or absent breath sounds. When high pressure air is forced through the tissues, **subcutaneous emphysema** can occur. This creates a "popping" sensation with palpitation and can cause visible swelling. If the pneumothorax is a result of penetrating trauma through the chest wall, a wound may be visible. With tension pneumothorax, low blood pressure, cyanosis, and **tracheal deviation** (trachea in a non-midline position) can occur (McKnight & Burns, 2023).

Assessment and Diagnostics

Prompt diagnosis of pneumothorax is essential to prevent the possibility of life-threatening complications. Imaging and physical assessment are utilized to identify signs of pneumothorax. It is imperative the nurse realize that without immediate intervention, the patient's life is at risk.

Pneumothorax is diagnosed using imaging to visualize the area of collapsed lung. Most often, x-ray is used, although CT scan and ultrasound can also be utilized. Pulse oximetry and blood gas analysis may be performed, but results indicating low oxygen level can occur with many medical conditions and are not specific to pneumothorax. However, tension pneumothorax is an emergency, and treatment needs to be initiated immediately, without waiting for imaging (McKnight & Burns, 2023).

READ THE ELECTRONIC HEALTH RECORD

Assessment of a Patient with a Pneumothorax

Patient Information
Name: Charles Brenman
Age: 47 years
Sex: Male
Chief complaint:

- Severe shortness of breath and sharp stabbing chest pain

Medical history:

- Diagnosed with hypertension 3 years ago.
- Previous episodes last year of mild spasms related to gallstones, treated successfully with antispasmodics and diet change; no recurrence noted

Vital signs:

- Temperature: 93.3°F
- Heart rate: 132 bpm
- Blood pressure: 152/94 mm Hg
- Respiratory rate: 32 breaths per minute
- Oxygen saturation: 82% on room air
- BMI: 34

Recent laboratory results:

- WBC count: 10,000 /µL (normal)
- Hemoglobin: 13.5 g/dL (normal)
- Hematocrit: 40.5% (normal)
- Platelets: 250,000 /µL (normal)
- Electrolytes:
  - Sodium: 138 mmol/L (normal)
  - Potassium: 4.0 mmol/L (normal)
  - Chloride: 102 mmol/L (normal)

Imaging results:

- Ultrasound of chest: Findings consistent with small pneumothorax. The presence of a visible rim of less than 2 cm between the lung margin and the chest wall

Progress notes:

- Patient reports sudden onset of sharp pleuritic chest pain and shortness of breath, after falling off a ladder.
- Mild diaphoresis observed upon admission.
- Otherwise presents as an active middle-aged adult with mild health disparities

Current medications:

- Acetaminophen 500 mg every night as needed for pain
- Norvasc 10 mg a day day for hypertension

2. What information is the most concerning?

3. What is an expected finding?
4. What information should you question?

Nursing Care of the Patient with Pneumothorax

Nursing care for a patient with pneumothorax focuses on prompt identification of potential respiratory and circulatory compromise. Anticipating and preparing for potential treatment interventions are key nursing roles.

Recognizing Cues and Analyzing Cues

The nurse caring for a patient with suspected or confirmed pneumothorax synthesizes patient-reported subjective data and objective assessment findings. Self-reported symptoms may include a rapid onset of dyspnea, cough, and intense chest pain that worsens with movement. The nurse may inquire about the patient's past medical history, especially any known lung diseases.

Objectively, vital signs are evaluated with a focus on respiratory rate and oxygen saturation. Respiratory rate may be increased while oxygen saturation may be decreased. Lung auscultation may reveal diminished or absent breath sounds in the affected lung field(s), and unequal chest expansion may be present. Skin assessment may demonstrate subcutaneous emphysema, which can cause the skin to appear swollen and has a popping sensation with palpation. If the pneumothorax occurred as a result of a traumatic injury, a penetrating wound may be visible (McKnight & Burns, 2023).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

In patients with pneumothorax, signs of respiratory distress and decreased oxygenation are a high priority. The nurse may need to monitor vital signs, administer oxygen, or prepare a patient for imaging and/or procedures. If there is an open chest wound from a penetrating trauma, or if a chest tube becomes dislodged, the nurse must be ready to apply a three-sided occlusive dressing, which allows trapped air to escape while preventing more air from entering. If signs of tension pneumothorax are present, the nurse should anticipate emergent treatment due to the risk of decompensation and death. Tension pneumothorax is treated with immediate needle decompression, also known as needle thoracostomy. A needle is inserted between ribs into the pleural space, which allows the air that has accumulated in the pleural space to escape out of the body.

If a chest tube is inserted, it's important for the nurse to ensure that the tube from the patient is securely connected to the drainage device. Additionally, the nurse monitors output, evaluates the dressing at the insertion site, and, if ordered by the provider, may connect suction to the drainage device (McKnight & Burns, 2023).

Evaluation of Nursing Care for the Patient with Pneumothorax

When evaluating nursing care for patients with pneumothorax, respiratory assessment provides important information about patient status. Over time, respiratory status should improve as the air in the pleural space decreases. The most important outcomes related to pneumothorax center on improved oxygenation and lung reexpansion. The nurse monitors pulse oximetry, oxygen requirement, and lung sounds. Repeat imaging may be ordered and evaluated. If a chest tube is present, the nurse assesses the chest drainage system. As the pneumothorax resolves, the nurse should observe decreased air output (McKnight & Burns, 2023).

Medical Therapies and Related Care

Medical therapies vary based on the severity of the pneumothorax. Collaboration between nurses, physicians, and respiratory therapists is needed for optimal outcomes. Patients with a small, asymptomatic pneumothorax may not require any treatment because the body will reabsorb air in the pleural space over time. Some minor cases of pneumothorax are treated with high flow oxygen administration. Oxygen speeds up the body's ability to reabsorb air from the pleural space.

If the patient is symptomatic, the size of the pneumothorax is larger, or with a pneumothorax that occurs secondary to a disease (e.g., COPD, pneumonia), a provider may aspirate the pneumothorax using a needle (Figure 11.23). The needle is inserted between ribs, into the pleural space, and allows accumulated air to flow out of the body. For some patients, aspiration will be adequate treatment. If the patient's clinical status does not improve, the next treatment option is a thoracostomy tube placed by a provider. A **thoracostomy tube**, also referred to as a **chest tube**, is a tube

inserted through the skin into the pleural space, to drain air, fluid, or blood (Figure 11.24). Both procedures have the potential for moderate to severe pain. The nurse may advocate for, administer, and monitor the effects of analgesia.

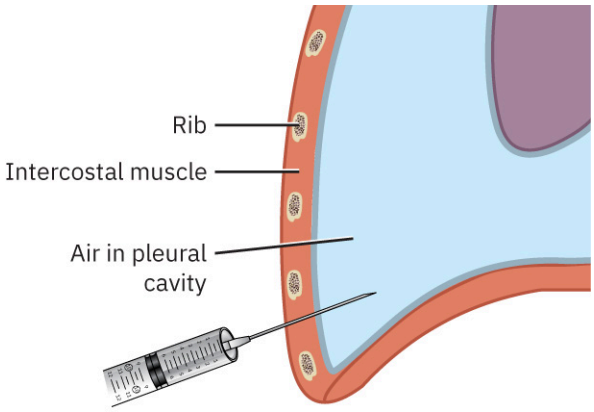

FIGURE 11.23 The provider inserts a thoracostomy tube through the skin into the pleural space, to drain air, fluid, or blood. This skilled procedure takes extensive training and is usually performed by a specialist such as a pulmonologist or emergency medicine provider. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

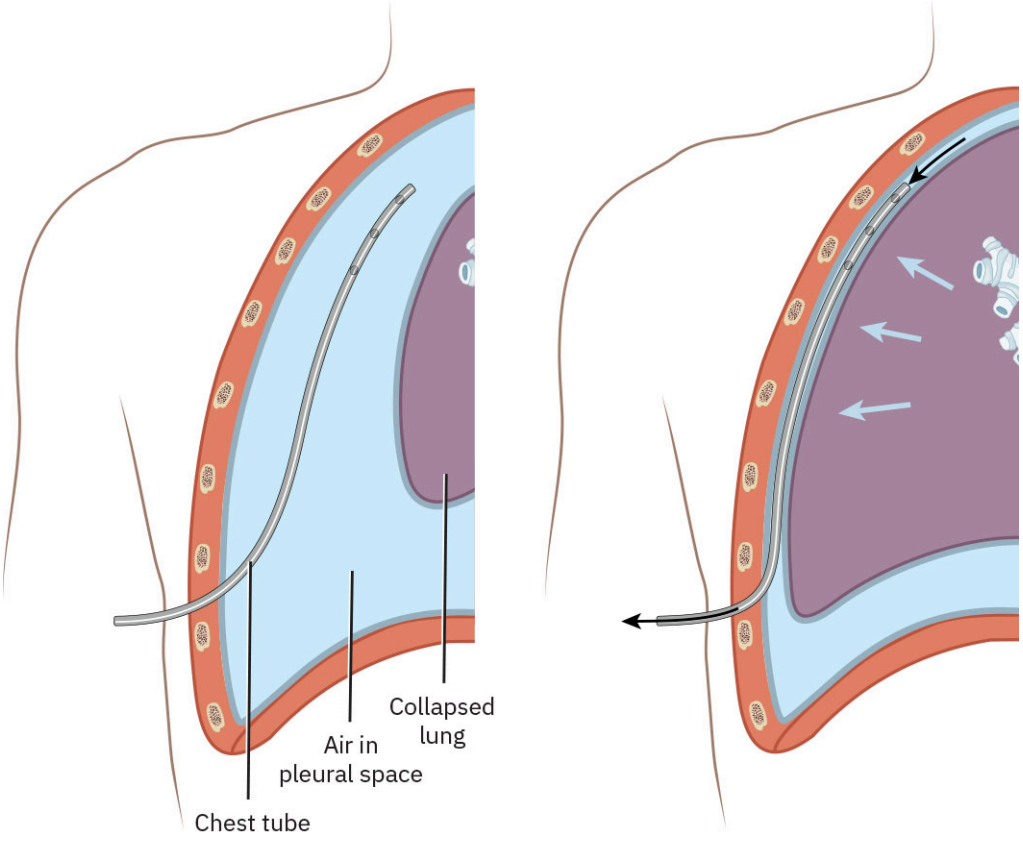

FIGURE 11.24 A thoracostomy tube, also referred to as a chest tube, is inserted through the skin into the pleural space. It can drain air, fluid, or blood. As these accumulated substances leave the pleural space, the lung can reexpand, improving oxygenation. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

To prevent air in the room from traveling through the chest tube and into the patient's pleural space, the chest tube needs to be connected to a specialized drainage device (Figure 11.25). While there are a variety of device models and manufacturers, all of these devices are designed for one-way drainage. This means that air and fluids can flow out of the body, but nothing can flow back in. To help the air drain out of the patient, suction needs to be applied to the chest drainage device. The amount of wall suction is specified in the provider order.

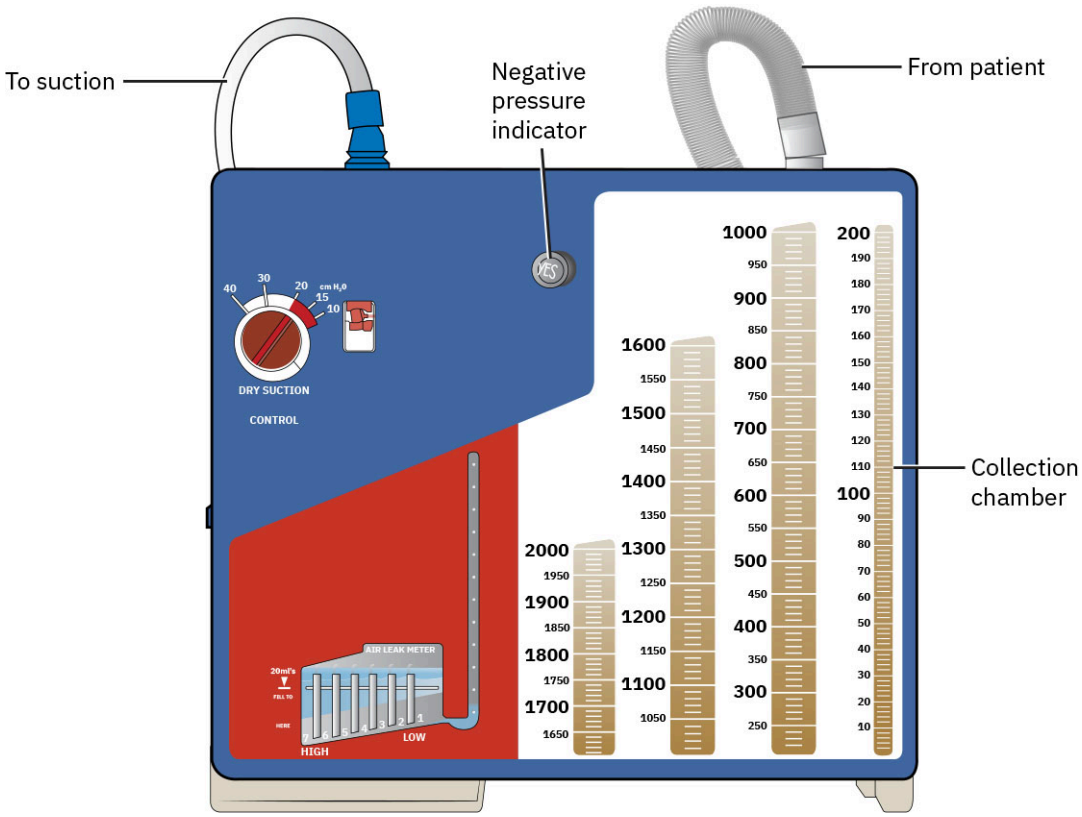

FIGURE 11.25 A specialized drainage device is connected to a thoracostomy tube (chest tube). All drainage devices are designed for one-way drainage, though different manufacturers and models exist. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Parts of the drainage device are:

- Collection chamber: This is where any fluid evacuated from the pleural space collects. Milliliter markings allow the amount of drainage to be quantified.
- Water seal/air leak monitor: In most devices, the water seal maintains one-way drainage, though some achieve this without a water seal area. This area can also show evidence of air moving through the system. When a pneumothorax is being treated, the device pulls air from the pleural space through the drainage system, so bubbles are expected to appear here as air flows through the system. When a chest tube drainage device is used to evacuate fluids from the pleural space, bubbles are not expected to appear here, and can indicate a break in the system.
- Suction control: The suction control dial indicates how much suction will be delivered to the patient when adequate wall suction is applied.
- Bellows: The bellows is used to determine if adequate wall suction has been applied. Typically, there is a marking where the bellows should expand.

If penetrating chest trauma is the cause of the pneumothorax, a temporary dressing may be necessary while more definitive treatment is in progress (Figure 11.26). To complete this process:

- An occlusive material (for example, Vaseline gauze, or something plastic) is placed over the wound.
- The dressing is taped in place fully on three edges, leaving an opening on one side.
- When the patient breathes in, the dressing is pulled toward the skin, sealing the opening, and preventing air from entering.
- When the patient exhales, air from the pleural space can escape through the open part of the dressing.

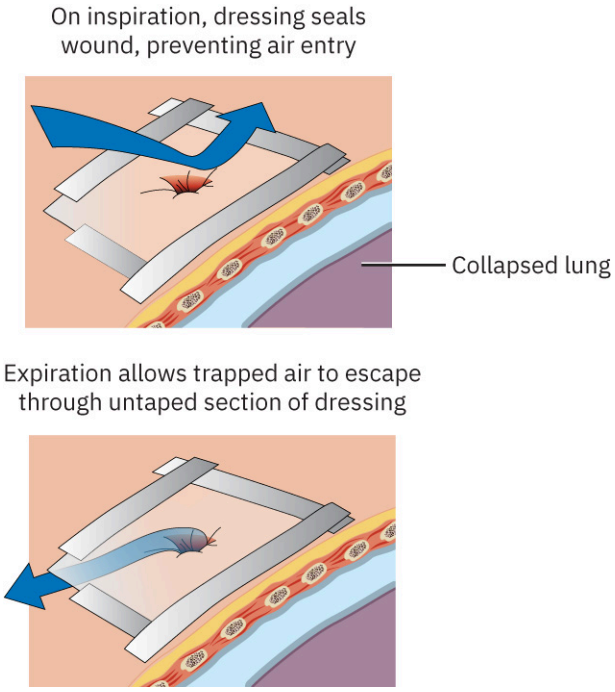

FIGURE 11.26 In the event the tube gets dislodged, creating an opening by only taping down three slides provides an exit for the trapped air to exit the puncture wound, rather than collected in the pleural space, worsening the pneumothorax. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Some patients may require surgical intervention. Surgical treatment may be indicated in a patient with recurrent pneumothorax, bilateral pneumothoraxes, or in cases where the pneumothorax has not resolved after seven days of treatment. Patients in professions that expose them to dramatic changes in barometric pressure, such as aviation or diving, may also require surgery. A surgical technique called **pleurodesis** is used to heal the break in the pleural space and can be mechanical or chemical. Mechanical pleurodesis involves abrading the parietal pleura, causing the inflammatory response to patch up the break in the pleural space. Chemical pleurodesis involves instilling chemicals into the pleural space, with the irritation creating an inflammatory response.

Because tension pneumothorax is an emergency that can result in death, immediate treatment is required to stabilize circulatory status. Tension pneumothorax is treated with **needle decompression**, where a large needle is inserted through the skin, between the ribs, into the pleural space. The large volume of air in the pleural space escapes through the needle and the lung can reexpand (McKnight & Burns, 2023).

11.7 Disorders of the Lower Respiratory System: Pneumonia and Aspiration

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for pneumonia and aspiration
- Describe the diagnostics and laboratory values in the disease of pneumonia and aspiration
- Apply nursing concepts and plan associated nursing care for the patient with pneumonia and aspiration
- Evaluate the efficacy of nursing care for the patient with pneumonia and aspiration
- Describe the medical therapies that apply to the care of pneumonia and aspiration

Pneumonia is common and affects persons without medical problems as well as persons with a variety of comorbid conditions. Pneumonia causes infections, hospitalizations, and deaths. While there are various types of pneumonia, community-acquired pneumonia (CAP) is the eighth leading cause of death in the United States. Worldwide, CAP is the leading cause of sickness and death (Ferreira-Coimbra et al., 2020). Significant mortality exists for patients hospitalized with pneumonia in the United States, at a rate of 13 percent (Ferreira-Coimbra et al., 2020).

Pathophysiology

Pneumonia is an umbrella term for a variety of infections that affect the lungs and cause inflammation (Figure 11.27). Infection can be caused by a virus, bacteria, or fungi. In aspiration pneumonia, food, fluid, upper airway

secretions, or emesis enter the trachea and respiratory tract, causing an inflammatory response (Figure 11.28). When a virus, bacteria, or fungi enters the lungs, macrophages try to eradicate the pathogen by surrounding it. This triggers inflammatory cells to travel to the infected area. Once lung tissues become inflamed, the capillaries become damaged. The affected alveoli can fill with fluid or pus, limiting the body's ability to oxygenate and ventilate.

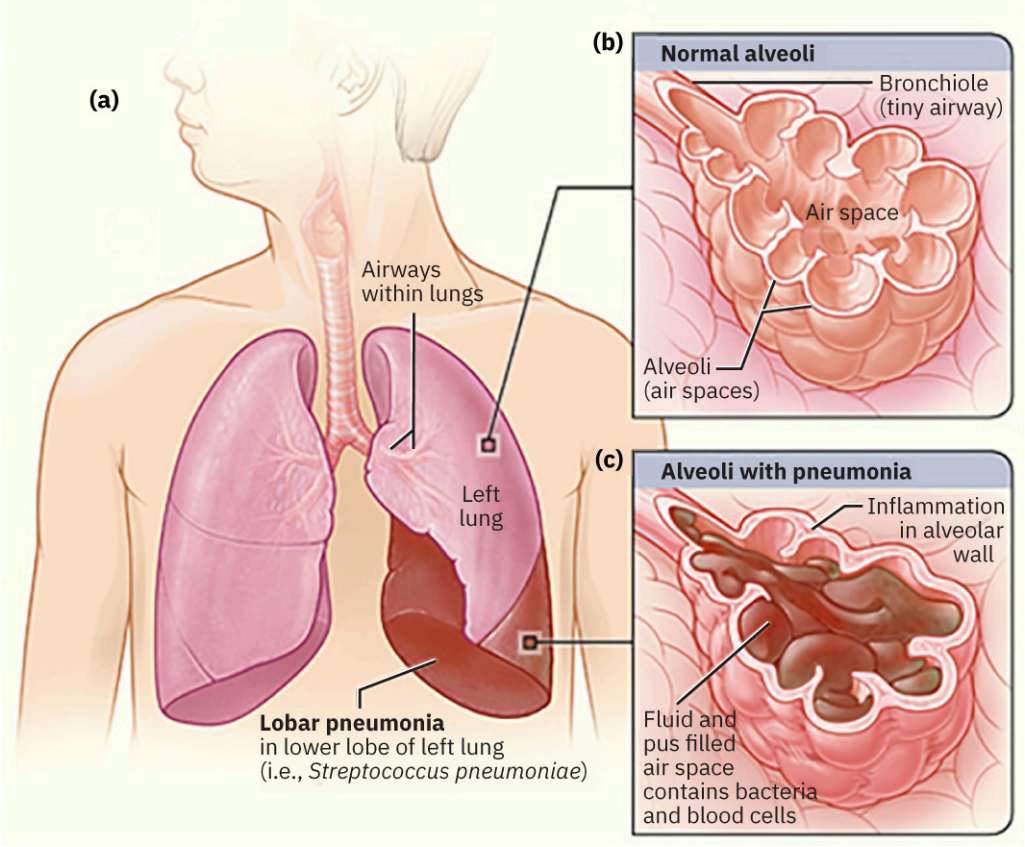

FIGURE 11.27 (a) Pneumonia may cause inflammation in all or a portion of the lungs. (b) Healthy lungs are not swollen and have adequate open air space. (c) Pneumonia causes inflammation in lung tissue and the air space can become filled with fluid. (credit: "Pneumonia, caused by bacteria." by NIH: National Heart, Lung, and Blood Institute, Public Domain)

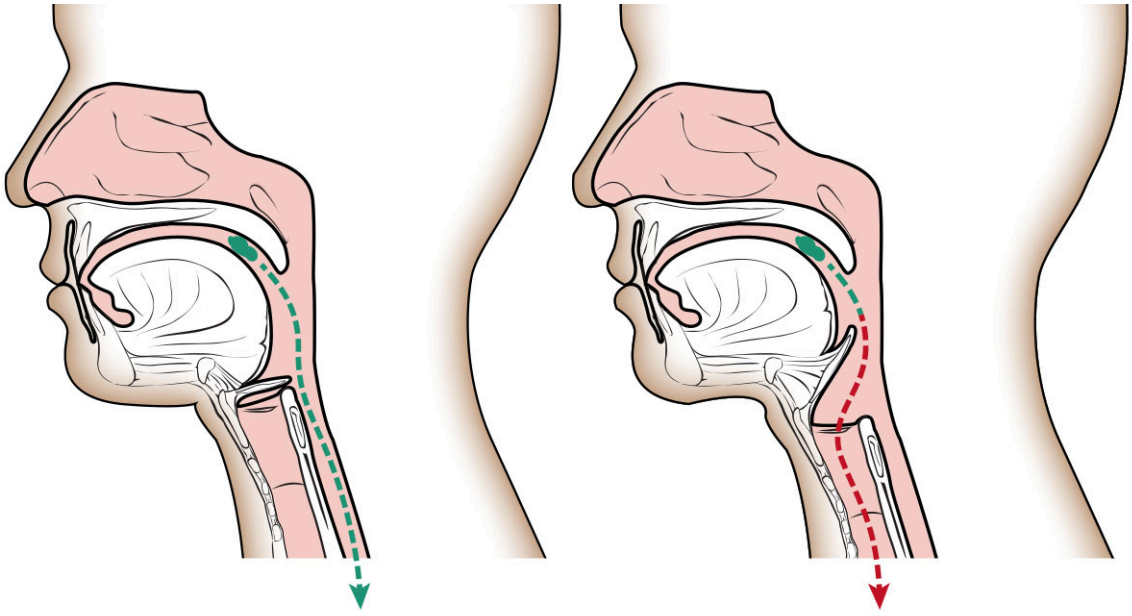

FIGURE 11.28 (a) In normal swallowing, food leaves the oral cavity and enters the esophagus. (b) In aspiration, food leaves the oral cavity and enters the trachea instead of the esophagus. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

A variety of organisms can cause pneumonia. Common pathogens implicated in pneumonia are listed in Table 11.6.

Type of Pathogen	Causes
Bacteria	*Streptococcus pneumoniae* *Haemophilus influenzae* *Moraxella catarrhalis* *Staphylococcus aureus* Group A streptococci Aerobic gram-negative bacteria (e.g., klebsiella, *Escherichia coli*) Legionella *Mycoplasma pneumoniae* *Chlamydia pneumoniae* *Chlamydia psittaci* *Coxiella burnetiid*
Viruses	Influenza A and B viruses Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) Other coronaviruses (e.g., CoV-229E, CoV-NL63, CoV-OC43, CoV-HKU1) Rhinoviruses Parainfluenza viruses Adenoviruses Respiratory syncytial virus Human metapneumovirus Human bocaviruses
Fungi	Blastomyces Histoplasma Coccidioides

TABLE 11.6 Common Pathogenic Causes of Pneumonia (Jain et al., 2022; Ramirez, 2022)

When pneumonia develops in a hospital setting, it is classified as **hospital-acquired pneumonia (HAP)**. If it occurs after a ventilator is initiated, it is termed **ventilator-associated pneumonia (VAP)**. The most common organisms seen in HAP and VAP are *pseudomonas aeruginosa, Escherichia coli, staphylococcus aureus, enterobacter,* and a*cinetobacter* (Jain et al., 2022).

Risk Factors

A variety of risk factors can increase the risk of pneumonia. These can include demographic factors as well as comorbid conditions. Pneumonia disproportionately affects patients who are under-resourced and face high poverty rates. Environmental factors, like crowded living conditions (e.g., areas with high poverty rates, prisons, shelters) and exposure to toxins like gasoline and certain paints also increase the likelihood of CAP. Older adults, persons who smoke, and persons living with lung disease, cardiac problems, diabetes, and immunosuppression are all at increased risk for severe illness and death. A diagnosis of COPD is the most significant risk factor for hospitalization with pneumonia (Jain et al., 2022; Ramirez, 2022). More specifically:

- Adults older than age sixty-five, compared with the general population, are three times more likely to be hospitalized with CAP.
- Chronic lung disease, especially COPD, significantly increases the likelihood of pneumonia.
- Viral infections can cause viral pneumonia and increase the risk of secondary bacterial pneumonia.
- All immunocompromised patients are at higher risk of pneumonia when compared with the general population; this is especially true about fungal pneumonias.
- Patients with aspiration due to dysphagia, anesthesia, or drug and alcohol use are at high risk of developing pneumonia.
- Smoking, heavy alcohol use, and opioid use increase the risk of pneumonia.
- Comorbid conditions, including chronic heart disease, malnutrition, and diabetes, increase the likelihood of severe infection.

- Socioeconomic factors, including poverty, crowded living conditions, and exposure to toxins, all increase the risk of pneumonia (Jain et al., 2022; Ramirez, 2022).

When providing care to patients with pneumonia, clinicians need to be able to identify which patients are likely to require hospital admission. An evidence-based severity score called CURB-65 uses several different criteria to assess pneumonia patients and predict need for hospitalization (Table 11.7).

	Description	Points
C	Confusion	1
U	Uremia: blood urea nitrogen > 7 mmol/L (20 mg/dL)	1
R	Respiratory rate: ≥ 30 breaths/minute	1
B	Blood pressure: systolic < 90 mmHg or diastolic < 60 mmHg	1
65	Age ≥ 65 years	1

Score of 0 or 1: Outpatient management is typically adequate.
Score of 2 or 3: Hospital admission is generally recommended.
Score of 4 to 5: ICU admission is recommended.

TABLE 11.7 **CURB-65 Pneumonia Severity Score** (Jain et al., 2022)

Clinical Manifestations

Many patients with pneumonia will display signs of systemic infection, such as fatigue, fever, chills, muscle pain, and decreased appetite. A cough is common and may be productive of yellow, green, brown, or blood-tinged sputum. Many patients with pneumonia will experience dyspnea. Some patients will demonstrate altered mental status, chest pain, or abdominal pain.

Vital sign abnormalities can include increased respiratory rate, fever, tachycardia, and decreased oxygen level. Lung auscultation can reveal crackles or decreased breath sounds. In severe cases, patients will demonstrate signs of respiratory distress, such as accessory muscle usage, nasal flaring, and difficulty speaking (Jain et al., 2022).

Assessment and Diagnostics

Diagnostic testing for pneumonia can utilize a variety of modalities. Imaging and laboratory tests are utilized to diagnose pneumonia, track its severity, and identify treatable organisms. Subjective and objective data are equally assessed to determine the best plan of care for each patient.

For a conclusive diagnosis of pneumonia, imaging is required. While a chest x-ray is utilized most often, chest CT is also an option; both can demonstrate visual evidence of pneumonia. Areas of inflammation and consolidation caused by pneumonia are often identifiable as whitish areas of opacity. A complete blood count can show increased white blood cells. Viral swabs and sputum cultures are done to identify the responsible organism so appropriate medications are given to the patient. When certain types of pneumonia (e.g., *legionella*) are suspected, urinary antigen testing is used. C-reactive protein and procalcitonin are used to differentiate bacterial and viral pneumonia. Lactic acid level may be checked if septic pneumonia is suspected. In severe cases, arterial blood gas analysis may indicate low oxygen levels. To evaluate patients with potential VAP, bronchoscopy may be used. A thin tube called a **bronchoscope** is inserted into the mouth or nose and a camera allows visual examination of lung tissue. The bronchoscope can obtain biopsy samples and treat blockages. In VAP patients, using a bronchoscope to obtain a sample can identify the organism to treat (Figure 11.29) (Jain et al., 2022).

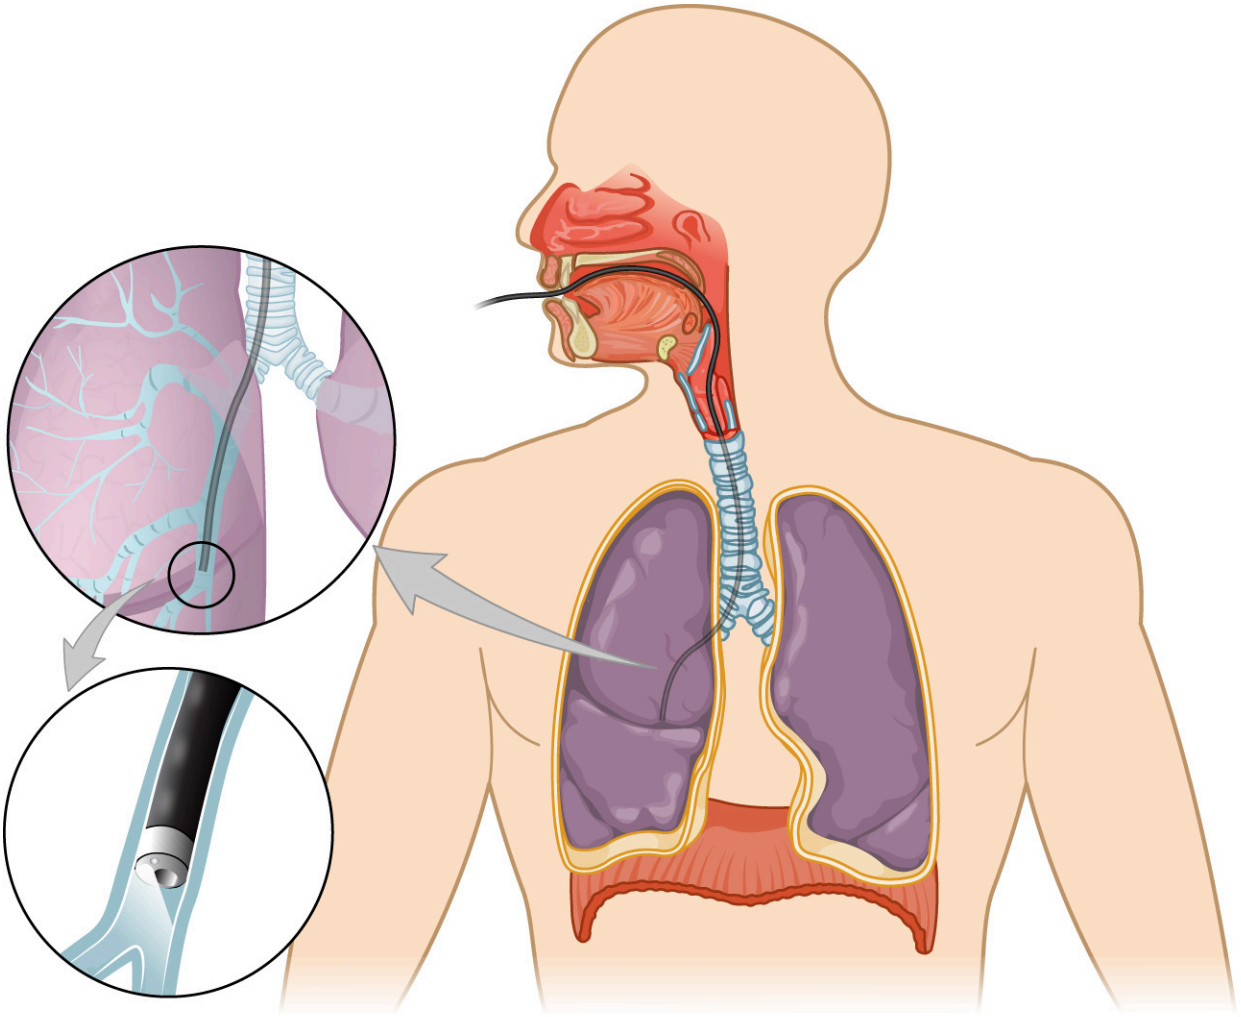

FIGURE 11.29 A thin tube called a bronchoscope is inserted into the mouth or nose. A camera allows visual examination of lung tissue. The bronchoscope can obtain biopsy samples and treat blockages. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Nursing Care of the Patient with Pneumonia and Aspiration

While pneumonia is common and often easily treatable, there is the potential for life-threatening illness. Close monitoring and timely intervention can, in many cases, prevent complications.

Recognizing Cues and Analyzing Cues

The nurse caring for a patient with suspected or confirmed pneumonia considers patient-reported data as well as objective assessment findings. Self-reported symptoms may include cough, dyspnea, and general signs of systemic infection. Purulent or blood-tinged sputum can occur with bacterial pneumonia. Sputum associated with viral pneumonia is often watery, though occasionally contains both mucus and pus (Jain et al., 2022). Understanding the patient's medical history is essential, especially any known lung diseases, neurological insult, such as stroke, cardiac problems, diabetes, and being immunocompromised. Objectively, vital signs are evaluated with a focus on respiratory rate and oxygen saturation. Fever and tachycardia may be present. Lung auscultation may reveal crackles or diminished breath sounds in some lung fields. The nurse identifies if breathing is labored or unlabored.

CLINICAL SAFETY AND PROCEDURES (QSEN)

QSEN Competency: Safety

Disclaimer: Always follow the agency's policy for medication administration.

Definition: Minimizes risk of harm to patients and providers through both system effectiveness and individual performance. The nurse will...

Skill: Demonstrate effective strategies to reduce the risk of harm to self or others.

Attitude: Value the contributions of standardization/reliability to safety. Patients suspected of having pneumonia should be made NPO right away, until cleared by a provider, because one of the major complications is aspiration pneumonia leading to additional infections.

- The patient should remain NPO until a trained provider or speech pathologist can perform a swallow screen using an evidence-based tool.
- Swallow should be evaluated before any PO food, fluids, or medications are given to identify dysphagia and prevent aspiration.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

In patients with pneumonia, signs of respiratory distress and decreased oxygenation are the highest priority. The nurse will monitor vital signs, administer oxygen, or prepare a patient for imaging and/or procedures. A decreased oxygen level, increased respiratory rate, signs of labored breathing, and alterations in mental status are all signs that supplemental oxygen (and possibly ventilation) is urgently required. Medication administration may include antibiotics, antiviral medications, or bronchodilators. Instruction on energy conservation and pacing can be helpful as patients recover. Due to the possibility of spread via droplet or airborne particles, PPE is often indicated when providing care to patients with pneumonia.

CLINICAL SAFETY AND PROCEDURES (QSEN)

Evidence-Based Practice: Strategies to Prevent Aspiration Pneumonia

Many cases of aspiration pneumonia can be prevented. Prevention strategies address oral hygiene and actual or potential swallowing problems.

1. Improve oral hygiene and increase access to dental care to decrease the likelihood of harmful bacteria in the oral cavity.
2. In hospitalized patients, assist with toothbrushing, denture care, and routine oral care. This may include suctioning out excess saliva, swabbing the mouth with moisturizer, and applying lip balm.
3. When aspiration risk is related to swallowing problems, collaborate with speech-language pathologists for expert guidance on strategies for safe swallowing.
   - An upright position (at least 30 degrees), appropriate head position, and maintaining an upright position after eating can decrease the risk.
   - Many patients will benefit from a slow pace while eating and drinking.
   - Some patients will require a specialized diet with textures that decrease the risk of aspiration.
4. When feeding tubes are utilized, it is important to ensure correct placement so that food, fluid, and medications do not inadvertently enter the respiratory tract.
5. For planned procedures requiring anesthesia, preprocedure fasting is suggested (Texas Health and Human Services).

Evaluation of Nursing Care for the Patient with Pneumonia and Aspiration

With skilled interprofessional care, most patients with pneumonia will recover well. Close assessment during the recovery period provides information about illness trajectory and need for ongoing treatment. The most important outcomes related to pneumonia center on resolution of respiratory symptoms. The nurse monitors pulse oximetry, oxygen requirement, and lung sounds. Signs of infection are evaluated, including temperature, white blood count, and sputum production. Patient-reported symptoms to reevaluate include dyspnea, cough, fatigue, fever, and chills. Repeat imaging may be required to identify if pneumonia is improving or has resolved.

LIFE-STAGE CONTEXT

Gerontological Considerations

When caring for older adults, the nurse must consider various gerontologic considerations to ensure optimal outcomes. Age-related changes, such weaker immune systems, make them more prone to developing pneumonia. The older adult populations have more comorbidities to consider, such as previous strokes, decline in cognition, and Parkinson's disease and dementia. These contribute to a higher probability of aspiration, which can lead to aspiration pneumonia. Older adults with identified risks for aspiration should have nursing interventions implemented to reduce these risks. The primary methods used to prevent aspiration during oral intake include:

- Referral for a swallow study
- Texture modification of food/liquids
- Positional swallowing maneuvers, such as chin-tuck
- Thickened liquids

Older adults are also at an increased susceptibility to increased risk of infection, due to lower immunity thresholds, all of which necessitate a tailored approach to the older population.

Medical Therapies and Related Care

Medical therapy varies based on the severity of illness (Table 11.8). When community-acquired pneumonia occurs, oral antibiotic therapy is usually utilized. A stronger antibiotic may be needed if the patient smokes or has comorbid conditions like COPD, heart disease, or diabetes. When patients are admitted to the hospital with severe pneumonia, intravenous antibiotics are often needed. Inhaled bronchodilators can be used to improve the sensation of shortness of breath. Viral pneumonia may be treated with antiviral medications, such as oseltamivir. Antifungal medications are used to treat fungal pneumonias.

Severity of Pneumonia	Appropriate Therapy
CAP, CURB-65 score 0 to 1	If adverse comorbidities are present: fluoroquinolones or beta-lactams plus macrolides If no adverse comorbidities are present: macrolides or doxycycline
CAP, CURB-65 score 2 to 3	Fluoroquinolones or macrolides plus beta-lactams
CAP, CURB-65 score 4 to 5	Beta-lactams plus fluoroquinolones or beta-lactams plus macrolides
VAP & HAP	Broad-spectrum antibiotics: • For patients without risk factors for multidrug resistance: piperacillin/tazobactam plus cefepime plus levofloxacin • For patients with risk factors for multidrug resistance: combination of an aminoglycoside plus one of the following: imipenem, meropenem, aztreonam, piperacillin/tazobactam, ceftazidime, or cefepime

TABLE 11.8 Antimicrobial Therapy for Pneumonia (Jain et al., 2022)

In many cases, hospitalized patients will require supplemental oxygen. In severe cases, ventilatory support may be needed. This can be noninvasive (e.g., BiPAP) or invasive (e.g., ventilator) (Figure 11.30). Bilevel positive airway pressure, or **BiPAP**, can provide breathing support to patients in respiratory distress. A tight-fitting mask goes over

the nose and/or mouth, and the attached machine blows air into the airway. Bilevel means there are two pressure settings: inhalation positive airway pressure (IPAP) and exhalation positive airway pressure (EPAP). BiPAP can increase oxygen levels and lower carbon dioxide levels. The care of a patient with pneumonia can be complex. It involves close collaboration between physicians, nurses, respiratory therapists, pharmacists, and radiologists (Ramirez, 2022).

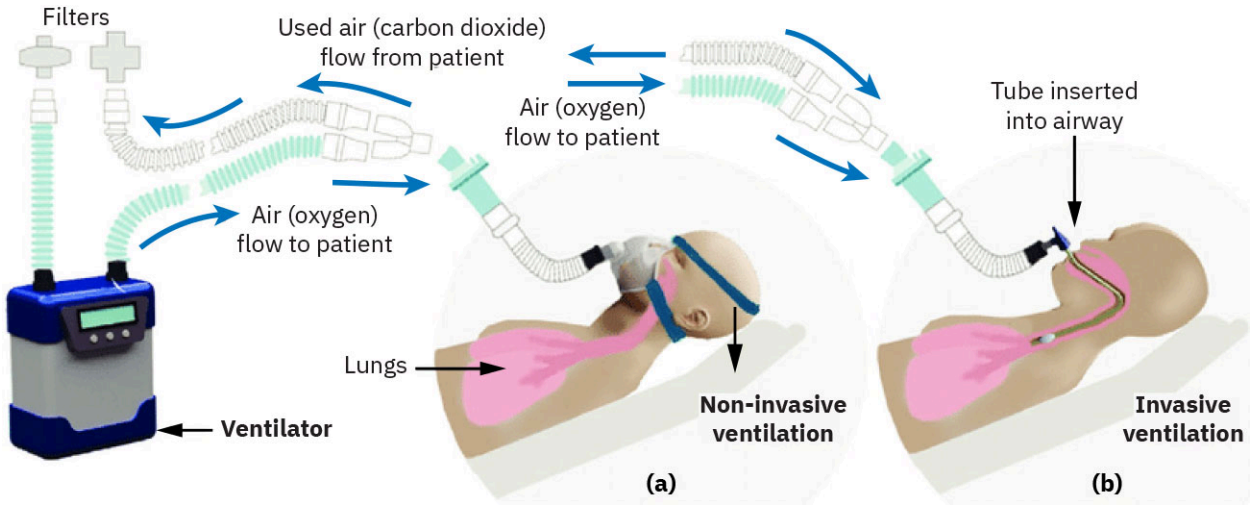

FIGURE 11.30 A ventilator is a machine that is used to support breathing. It delivers oxygen and removes carbon dioxide. Additionally, it can provide pressure to maintain open airways. Tubes from the machine connect to (a) a tight-fitting mask (noninvasive ventilation) or (b) a breathing tube in the trachea (invasive ventilation). 11.8 Disorders of the Lower Respiratory System: Tuberculosis

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for tuberculosis
- Describe the diagnostics and laboratory values in the disease of tuberculosis
- Apply nursing concepts and plan associated nursing care for the patient with tuberculosis
- Evaluate the efficacy of nursing care for the patient with tuberculosis
- Describe the medical therapies that apply to the care of tuberculosis

While the prevalence of tuberculosis is lower in the United States than in many other countries, more than 1.7 billion people worldwide are estimated to be infected. With 22 percent of the world's population infected with tuberculosis, it is impossible to overstate the burden of disease and global suffering. India, Sub-Saharan Africa, and the islands of Southeast Asia experience the highest rates of infection, with a rate of 300 cases per 100,000. In the United States, tuberculosis infects less than 25 persons per 100,000. Global poverty, including lack of access to adequate health care and clean water, accounts for this disparity (Horsburgh, 2024).

LINK TO LEARNING

Dr. Paul Farmer was a pioneering physician and medical anthropologist who died suddenly in 2022. He cofounded an organization called Partners in Health (https://openstax.org/r/77PartnerHealth) that is focused on providing high-quality health care to people worldwide in underserved areas.

Pathophysiology

Tuberculosis is caused by the airborne bacterium *Mycobacterium tuberculosis* (*M. tuberculosis*). Tiny particles called **droplet nuclei** are expelled from an infected person during talking, coughing, or singing, and these droplets remain airborne for several hours. While airborne, the infectious particles can be inhaled by others, eventually reaching the alveoli. After exposure, not everyone is infected with tuberculosis. Several factors impact the likelihood of infection:

- immune status of the person who is exposed
- how infectious the ill person is
- environmental factors (e.g., small spaces, inadequate ventilation, recirculation of infectious air)
- proximity, length, and frequency of exposure

Once inhaled, the droplet nuclei bring the tubercle bacilli to the lungs, where they eventually reach the alveoli. Macrophages ingest the tubercle bacilli, damaging and destroying many of them. In some cases, the body will clear the initial infection. In other cases, the initial infection persists but becomes latent. The tubercle bacilli become walled off into a capsule called a **granuloma**, which prevents spread.

Often, the initial infection will become reactivated, causing the tubercle bacilli to spread to other locations within the lung. Again, the body attempts to control the infection by encasing the tubercle bacilli in a granuloma. During widespread infection, however, this becomes problematic. Granulomas can develop cavities. They are filled with a lipid-rich substance, which can accelerate the spread throughout the lungs and body via the lymphatic or circulatory systems. Distant TB disease is most likely to develop in the brain, bone, kidneys, regional lymph nodes, and the uppermost part of the lungs.

LINK TO LEARNING

Watch this short video from the series *Rx for Survival*, entitled "An Incurable TB?" (https://openstax.org/r/77IncurableTB) to learn more about TB.

Risk Factors

In the United States, major risk factors include immunosuppression (including HIV), substance abuse, and malnutrition. Due to TB spreading by close contact, the risks of TB infection increase in high-density living situations, including incarceration and other congregate living settings. Structural poverty diminishes access to health care, so increased rates of infection occur among under-resourced populations. Significant disparities in infection rates exist when comparing demographic groups in the United States, as shown in (Table 11.9).

Demographic Group	Disease Incidence per 100,000
Asian	21.7
Black	15.3
Hispanic	8
White	2.8

TABLE 11.9 Variations in TB Infection Rates across Ethnic Groups
(CDC, 2021; Horsburgh, 2024)

Clinical Manifestations

Patients with active TB infection typically present with systemic symptoms. These can include fever, chills, night sweats, weight loss, weakness, fatigue, and decreased appetite. A chronic cough, lasting longer than three weeks, can be present, along with bloody or purulent sputum. Patients may also report shortness of breath and pleuritic chest pain. Lung sounds may be decreased or demonstrate crackles or wheezing (Loddenkemper et al., 2016).

Assessment and Diagnostics

Accurate assessment and diagnosis of TB is necessary so that infection prevention strategies and treatment can be initiated promptly. There are two types of laboratory tests that can test for TB: a blood test and a skin test. The utility of both blood and skin tests is limited because they are unable to differentiate an active infection from a latent one. An additional challenge related to skin testing is that false positives can occur when people have received a certain type of TB vaccine; additional screening is necessary to conclusively determine TB status.

Imaging is often used to identify abnormal areas of the lungs. Chest x-ray is most often utilized although CT scan can also be used. While abnormalities that look like TB, such as cavitary lesions, can be identified on imaging, it does not confirm a diagnosis. The conclusive way to diagnose TB is by obtaining a sputum sample and examining it for the presence of tubercle bacilli. When evaluating a complete blood count, elevated platelets, elevated white blood cells, and anemia may be present (CDC, 2021).

Nursing Care of the Patient with TB

Nursing care of the patient with TB begins with screening, symptom assessment, and infection prevention. Diagnostic imaging and medication administration are additional key components.

Recognizing Cues and Analyzing Cues

The nurse caring for a patient with suspected or confirmed TB understands that TB is a highly infectious disease, which merits priority interventions and actions. The nurse evaluates both subjective and objective data. Self-reported symptoms may include fever, chills, night sweats, weight loss, weakness, fatigue, and decreased appetite. Many patients with TB will report a chronic cough, lasting longer than three weeks, along with bloody or purulent sputum. Patients may report shortness of breath, and **pleuritic** chest pain can occur; this type of pain is severe, sudden, and happens with inhalation and exhalation. Patients describe it as burning, stabbing, or sharp. The nurse should also ask the patient about any recent travel or potential exposure. Objectively, vital signs are evaluated with a focus on respiratory rate and oxygen saturation. Lung auscultation may reveal decreased lung sounds, crackles, or wheezing (Loddenkemper et al., 2016).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

In patients with suspected or confirmed TB, prevention of the spread of the infection is a high priority. The nurse should facilitate placement into a negative airflow private room. If a negative airflow room is not available, the patient should always wear a surgical mask and be moved to a location away from others. Necessary staff require personal protective equipment (PPE), including a respirator that has been fit tested for each individual. The nurse may need to monitor vital signs, prepare a patient for imaging, or administer medications. Coaching about the importance of medication compliance is crucial. Instruction on strategies to minimize the risk of transmission at home is important. These include isolating when possible, sleeping alone, avoiding visitors, and covering nose and mouth with sneezing and coughing (CDC, 2021).

Evaluation of Nursing Care for the Patient with TB

Evaluation of nursing care for patients with TB requires a focus on symptom assessment, treatment efficacy, and potential infection transmission. Initial and follow-up imaging is often needed. The most important outcomes related to TB treatment are ensuring the patient's continued cooperation with the medication regimen, preventing spread of infection during treatment, and continuing treatment until a definitive cure is achieved. An additional treatment goal is to prevent the development of disseminated tuberculosis, where mycobacteria has spread to distant body parts. Additionally, the nurse may assess for any changes in symptoms, such as worsening cough and night sweats. Repeat imaging may be ordered to determine if TB is improving, worsening, or plateaued (CDC, 2021).

Medical Therapies and Related Care

TB generally requires at least six months of treatment. Most of the bacteria are eradicated within the first eight weeks of treatment, but persistent organisms can remain and must be treated to prevent ongoing illness, infectious spread, and antibiotic resistance. The four main TB treatment drugs are isoniazid, rifampin, ethambutol, and pyrazinamide; a four-drug regimen is used (Table 11.10). With appropriate treatment, virtually all patients can be cured. Because TB is disproportionately prevalent in under-resourced areas, inadequate treatment can occur due to medication and staff shortages. This can result in ongoing infections and drug resistance. To help patients complete the long treatment regimen, many treatment centers offer in-person or electronic directly observed therapy (DOT).

Drug Class	Medication
First-line drugs	Isoniazid (INH)
	Rifampin (RIF)
	Pyrazinamide (PZA)
	Ethambutol (EMB)
	Rifabutin (RBT)*
	Rifapentine (RPT)
Second-line drugs	Streptomycin (SM)
	Cycloserine
	Capreomycin
	ρ-Aminosalicylic acid
	Levofloxacin*
	Moxifloxacin*
	Gatifloxacin*
	Amikacin/Kanamycin*
	Ethionamide

TABLE 11.10 Medications Currently Used to Treat TB in the United States *Not approved by the U.S. Food and Drug Administration for the treatment of TB (CDC, 2024)

Because the burden of treatment is so complex, collaborative care is crucially important. Successful care of a patient with TB may involve physicians, nurses, laboratory scientists, pharmacists, social workers, and respiratory therapists. Each interdisciplinary team member is assigned a portion of the directly observed therapy short course plan.

11.9 Disorders of the Lower Respiratory System: Cystic Fibrosis

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for cystic fibrosis
- Describe the diagnostics and laboratory values in the disease of cystic fibrosis
- Apply nursing concepts and plan associated nursing care for the patient with cystic fibrosis
- Evaluate the efficacy of nursing care for the patient with cystic fibrosis
- Describe the medical therapies that apply to the care of cystic fibrosis

Cystic fibrosis (CF) is an inherited disease caused by a gene mutation. This mutation impacts how sodium and chloride ions travel across cell membranes. As a result, thick mucus accumulates in the lungs and throughout the body. Serious breathing problems and other physical issues occur. In the United States, more than 30,000 people are affected by CF. It is most common in White persons and especially persons of Northern European descent. In

those populations, about one in 3,500 births is affected. CF is caused by a mutation affecting the CF transmembrane conductance regulator (CFTR) gene. Some people carry the gene but do not develop CF. Because of treatment advances, life expectancy has climbed for patients with CF. Currently, the median survival age for patients with CF is forty. While the pulmonary implications of CF are the primary cause of illness and death, it does affect other organ systems. There is a major treatment burden associated with CF, and recurrent hospitalizations are common (Brown et al., 2017; Karakashian et al., 2021).

Pathophysiology

CF is an inherited disease caused by a mutation in the CFTR gene. Because of the mutation, changes occur that affect how sodium and chloride ions move across cell membranes. When this movement is impaired, thick mucus builds up in the lungs and throughout the body (Figure 11.31). This causes breathing problems and affects other body systems. The thick mucus creates an optimal environment for bacterial colonization. Common infections include pseudomonas, *Haemophilus influenza*, and *staphylococcus aureas*. A person with CF experiences a major inflammatory response to the infection. Over time, the repeated cycles of infection and inflammation destroy parts of the airways.

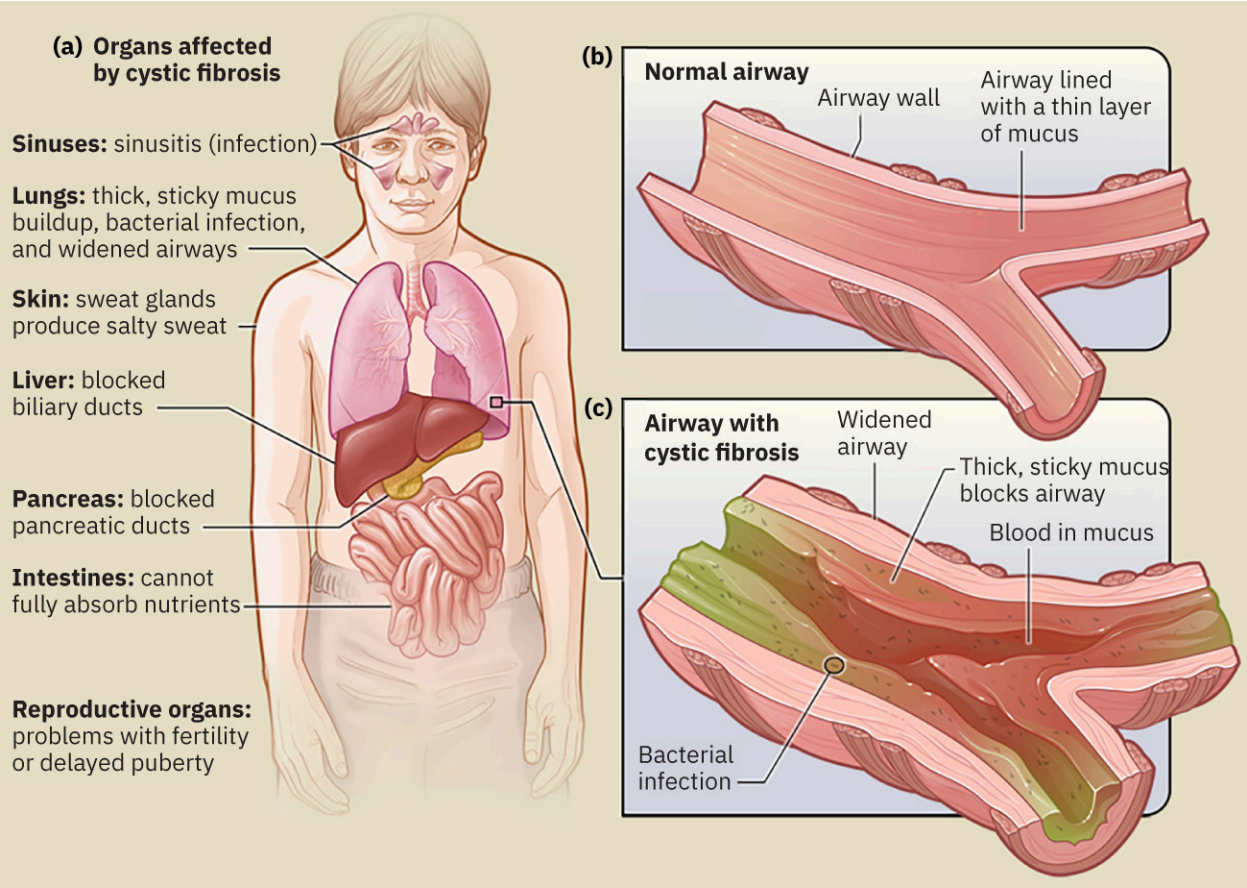

FIGURE 11.31 (a) There are lung problems associated with cystic fibrosis that occur due to mucus in the airways. Patients with cystic fibrosis also experience impacts to other body systems. (b) In a normal airway, the walls are lined with a thin layer of mucus. (c) The airway in CF is widened and filled with thick, sticky mucus. (credit: "How cystic fibrosis affects the body." by NIH: National Heart, Lung, and Blood Institute, Public Domain)

Risk Factors

Because CF is an inherited disease, family history is the primary risk factor. If both parents carry the gene mutation, their offspring will have a one in four chance of developing CF and a one in two chance of becoming a carrier (Brown et al., 2017; Karakashian et al., 2021).

Signs and Symptoms/Clinical Presentation

Most people will be diagnosed with CF before age two when there are not yet obvious manifestations. Observable symptoms usually affect the gastrointestinal system first. Symptoms can manifest at birth; a neonate may present

with an ileus from their first stool (**meconium**). Children may have a chronic cough, wheezing, and GI malabsorption. This can result in failure to thrive, growth restrictions, small stature, and decreased weight gain. Additional GI symptoms can include abdominal bloating, fatty stools, constipation, volvulus, intussusception, and biliary cirrhosis. Respiratory symptoms can include recurrent pneumonia, hemoptysis, shortness of breath, bronchiolitis, nasal polyps, and bronchiectasis. Over time, digital clubbing and increased anterior/posterior chest diameter can occur. Genitourinary symptoms associated with CF include decreased fertility, sterility, undescended testes, and congenitally absent vas deferens (Brown et al., 2017; Karakashian et al., 2021).

Assessment and Diagnostics

Timely diagnosis of CF is critical to ensure prompt access to treatment and care. Effective screening guidelines have been implemented. In the United States, all newborns are screened at birth for CF using a heel stick blood test. The average age at diagnosis is six to eight months and most patients are diagnosed prior to age two. If the initial blood test is positive, a **sweat test** is used for conclusive diagnosis. During a sweat test, a chemical and a small amount of electrical stimulation are applied to the skin to encourage sweat production. Over the course of thirty minutes, sweat is collected and sent to the lab for analysis. Elevated levels of sodium and chloride in the sweat confirm a diagnosis of CF. When an infection is suspected, a sputum culture and Gram stain can identify the organism so targeted treatment can be initiated. Liver function tests may show elevated results. A seventy-two-hour stool test can evaluate the presence of fecal fat and show increased fat and decreased albumin.

Imaging, most commonly chest x-ray, is used to assess disease progression and evaluate exacerbations. Pulmonary function testing is used to quantify disease progression and the severity of exacerbation. Arterial blood gas analysis can demonstrate hypoxemia and abnormally low blood pH. These results can support the initial diagnosis as well as provide information on disease progression (Brown et al., 2017; Karakashian et al., 2021).

Nursing Care of the Patient with CF

Nursing care of a patient with CF occurs across the life span, typically starting in childhood. While respiratory manifestations are prevalent, other body systems are also affected.

Recognizing Cues and Analyzing Cues

The nurse caring for a patient with suspected or confirmed CF evaluates both subjective and objective data. Prior to diagnosis, it is important to understand family history and known risk of inherited disease. The nurse assesses the patient and caregiver's stress and emotional well-being as they face a chronic disease. In an infant, meconium ileus may be present. Parents may note salty sweat, gastrointestinal problems, or a chronic cough. In a patient with known CF, the nurse asks about difficulty breathing, secretions, and cough. Because CF is a systemic disease that affects more than the lungs, it is important to assess for gastrointestinal symptoms, such as bowel obstruction, malabsorption, and pancreatic insufficiency. Objectively, vital signs are evaluated with a focus on respiratory rate, oxygen saturation, and temperature. Lung sounds may demonstrate crackles or wheezing (Karakashian et al., 2021).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

In patients with CF, respiratory status is a high priority. The nurse may need to monitor vital signs, prepare a patient for imaging, or administer medications. Medications may be oral, intravenous, or inhaled. Antibiotics are commonly needed. Many patients with CF will require supplemental oxygen. Gastrointestinal interventions may include evaluating food intake, administering pancreatic enzymes and salt tablets, and supporting bowel function. To improve airway clearance, collaboration with respiratory therapy (and sometimes physical therapy) is necessary. When patient and caregiver stressors are present, the nurse prioritizes their emotional well-being and coping skills by facilitating access to resources like support groups, financial assistance, and mental health counseling (Karakashian et al., 2021).

Evaluation of Nursing Care for the Patient with CF

Nursing care for patients with CF centers on managing secretions, airway clearance, and prevention and treatment of exacerbations. Evaluation considers patient history, physical assessment, and physiologic parameters. The most important outcomes related to CF are airway clearance, prevention of exacerbation, and increased life expectancy. Patient reporting, lung auscultation, direct observation of cough, and vital sign assessment can provide important information about airway clearance status and signs of exacerbation. Adequate hydration, nutrition, and elimination

are important outcomes to monitor (CDC, 2021; Karakashian et al., 2021).

Medical Therapies and Related Care

The treatment of CF is complex and ongoing. Effective care requires close collaboration between the patient, caregivers, physicians, nurses, respiratory therapists, pharmacists, and rehabilitation therapists. Preventive care includes vaccination for preventable respiratory illnesses. Airway clearance therapy is necessary to help patients clear the thick, tenuous airway secretions. This can include manual chest percussion, a wearable high-frequency vest that delivers compression (Figure 11.32), flutter valve therapy, and mechanical ventilation. Inhaled medications, such as hypertonic saline and dornase alfa, can thin secretions, making it easier for mucus to be cleared. In children under eighteen, high-dose ibuprofen is utilized; studies have demonstrated that it decreases loss of lung function. When exacerbations occur, corticosteroids decrease inflammation and inhaled bronchodilators decrease airway hyperresponsiveness. Antibiotics are used during active infections and sometimes as prophylaxis. Some patients will be candidates for a lung transplant, which can extend life span by about five years in children and eight years in adults.

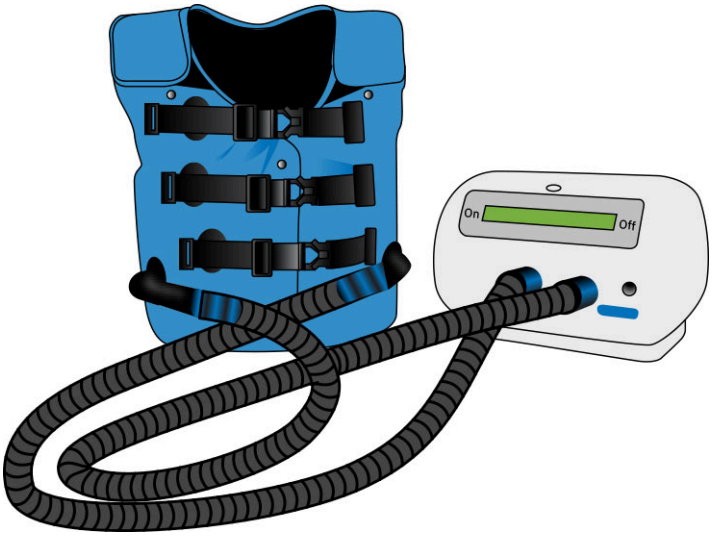

FIGURE 11.32 To help remove thick mucus, a patient with CF may use a wearable vest connected to a machine. A compressor rapidly sends air into and out of the vest through hoses. The vibrations and pressure can break up thick secretions, making it easier for the patient to clear them. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Because the gene mutation affects organs other than the lungs, additional treatment is required. Many patients with CF will experience digestion problems related to pancreatic insufficiency and require **pancreatic enzymes** supplementation as part of their treatment. In most male patients, the vas deferens is absent, but the body still produces sperm. In patients who want to consider reproduction, sperm can be harvested and used for assisted conception.

11.10 Effects of Smoking, Vaping, and Environmental Triggers of the Respiratory System

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the effects of smoking, vaping, and environmental triggers of the respiratory system
- Apply nursing concepts and plan associated nursing care for the patient who smokes, vapes, or has environmental triggers of respiratory illness
- Evaluate the efficacy of nursing care for the patient who smokes, vapes, or has environmental triggers of respiratory illness

Worldwide, cigarette smoking causes over seven million deaths every year. New tobacco products, e-cigarettes, became available around 2007 and rapidly gained popularity. Today, millions of Americans, including adolescents, use e-cigarettes (“vape”). Despite known health risks, this profitable industry continues to use marketing and advertising to promote cigarettes and **vaping**. Due to the novelty of e-cigarettes, long-term data to illustrate the

consequences and trajectory of use is not available.

Pathophysiology of Smoking and Vaping

The pathophysiology of cigarette smoking affects virtually every body system. Tobacco smoke contains about sixty known carcinogens. Research suggests that these carcinogens damage DNA, causing mutations that lead to tumor formation. When tobacco smoke is inhaled, it causes an inflammatory state in the lungs and increases the number of free radicals in the body. Increased oxidative stress leads to problems with dilation and constriction of blood vessels, increased blood clot risk, and increased inflammation. This can cause serious coronary artery disease (Adams & Morris, 2022). Smoking is a primary risk factor for developing COPD. Lung damage results in elevated CO_2, low oxygen levels, and vasoconstriction.

In vaping, the e-cigarette heats up a solution, which vaporizes and can be inhaled. This solution can contain nicotine, tetrahydrocannabinol (THC), butane hash oils, and cannabidiol, as well as other additives. The vaporization process turns the solution into ultrafine particles, allowing volatile organic compounds and heavy metals to be inhaled. Some of the additives decompose into dangerous compounds (e.g., formaldehyde). Similar to cigarette smoking, these compounds have been linked to oxidative stress, inflammation, emphysema, and increased cardiovascular risk (Perkins, 2020).

Clinical Manifestations of Chronic Effects from Smoking and Vaping

Smoking and vaping both carry a risk of causing severe health problems for patients. The danger may feel abstract to patients because noticeable problems may not occur for months or years.

Assessment and Diagnostics

Chronic smoking can cause many clinical symptoms and conditions. Some patients may smoke heavily for years before encountering symptoms. Chronic cough, dyspnea, hypoxia, and development of COPD are common. Smoking is linked with many other lung conditions (e.g., pulmonary fibrosis) and can exacerbate asthmatic symptoms. Many diagnostic tests are used to evaluate respiratory problems related to smoking. Imaging can include chest x-ray, CT scan, and ultrasound. The lungs can be directly visualized and biopsied by using bronchoscopy. Pulmonary function testing can be used to evaluate lung function.

Patients who use e-cigarettes can develop EVALI (e-cigarette or vaping use-associated lung injury). This can cause chest pain, bloody sputum, fever, cough, headache, muscle aches, fatigue, and shortness of breath. EVALI can result in life-threatening complications, including hemorrhage, pneumonia, acute lung injury, and pneumothorax. In addition, they can develop **pleural effusion**, a serious consequence that impacts breathing due to fluid accumulated in the pleural space and **acute respiratory distress syndrome (ARDS)**, a potentially fatal complication. As a result of lung injury, fluid builds up in the lungs, oxygen levels drop, and scarring can occur. Vital sign changes include increased respiratory rate and decreased oxygen level. Because these symptoms are nonspecific and can occur with many diseases, EVALI is considered a diagnosis of exclusion. Diagnostic tests will include chest x-ray, CT scan, bronchoscopy, and influenza screening (Perkins, 2020).

Smoking is linked to approximately 90 percent of lung cancer cases and is the most significant risk factor. The U.S. Preventive Services Task Force currently recommends that certain smokers undergo periodic low-dose CT screening to evaluate for lung cancer. When lung cancer is caught at an early stage, treatment is more likely to be effective. Annual CT screening is recommended for adults between the ages of fifty to eighty, with a twenty pack-year smoking history, who smoke currently, or quit sometime in the last fifteen years (U.S. Preventive Services Task Force, 2021).

Nursing Care of the Patient Who Smokes and/or Vapes

In both the near- and long-term, smoking and vaping can have serious consequences for patients. Nursing care aims to stabilize the immediate situation and provide resources to mitigate future complications. Cessation strategies and support are central aspects of nursing care.

Recognizing Cues and Analyzing Cues

Accurately understanding a patient's smoking history is important. The nurse should ask how many packs or cartridges per day the patient consumes, and how many years they have smoked. The nurse evaluates subjective and objective data, including patient reports of cough, dyspnea, and pain. Physical assessment evaluates for

adventitious lung sounds and changes that can occur with chronic smoking-related lung disease, such as a barrel-chested appearance. Patient position can provide important information about work of breathing. Many patients struggling to breathe are unable to tolerate lying flat and instinctively assume an upright, tripod position. Vital signs are assessed with a focus on respiratory rate and oxygen saturation. Educate the patient about fire safety concerns related to cigarette or e-cigarette smoking. Traditional cigarettes have a fire risk related to the open flame; e-cigarettes also have a fire risk related to the battery.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

In patients who smoke cigarettes or vape, respiratory status is a high priority. Depending on the complication, the nurse may need to monitor vital signs, prepare a patient for imaging, or administer medications. Medications may be oral, intravenous, or inhaled. Many patients will require supplemental oxygen. Patient education around fire safety, especially for patients who use supplemental oxygen, is an important nursing action. Smoke detectors and fire extinguishers should be readily available. Smoking in the same room as oxygen is potentially life-threatening.

At a minimum, patients need to stay at least six feet from an open flame (candle, fireplace, or stove) (MedlinePlus, 2022).

Supporting patients in efforts to quit smoking is a crucial nursing action. Structured frameworks exist that can guide clinicians as they undertake this complex task. The U.S. Preventive Services Task Force recommends the 5A's approach (Table 11.11).

Intervention	Technique
Ask	Implement an officewide system that ensures that, for every patient at every clinic visit, tobacco-use status is queried and documented. Repeated assessment is not necessary in the case of the adult who has never used tobacco, or has not used tobacco for many years, and for whom this information is clearly documented in the medical record.
Advise	Strongly urge all tobacco users to quit in a clear, strong, personalized manner.
	Advice should be:
	• Clear: "I think it is important for you to quit smoking now and I can help you." "Cutting down while you are ill is not enough."
	• Strong: "As your clinician, I need you to know that quitting smoking is the most important thing you can do to protect your health now and in the future. The clinic staff and I will help you."
	• Personalized: Tie tobacco use to current health/illness and/or its social and economic costs, motivation level/readiness to quit, and/or the impact of tobacco use on children and others in the household.
Assess	Determine the patient's willingness to quit smoking within the next thirty days:
	• If the patient is willing to make a quit attempt at this time, provide assistance.
	• If the patient will participate in an intensive treatment, deliver such a treatment or refer to an intensive intervention.

TABLE 11.11 The 5As Approach to Supporting Patients in Smoking Cessation (Tobacco Use and Dependence Guideline Panel, 2008)

Intervention	Technique
	• If the patient clearly states that they are unwilling to make a quit attempt at this time, provide a motivational intervention and/or offer the option of initiating pharmacotherapy rather than waiting until they are ready to quit.
	• If the patient is a member of a special population (e.g., adolescent, pregnant smoker), provide additional information specific to that population.
Assist	Provide aid for the patient to quit. These actions are summarized in the accompanying table.
Arrange	Schedule follow-up contact, either in person or by telephone. Follow-up contact should occur soon after the quit date, preferably during the first week. A second follow-up contact is recommended within the first month. Schedule further follow-up contacts as indicated.
	Congratulate success during each follow-up. If tobacco use has occurred, review circumstances and elicit recommitment to total abstinence. Remind the patient that a lapse can be used as a learning experience. Identify problems already encountered and anticipate challenges in the immediate future. Assess pharmacotherapy use and problems. Consider use or referral to more intensive treatment.

TABLE 11.11 The 5As Approach to Supporting Patients in Smoking Cessation (Tobacco Use and Dependence Guideline Panel, 2008)

Cessation-related interventions may include nicotine replacement therapy, other medications, and support groups/mental health counseling. To maximize the likelihood of success, implementation strategies must be comprehensive (Table 11.12).

Action	Strategies for Implementation
Help the patient with a quit plan	Set a quit date. Ideally, the quit date should be within two weeks.
	Tell family, friends, and coworkers about quitting and request understanding and support.
	Anticipate challenges to planned quit attempt, particularly during the critical first few weeks. These include nicotine withdrawal symptoms.
	Remove tobacco products from the environment. Prior to quitting, avoid smoking in places where they spend a lot of time (e.g., work, home, car).
Provide practical counseling (problem-solving/training)	Abstinence: Total abstinence is essential. “Not even a single puff after the quit date.”
	Past quit experience: Review past quit attempts, including identification of what helped during the quit attempt and what factors contributed to relapse.
	Anticipate triggers or challenges in upcoming attempt: Discuss challenges/triggers and how patient will successfully overcome them.
	Advise patient to remove all tobacco from home, car, and work environment.

TABLE 11.12 Implementation Strategies for Smoking Cessation (Tobacco Use and Dependence Guideline Panel, 2008)

Action	Strategies for Implementation
	Alcohol: Because alcohol can cause relapse, the patient should consider limiting/abstaining from alcohol while quitting.
	Other smokers in the household: Quitting is more difficult when there is another smoker in the household. Patients should encourage housemates to quit with them or not smoke in their presence.
Provide intra-treatment social support	Provide a supportive clinical environment while encouraging the patient in their quit attempt. "My office staff and I are available to assist you."
Help the patient obtain extra-treatment social support	Help the patient develop social support for their quit attempt in their environments outside of treatment. "Ask your spouse/partner, friends, and coworkers to support you in your quit attempt."
Recommend the use of approved pharmacotherapy, except in special circumstances	Recommend the use of pharmacotherapies found to be effective. Explain how these medications increase smoking cessation success and reduce withdrawal symptoms.
Provide supplementary materials	Sources: Federal agencies, nonprofit agencies, or local/state health departments. Offer a free telephone quitline (in the United States, 1-800-QUIT-NOW or 1-800-784-8669 can be used).
	Type: Culturally/racially/educationally/age appropriate for the patient
	Location: Readily available at every clinician's workstation

TABLE 11.12 Implementation Strategies for Smoking Cessation (Tobacco Use and Dependence Guideline Panel, 2008)

Evaluation of Nursing Care for the Patient Who Smokes and/or Vapes

When providing nursing care for the patient who smokes and/or vapes, the nurse uses subjective and objective data to determine next steps. Nursing care may impact physiologic status, medication regimens, and cessation. When evaluating the patient with complications from smoking or vaping, the nurse asks if their respiratory status has stabilized or improved. The nurse can evaluate lung sounds, perceived dyspnea, oxygen requirement, and medication regimen. Regarding smoking and vaping cessation, the nurse can assess any changes in the patient cigarette/e-cigarette usage along with the patient's symptoms and adherence to a medication regimen.

Medical Therapies and Related Care

Medical therapies related to cigarette smoking and vaping focus primarily on treating conditions that have developed and supporting patients to quit. E-cigarettes are not recommended as a cigarette smoking cessation strategy. Nicotine replacement therapy and other medications can help patients stop smoking. For patients with complications related to cigarette smoking, medical treatment will often involve inhalers, bronchodilators, and corticosteroids. Patients may also need to use supplemental oxygen to maintain their respiratory status.

In patients with EVALI, hospital admission may be required, and supplemental oxygen is commonly needed. Antibiotics are commonly utilized; corticosteroids are used in severe cases (Perkins, 2020). When serious complications develop (e.g., diffuse alveolar hemorrhage), emergent treatment is necessary. Bronchoscopy can be used to visualize and stop bleeding. Treatment options for bleeding available via bronchoscopy include topical vasoconstrictors (e.g., epinephrine), tamponade, and lavage with iced saline (Ingbar & Dincer, 2023).

Collaborative care for patients who smoke and vape includes many disciplines. Nursing, medicine, pharmacy, and respiratory therapy will work together on the plan of care that includes medications, oxygen therapy, imaging, and procedures. Social workers and mental health counselors can be important sources of support for patients and

families dealing with smoking-related consequences and challenges with quitting.

Pathophysiology, Risk Factors, and Clinical Manifestations of Environmental Triggers on Respiratory Illness

Work-related asthma is a common respiratory illness related to environmental triggers. Exposure to allergens, high temperatures, humidity extremes, and irritants can cause airway irritation and constriction. Inhaling dust, fumes, gases, and vapors can cause COPD and worsen existing cases. Asbestos exposure can lead to lung irritation as well as cancer. Asbestosis occurs when asbestos is inhaled, and mesothelioma is the asbestos-linked cancer that can arise in the lining of the lungs. Moreover, **black lung disease**, or **pneumoconiosis**, is a pulmonary disease that leads to lung scarring as a result of inhaled coal dusts. Histoplasmosis is a fungal infection caused by inhaling spores from soil (American Lung Association, n.d.).

Due to a variety of respiratory illnesses caused by environmental triggers, the manifestations can vary. Common symptoms do include shortness of breath, productive cough, wheezing, chest pain, and a history of known exposure to an environmental trigger. Patients may be asymptomatic for many years before damage becomes apparent. Diagnosis is made using history and physical, pulmonary function tests, x-ray, tissue biopsy, and CT scan (American Lung Association, n.d.).

Nursing Care of the Patient with Respiratory Illness from Environmental Triggers

Respiratory illness from environmental triggers can be serious, progressive, and debilitating. Nursing care centers on exposure identification, physiologic stabilization, and emotional well-being.

Recognizing Cues and Analyzing Cues

When evaluating patients with a suspected or confirmed respiratory illness related to an environmental trigger, potential exposure to substances and smoking history are both considered. Patients should be questioned about their occupations (e.g., miners, farmers, construction workers, factory workers) to help determine if environmental hazards are present. The nurse considers the possible triggering substance along with the duration and frequency of exposure. It is crucial to understand what, if any, personal protective equipment the patient had access to at the time of potential exposure. Some environmentally triggered respiratory illnesses have a rapid onset; others are delayed for years. Subjective data will include the patient's description of symptoms, including time of onset. The nurse evaluates objective data, including lung sounds, shortness of breath, and cough. Vital signs are evaluated with a focus on respiratory rate and oxygen saturation.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

High-priority findings include acute respiratory distress and hypoxia. The nurse may need to monitor vital signs, prepare a patient for imaging or pulmonary function tests, or administer medications. Many patients with environmentally triggered respiratory illnesses will require supplemental oxygen. Because most of these illnesses are incurable, patient and caregiver stressors are often present, and the nurse prioritizes emotional well-being and coping skills through facilitating access to resources like support groups, financial assistance, and mental health counseling. Smoking cessation education is a high-priority action.

Evaluation of Nursing Care with Respiratory Illness from Environmental Triggers

Because most environmentally triggered respiratory illnesses are permanent, a cure is not usually a possible outcome. For most patients, the goal is to stabilize or improve their respiratory status, at least temporarily. The nurse can evaluate lung sounds, perceived dyspnea, ability to perform activities of daily living, oxygen requirements, and medication regimen to determine the patient's respiratory status.

Medical Therapies and Related Care

Unfortunately, there is no cure for most environmentally triggered lung diseases, although some treatments can delay disease progression. Histoplasmosis is one environmentally triggered lung disease that can be cured; antifungal medication is administered for three months to a year. Key treatment strategies focus on preventing future exposure and smoking cessation. Oxygen therapy will often be necessary with most diseases. Bronchodilators can often improve symptoms by opening up airways. Pulmonary rehabilitation therapy can help some patients improve quality of life and activity tolerance. Surgery, including lung transplantation, may be

necessary in some cases.

LINK TO LEARNING

New medications are becoming available that can slow the progression of some lung diseases. Nintedanib (Ofev) is used to treat idiopathic pulmonary fibrosis as well as lung fibrosis that occurs with scleroderma and progressive fibrosing interstitial lung disease. Review this patient education information from the American College of Rheumatology (https://openstax.org/r/77LungMeds) to learn more.

Summary

11.1 Concepts of Oxygenation and Perfusion

- The respiratory system allows the body to breathe air and oxygenate blood. It is made up of the conducting zone and the respiratory zone.
- The lungs are protected by the ribs and sternum and are covered in protective membranes called pleurae.
- The bronchi branch off into tiny airways called bronchioles, ending in a terminal bronchiole. Terminal bronchioles meet a respiratory bronchiole, then connect to an alveolar duct. Gas exchange occurs in the alveolar sacs, at the end of the alveolar duct.
- Ventilation refers to the movement of air into and out of the lungs. During inhalation, air passes through the conducting zone and travels to the respiratory bronchiole and the alveolar sac. Carbon dioxide in the blood diffuses across the capillaries into the alveoli, leaving the body during exhalation.
- Oxygen molecules from inhaled air pass into the capillaries by diffusion. Most of the oxygen attaches itself to hemoglobin in the red blood cells so it can travel throughout the body, delivering oxygen to tissues.
- Physiologic factors that negatively affect oxygenation include hypoventilation related to decreased respiratory rate, limitations in chest wall/diaphragmatic expansion, and narrowed airways. Additionally, damaged alveoli and pulmonary capillaries, unventilated alveoli, and alveolar filling disorders can also cause inadequate oxygenation.
- Perfusion, as it relates to the respiratory system, means blood is flowing through the pulmonary capillaries. To receive oxygen, blood must be able to flow toward the alveoli, and oxygenated blood must be able to flow into the pulmonary vein so it can travel to the left side of the heart.
- When blood vessels are narrowed or blocked, blood flow decreases, and the lungs are less able to oxygenate blood.

11.2 Upper and Lower Respiratory Assessment

- Subjective assessment obtains information about the patient's history and current symptoms.
- Initial assessment looks at the patient's overall affect and appearance, observing for anxiety, distress, confusion, pallor, cyanosis, sweating, and ability to speak.
- Look at the patient's posture and observe accessory muscle usage, pursed lips, and nasal flaring.
- Before using a stethoscope, note if the patient's breathing is audible.
- Auscultation can identify adventitious lung sounds.
- A normal respiratory rate is twelve to twenty breaths per minute.
- Normal oxygen saturation (SpO_2) is 94 to 100 percent.
- Even with normal vital signs, respiratory problems can be present.
- Both hypoxemia (low blood levels of oxygen) and hypercapnia (high blood levels of carbon dioxide) can cause changes in level of consciousness, irritability, and distress.

11.3 Disorders of the Upper Respiratory System: Bronchiectasis

- Bronchiectasis is a chronic lung disease that leads to widened, damaged airways.
- The supportive structures of the bronchial wall lose elasticity and the bronchi dilates abnormally. The damage and dilation make it harder to clear mucus from the lower airways.
- Bacteria can flourish, causing a recurrent cycle of infection, inflammation, and airway damage.
- Almost all patients with bronchiectasis will have a cough.
- Bronchiectasis is diagnosed by CT scan.
- Crackles are the most common adventitious lung sound.
- Patients with bronchiectasis need to avoid environmental irritants, including smoking, secondhand smoke, and air pollution.
- Antibiotic therapy is often needed to treat an infection.
- Airway clearance therapies are necessary to help patients raise and clear phlegm.

11.4 Disorders of the Lower Respiratory System: Asthma

- Asthma is one of the most prevalent diseases in the United States.
- There are significant sex-, race-, and socioeconomic-based disparities in asthma care and outcomes.

- An asthma attack (or exacerbation) occurs when a trigger causes inflammation; this narrows the airway, causing bronchoconstriction.
- In a patient with asthma, the airways are considered hyperresponsive, meaning they narrow more than usual in response to stimuli.
- Asthma is classified into four stages (intermittent, mild, moderate, severe) based on how often symptoms occur.
- Shortness of breath, cough that is often worse at night, wheezing, and chest tightness are classic asthma symptoms.
- Pulmonary function testing confirms an asthma diagnosis.
- Bronchodilators are used to treat asthma; they work by opening narrowed airways.
- Environmental irritants can trigger asthma exacerbations.
- Patient education includes using an inhaler and peak flow meter, implementing an asthma action plan, and strategies to avoid triggers.
- Medication management may include both short- and long-acting medications.

11.5 Disorders of the Lower Respiratory System: Chronic Obstructive Pulmonary Disease

- COPD is a common chronic disease in the United States.
- Smoking is the primary risk factor for COPD.
- In patients with COPD, inflammation causes airway changes, including narrowing, smooth muscle hypertrophy, and increased mucous production.
- Problems with exhalation develop due to emphysema; alveolar walls become damaged and lose elasticity.
- Patient-reported symptoms include cough, progressive shortness of breath, and mucous production.
- Spirometry testing is used to diagnose COPD.
- Spirometry testing is also used to stage COPD; the disease can be mild, moderate, severe, or very severe.
- Medication management includes both short- and long-acting medications.
- Many patients with COPD will need to use long-term oxygen therapy.
- Vaccinations for preventable respiratory diseases are an important part of COPD management.
- Signs of an acute exacerbation include worsening cough, increased wheezing, fever with no other cause, recent upper respiratory infection, increased respiratory rate, or increased heart rate.

11.6 Disorders of the Lower Respiratory System: Pneumothorax

- COPD and smoking increase the risk of pneumothorax.
- Pneumothorax occurs when air accumulates in the pleural space, causing the lung to collapse and deflate, limiting the area available for oxygenation and ventilation.
- Patient-reported symptoms commonly include a rapid onset of dyspnea, cough, and intense chest pain that is worse with movement.
- Vital sign changes can include an increased respiratory rate, decreased oxygen saturation, and increased heart rate.
- Physical assessment findings can include unequal chest expansion and decreased or absent breath sounds.
- Pneumothorax is diagnosed with imaging, most commonly chest x-ray.
- A small pneumothorax may be asymptomatic and not require treatment.
- More substantial pneumothoraxes will require chest tube placement with connection to a specialized drainage device.
- Surgery is used to treat pneumothorax in certain patient populations.
- If there is an open chest wound from a penetrating trauma, the nurse must be prepared to apply a three-sided occlusive dressing.
- A tension pneumothorax occurs when a large volume of air enters the pleural space, causing a major amount of lung collapse and forcing the heart and trachea to shift.
- Tension pneumothorax is treated with immediate needle decompression.
- Treatment of pneumothorax is often painful; pain assessment and management are necessary.
- Patient education includes information about the treatment plan, mobility restrictions related to procedures or inserted tubes, and pain management.

11.7 Disorders of the Lower Respiratory System: Pneumonia and Aspiration

- Pneumonia occurs when infection occurs in the lungs and tissues become inflamed.
- Pneumonia can be caused by bacteria, a virus, or a fungus.
- Community-acquired pneumonia is common; hospital-acquired and ventilator-acquired pneumonia can also occur.
- Typical symptoms include cough, fever, and fatigue.
- Patients with COPD have the highest risk of hospitalization for pneumonia.
- Other high-risk diagnoses include heart disease, diabetes, smoking, alcohol and opioid use, and immunosuppression.
- Imaging, usually chest x-ray, is used for conclusive diagnosis.
- Sputum cultures and viral testing can identify the responsible organism.
- Treatment may involve antibiotics, antivirals, or antifungal medications.
- Ongoing assessment of a patient's respiratory effort, observing for signs of labored breathing, is a key nursing task.
- In serious cases, supplemental oxygen, including noninvasive ventilation or a ventilator, may be necessary.
- Patient education topics may include medication management, oxygen therapy, vaccines, and ventilatory support.
- In cases of aspiration pneumonia, patient education will often center around safe swallowing techniques.

11.8 Disorders of the Lower Respiratory System: Tuberculosis

- While TB is relatively rare in the United States, the global burden of disease is immense.
- TB is a highly contagious airborne illness.
- Immunocompromise increases the risk of infection and serious disease.
- Common symptoms include fever, cough, night sweats, weight loss, fatigue, chills, decreased appetite, shortness of breath, and pleuritic chest pain.
- Diagnostic evaluation of a patient with suspected TB may include a blood or skin test and imaging. A conclusive diagnosis can only be made, however, by examining a sputum sample for the presence of tubercle bacilli.
- Because TB is an airborne illness, infection prevention is a high priority.
- Patients should ideally be placed in a private, negative airflow room. Staff PPE should include a respirator that has been fit tested for everyone.
- TB generally requires a six-month treatment course of antibiotics. Incomplete treatment can result in ongoing infection and antibiotic resistance.

11.9 Disorders of the Lower Respiratory System: Cystic Fibrosis

- CF is an inherited genetic disorder that affects about one in 3,500 births in the United States.
- Most patients are diagnosed in infancy; virtually all are diagnosed prior to age two.
- The gene mutation impairs the movement of sodium and chloride ions across cell membranes, causing thick mucus to build up in the lungs and throughout the body.
- CF is conclusively diagnosed using a sweat test; it will show elevated levels of sodium and chloride.
- Because of treatment advances, the average life expectancy of a person with CF has increased to the age of forty.
- Antibiotics are commonly used to treat exacerbations; some patients will require prophylactic antibiotics.
- Inhaled medications and airway clearance techniques are used to help patients raise thick mucus.
- Many patients with CF will have pancreatic insufficiency, so supplementation with pancreatic enzymes is necessary.

11.10 Effects of Smoking, Vaping, and Environmental Triggers of the Respiratory System

- Cigarette smoking is a major cause of preventable morbidity and mortality worldwide.
- Vaping, or e-cigarette usage, involves heating a liquid to a high temperature; particles become a fine vapor, which is inhaled. Many of the inhaled components are damaging to lung tissue.
- There are many environmental and occupational triggers for respiratory disease.

- Most environmentally triggered respiratory diseases are not curable.
- Personal protective equipment can mitigate the risk of occupationally triggered respiratory diseases if available and used properly.
- Coaching and patient education around smoking cessation is a complex, challenging, high-priority intervention.

Key Terms

acute respiratory distress syndrome (ARDS) potentially fatal lung injury that can be triggered by a variety of events; fluid builds up in the lungs, oxygen levels drop, and scarring can occur
adventitious lung sounds breath sounds other than a clear sound of air
alveolar sac group of alveoli
alveolus individual, grapelike sac in the lungs where gas exchange occurs
angioedema soft tissue swelling in the deep layers of the skin, most commonly in the mouth, eyelids, and genitals
aspiration food, fluid, upper airway secretions, or emesis enter the trachea and respiratory tract
asthma attack (also: *asthma exacerbation*) inflammation narrows the airway, making it harder for the lungs to expand
atelectasis condition that causes a partial or complete collapse of the lung
BiPAP bilevel positive airway pressure, a form of noninvasive ventilation that uses a tight-fitting mask over the nose and/or mouth to increase oxygen levels and lower carbon dioxide levels; bilevel means there are two pressure settings: inhalation positive airway pressure (IPAP) and exhalation positive airway pressure (EPAP)
black lung disease pulmonary disease that leads to lung scarring due to inhaled coal dusts, also known as pneumoconiosis
bradypnea less than twelve breaths per minute
bronchial breath sounds heard over the trachea and larynx and are high-pitched and loud
bronchiectasis condition in which the elastic, supportive structures of the bronchial wall become damaged, and the bronchi abnormally dilate
bronchoconstriction smooth muscles in the airways contract, causing the airway to narrow
bronchodilator medication that opens narrowed airways
bronchoscope thin tube inserted into the mouth or nose with a camera for visual examination of lung tissue, can obtain biopsy samples and treat blockages
bronchovesicular breath sounds medium-pitched and heard over the major bronchi
cachexia disorder that causes loss of muscle and adipose tissue
capnography (also: *end-tidal carbon dioxide [$EtCO_2$] monitoring*) noninvasive way to measure exhaled carbon dioxide and provide information about ventilation
carina point where the trachea splits into the right and left primary bronchi
chest physical therapy airway clearance technique that can improve drainage and mobilization of mucus
chest tube (also: **thoracostomy tube**) tube inserted through the skin, into the pleural space, to drain air, fluid, or blood
chronic obstructive pulmonary disease (COPD) widely prevalent obstructive respiratory disease
clubbing bulbous enlargement of the tips of the fingers due to chronic hypoxia
conducting zone all parts of the respiratory system that do not participate in gas exchange, the passageways for air to flow into and out of the lungs
crepitus feels like a popping or crackling sensation when the skin is palpated; is a sign of air trapped under the subcutaneous tissues
diffusion movement of substances from an area of high concentration to an area of low concentration
droplet nuclei tiny particles expelled from an infected person during talking, coughing, or singing; they remain airborne for several hours
emphysema occurs when alveolar walls become damaged and lose elasticity, resulting in problems with exhalation
fine crackles (also: **rales**) popping or crackling sounds heard on inspiration as collapsed airways reopen
forced expiratory volume (FEV_1) maximum exhaled volume of air in one second
forced vital capacity (FVC) overall maximum volume of air that can be exhaled
granuloma walled-off capsule that develops as the body attempts to contain tubercle bacilli

hemoptysis coughing up blood
hospital-acquired pneumonia (HAP) pneumonia that develops in a hospital setting
hypercapnia high blood levels of carbon dioxide
hypoxemia low blood levels of oxygen
iatrogenic pneumothorax air enters the pleural space due to a complication from surgery or invasive procedure (e.g., placement of a central venous catheter)
idiopathic having an unknown cause
immune globulin product that may be administered intravenously or subcutaneously to provide necessary antibodies to strengthen the immune system
laryngopharynx most inferior portion of the pharynx, allows passage of both air and food
larynx cartilaginous structure that joins the pharynx to the trachea and regulates how much air goes in and out of the lungs, allows vibrations in the vocal cords to produce sound
meconium newborn's first stool
medulla oblongata respiratory center of the brain, controls breathing by responding to shifts in carbon dioxide, oxygen, and blood pH
nasopharynx region of the pharynx allows air to pass from the nasal cavity toward the trachea
needle decompression treatment for tension pneumothorax where a large needle is inserted through the skin, between the ribs, into the pleural space; the large volume of air in the pleural space escapes through the needle and the lung can reexpand
oropharynx region of the pharynx, allows passage of both air and food
oxygenation process that occurs when oxygen from the air makes its way into the bloodstream
oxyhemoglobin bright red molecule formed when oxygen binds to hemoglobin
pancreatic enzymes supplementary medication required by patients with CF due to pancreatic insufficiency
partial pressure how much of a gas is dissolved in the blood
peak flow meter device that measures lung function and allows patients to track and observe trends
perfusion blood flow
pharynx muscular tube with an inner mucous membrane lining, it connects the nasal passages and oral cavity to the trachea and esophagus
pleurae protective membranes that encase the lungs
pleural effusion accumulation of fluid in the pleural space
pleuritic severe, sudden type of chest pain that occurs with inhalation and exhalation; described as burning, stabbing, or sharp
pleurodesis technique used to heal the break in the pleural space by creating an inflammatory reaction in the pleural space
pneumoconiosis pulmonary disease that leads to lung scarring due to inhaled coal dusts, also known as black lung disease
positive expiratory pressure device airway clearance device that lets the patient breathe in easily but creates resistance as they exhale, slowing down the breath and causing the patient to increase the force of exhalation; air is more able to move behind the mucus and helps to dislodge it
primary spontaneous pneumothorax air enters the pleural space spontaneously; there is no underlying lung disease
pulse oximeter noninvasive device that provides information about blood oxygen saturation
rales (also: **fine crackles**) popping or crackling sounds heard on inspiration as collapsed airways reopen
respiratory zone parts of the respiratory system that perform gas exchange
ronchi coarse, loud sounds that occur due to constriction in the larger airways due to mucus or fluid
rub grating sound
secondary spontaneous pneumothorax air enters the pleural space spontaneously as a complication of underlying lung disease
spirometry pulmonary function test that measures the maximum volume of air that can be inhaled and how much someone can forcefully exhale in one second
stridor harsh, high-pitched sound heard only on inspiration that is often loud enough to hear without a stethoscope
subcutaneous emphysema occurs when high-pressure air is forced through the tissues, creates a "popping"

sensation with palpation and can cause visible swelling

sweat test conclusive diagnostic test for CF; a chemical and a small amount of electrical stimulation are applied to the skin to encourage sweat production. Sweat is collected and analyzed; elevated levels of sodium and chloride confirm a diagnosis of CF

tachypnea more than twenty breaths per minute

tension pneumothorax when a large volume of air enters the pleural space, in addition to causing a major amount of lung collapse, the high pressure also forces the heart and trachea to shift

thoracostomy tube (also: **chest tube**) tube inserted through the skin, into the pleural space, to drain air, fluid, or blood

trachea anterior to the esophagus, this tube extends downward from the larynx to the lungs

tracheal deviation trachea in a non-midline position

traumatic pneumothorax air enters the pleural space due to traumatic injury

tripod position upright position with hands braced on knees or a table. This position maximizes the space available for the lungs to expand and is often seen in respiratory distress

vaping using an e-cigarette that heats a solution so it vaporizes and can be inhaled, the solution can contain nicotine, THC, butane hash oils, cannabidiol, and other additives

ventilation movement of air into and out of the lungs

ventilator-associated pneumonia (VAP) pneumonia that occurs after a ventilator is initiated

vesicular breath sounds heard over the lung surfaces, are lower-pitched, and often described as soft, rustling sounds

wheezes whistling-type noises produced during expiration (and sometimes inspiration)

Assessments

Review Questions

1. What is the primary way oxygen enters the blood and travels?

a. Oxygen enters capillaries by diffusion, then attaches to hemoglobin.
b. Oxygen enters capillaries by perfusion, then attaches to hemoglobin.
c. Oxygen enters capillaries by diffusion, then attaches to platelets.
d. Oxygen enters capillaries by perfusion, then attaches to platelets.

2. What condition could impact both oxygenation and ventilation?

a. congestive heart failure
b. hypertension
c. lung cancer
d. asthma

3. You are providing care to a patient with postoperative atelectasis. The patient states, “The doctor told me parts of my lungs aren’t working. I don’t understand, I had surgery on my colon.” What is an example of a response by the nurse accurately summarizes atelectasis?

a. “The anesthesia caused problems for your lungs that should wear off in 12 to 24 hours.”
b. “Due to swelling from the surgery, your airways have narrowed.”
c. “When you’re not able to breathe as deeply as usual, maybe because of discomfort, small parts of the lung become collapsed.”
d. “Most likely there is a minor hemorrhage in your lungs related to the surgery; it usually resolves on its own.”

4. When assessing the components of an upper respiratory airway assessment, what should the nurse do after auscultating with a stethoscope?

a. Palpate the patient’s chest.
b. Position the patient.
c. Note if the patient has any audible sounds with breathing.
d. Note for any accessory muscle use with inspiration or expiration.

5. What term is used for a harsh, high-pitched sound, heard on inspiration, often loud enough to hear without a stethoscope?
   a. stridor
   b. wheezes
   c. rales
   d. crepitus

6. What assessment finding would the nurse utilize to discuss bulbous enlargement of the fingertips?
   a. clubbing
   b. tripod
   c. hypoxemia
   d. stridor

7. How can bronchiectasis be best summarized?
   a. a chronic condition that results in widened, damaged airways
   b. a chronic condition that is caused by fluid accumulation in the lining of the lung
   c. a chronic condition that results from medication toxicity
   d. a chronic condition that is caused by blood clots in the lung

8. What diagnostic would best support a diagnosis of bronchiectasis?
   a. patient reporting a constant cough
   b. chest x-ray with evidence of atelectasis
   c. elevated eosinophils
   d. patient reporting green frothy sputum

9. You are providing care for a patient with bronchiectasis. They report that they just coughed up sputum that was "mostly blood." What is the priority nursing intervention?
   a. Ensure that suction is available and ready to use.
   b. Notify the treating clinician.
   c. Apply supplemental oxygen via nasal cannula.
   d. Obtain sputum sample and send to the laboratory.

10. When providing patient education to a patient with bronchiectasis, what teaching points does the nurse include? Select all that apply.
   a. Immunization against preventable respiratory illnesses can help prevent complications.
   b. Exposure to air pollution can worsen disease.
   c. Avoiding secondhand smoke is helpful for patients with bronchiectasis.
   d. All patients with bronchiectasis should avoid smoking.

11. What is a known trigger of asthma exacerbations?
   a. hormonal fluctuations
   b. warm air
   c. steroids
   d. immobility

12. What diagnostic would the nurse anticipate if a patient is suspected to have asthma?
   a. pulmonary function test
   b. arterial blood gas
   c. capnography
   d. bronchodilation

13. You are working in a primary care office and receive a phone call from a patient with asthma. They state that their symptoms have been worse, and they've needed to use rescue medications frequently. They say, "My

asthma action plan says to go to the hospital, but I feel like I can manage this at home." How should the nurse respond?

a. "As long as your rescue medications are providing relief, it's okay to monitor things at home for the next two to four hours."
b. "You need to go to the hospital immediately. Your symptoms could get even more severe, very quickly."
c. "I'll discuss this with the physician and call you back later today."
d. "Doubling the dose of your rescue medications should stabilize your symptoms."

14. You are providing care to a patient with asthma. They state, "When I get really short of breath, I use the steroid inhaler, but it doesn't seem to be helping." How should the nurse respond?

a. "Let's review the instructions for each of your inhalers. The steroid inhalers are long-acting so aren't typically meant to be used when symptoms are flaring."
b. "It sounds like the dose might need to be increased."
c. "Are you rinsing your mouth with water after use? That's important to do with steroid inhalers."
d. "Let's talk to the doctor; I think another round of lung function testing might help us get some answers."

15. Your patient is being evaluated for a potential new diagnosis of asthma. They state, "I don't think I need any tests, I'm sure I have it. A lot of people in my family have asthma, and I tried one of their inhalers and it made me feel better." How should the nurse respond?

a. "A family history and a response to medication like that confirms the diagnosis."
b. "Those symptoms certainly suggest asthma; to conclusively diagnose it, we'll need to do a CT scan of your chest."
c. "Those symptoms sound like asthma. To be sure, we'll need to do some tests called spirometry."
d. "We'll do a blood test to be confirm that it's definitely asthma."

16. What risk is associated with steroid inhaler use?

a. oral *Candida* infection
b. wheezing
c. tachycardia
d. barrel-shaped chest

17. Which of the following values would represent a diagnostic finding of COPD?

a. FEV_1 0.5 (FEV_1 levels < 0.7 represent a diagnosis of COPD)
b. FEV_1 0.8
c. pulse oximeter reading 91 percent
d. carbon dioxide level 46 mm HG

18. While providing care for a patient hospitalized with a COPD exacerbation requiring supplemental oxygen therapy, what is a priority intervention?

a. Titrate supplemental oxygen up to an oxygen saturation level of 100 percent.
b. Use no more than 1–2 L of supplemental oxygen.
c. Assess for signs of CO_2 retention thirty to sixty minutes after starting oxygen.
d. Assess for signs of peripheral vasoconstriction related to supplemental oxygen.

19. Identify the abnormal lung sounds associated with pneumothorax:

a. diminished or absent
b. stridor
c. wheezing
d. crackles

20. What dressing would be appropriate to place over a chest tube that has become dislodged?

a. sterile gauze
b. band aid

c. Vaseline gauze
d. paper towel

21. When providing care for a patient with a pneumothorax being treated with a chest tube, what action does the nurse take if the tube becomes dislodged?
a. Apply sterile gauze at the insertion site.
b. Start CPR immediately.
c. Apply 100 percent oxygen via face mask.
d. Apply a three-sided occlusive dressing.

22. You are caring for a sixty-two-year-old patient with COPD, admitted for a large left-sided pneumothorax. A chest tube has been in place for two days connected to a drainage system. What physical assessment finding suggests resolution of the pneumothorax?
a. lung sounds audible in all lung fields
b. trachea is midline
c. ongoing air leakage in chest drainage system
d. oxygen requirement has resolved

23. What is the primary risk factor to develop pneumonia during a hospitalization?
a. COPD
b. age > 65
c. smoking
d. diabetes

24. What indicator would the nurse expect to find when the patient is having a therapeutic response to antibiotics for pneumonia?
a. white count 12,500/microliter
b. pulse oximetry 90 percent
c. patient reporting improved dyspnea
d. a smaller consolidation on chest x-ray

25. Your patient states, "The doctor told me they think I have pneumonia, and I'll need some tests. How will we know for sure if I have pneumonia?" What is an example of an accurate response from the nurse?
a. "To conclusively diagnose pneumonia, an invasive test called bronchoscopy is necessary."
b. "A sample of mucus, or sputum, needs to be tested to identify the organism causing pneumonia."
c. "A chest x-ray is usually how we diagnose pneumonia."
d. "Blood tests provide conclusive evidence of pneumonia."

26. A patient is being treated in an inpatient unit for suspected community-acquired bacterial pneumonia. A COVID test was negative. They have a strong, frequent cough, productive of sputum. What PPE is indicated during direct patient care?
a. gloves
b. fit tested respirator and face shield
c. surgical mask and eye protection
d. fit tested respirator

27. Identify a symptom commonly present in active TB infection.
a. night sweats
b. weight gain
c. stridor
d. frothy sputum

28. What diagnostic procedure would be able to determine if TB is in its active form?

a. PPD skin test
b. chest x-ray
c. QuantiFERON blood test
d. sputum sample

29. What is the priority action in the care of a patient with active TB?
a. administration of antibiotics
b. prevention of the spread of infection
c. collecting a sputum specimen
d. having the patient wear a mask

30. Your patient is being evaluated for suspected TB. They ask, "How will you know if I have TB or if it's something else?" What is an example of an accurate response from the nurse?
a. "A chest x-ray will provide the information that we need."
b. "A CT scan of your chest is used because it will provide more detailed images than an x-ray."
c. "A blood test provides conclusive information about if you have TB or not."
d. "We'll take a sample of sputum—the mucus that you cough up—and send it to the lab."

31. Your patient is being treated for active TB and has been receiving antibiotic therapy for the past month. They state, "Lately I've been forgetting to take the medication. But I'm feeling a lot better and not even coughing anymore. I figured I was done with it, so I stopped the medication." What is an example of an appropriate response from the nurse?
a. "Taking the medication is not optional. If you can't take it as prescribed, we'll be forced to admit you to the hospital for supervised treatment."
b. "You completed a month of treatment, that is usually adequate."
c. "Even though you are feeling better, you'll need to finish another month of treatment."
d. "Let's talk about ways to help you remember to take the medication. There are some electronic options that can be helpful."

32. Identify the diagnostic test used to conclusively diagnose CF.
a. sweat test
b. chest x-ray
c. chest CT
d. pulmonary function tests

33. The patient has been prescribed an airway clearance vest. The parent asks, "Tell me again how this works." Which statement by the nurse best summarizes how an airway clearance vest works?
a. "A compressor sends air into and out of the vest. It causes vibrations and pressure that can help to break up mucus."
b. "The vest is worn at night and provides positive pressure to help keep the airway open."
c. "A snug-fitting vest provides postural support and helps them to be able to take deeper breaths."
d. "The vest sends air into and out of the mouth and nose. It causes vibrations and pressure that can help to break up mucus."

34. You are providing care for a patient with cystic fibrosis admitted to the hospital for pneumonia. What action by the nurse takes priority?
a. administering antibiotics
b. obtaining a sputum sample for culture
c. administering pancreatic enzymes
d. assessing respiratory rate and oxygen saturation

35. What outcome suggests that the patient's condition has improved?
a. Lung sounds demonstrate bilateral crackles throughout lung fields.

b. Patient is coughing approximately once an hour.
c. The patient's temperature is 38.8°C/102°F.
d. The patient's respiratory rate is 24.

36. Identify an environmentally triggered respiratory illness that can be cured.
a. histoplasmosis
b. asbestosis
c. mesothelioma
d. black lung disease (pneumoconiosis)

37. You are providing care for a patient with COPD who continues to smoke. When other clinicians had previously attempted to provide smoking cessation education, the patient had become defensive and dismissive. What is an example of an appropriate response from the nurse?
a. "I need you to know that quitting smoking is the most significant thing you can do for your health today and in the future. We'll support you every step of the way."
b. "We recommend that you cut back during times of illness."
c. "I know you weren't ready to talk about your smoking at the last visit; let's consider talking about it at your next visit."
d. "If you are unable to quit smoking, unfortunately you'll need to find another physician. We only provide care to nonsmokers."

38. Your patient has a new diagnosis of COPD. They have a twenty pack-year smoking history. They state, "I don't think smoking had anything to do with it. I think this COPD must have been caused by all that time I spent working on engines, getting exposed to fumes and chemicals." What is an example of an appropriate response from the nurse?
a. "Smoking is the biggest risk factor for COPD, though workplace exposures and fumes do sometimes play a part."
b. "Smoking typically only causes COPD when there is a fifty pack-year history. Your workplace exposures are probably the primary cause."
c. "It's most likely that you inherited a genetic disposition to COPD."
d. "Because you live in an area with unhealthy air quality, the COPD was most likely caused by dust and fumes in the air."

Check Your Understanding Questions

1. Describe some of the ways the respiratory system protects itself from foreign bodies and pathogens.

2. Describe some assessment findings, other than vital sign changes and lung sound abnormalities, that can indicate respiratory system problems.

3. Describe how bronchiectasis increases infection risk.

4. Describe how a nurse would evaluate the efficacy of nursing care delivered to a patient with bronchiectasis.

5. Describe bronchoconstriction and how bronchodilators improve asthma symptoms.

6. Describe some interventions a patient would need to take in an asthma action plan.

7. Describe strategies to prevent COPD exacerbations.

8. Describe how chest tube placement treats pneumothorax.

9. Describe the potential physical assessment findings for a patient with severe pneumonia.

10. Describe airborne infection isolation precautions and why this is necessary for TB patients.

11. Describe how the genetic mutation causes respiratory problems in CF.

12. Describe how vaping causes lung damage.

Reflection Questions

1. What information might you need to identify a perfusion disorder affecting the respiratory system?
2. You are providing care to a patient with pneumonia in an inpatient setting. Which upper respiratory assessment would the nurse expect to find?
3. Which cues would the nurse recognize as symptoms of elevated carbon dioxide levels?
4. A nurse has conducted an educational intervention for a patient who is newly diagnosed with asthma. Briefly discuss how the nurse would evaluate the efficacy of the teaching.
5. Discuss how trauma patients are at risk for pneumothorax.
6. What clinical assessment findings would the nurse expect for a patient to be hospitalized in the intensive care unit for pneumonia?

Critical-Thinking Questions about Case Studies

1. Refer to COVID Complications: Part 1.
   Designate which cues in Option 1 are recognized with the rationales in Option 2.
   a. Option 1: respiratory failure; Option 2: bacterial pneumonia
   b. Option 1: increased work of heart; Option 2: hypertension and tachycardia
   c. Option 1: fever, fatigue, cough; Option 2: Covid

2. Refer to COVID Complications: Part 1.
   The nurse is planning next actions for this patient. List the cues that are relevant for this patient.

Competency-Based Assessments

1. A patient who has been a smoker for twenty-eight years is admitted to the medical unit for shortness of breath. The nurse observes the patient in the bed is very short of breath and showing signs of respiratory distress despite being on five liters nasal canula. Develop a plan of care that outlines what steps the nurse should take for each following intervention.
   1. Obtain a pulse oximetry reading.
   2. Position the head of the bed to high Fowler's position.
   3. Measure the patient's blood pressure.
   4. Call the lab for (ABG) arterial blood gas results.

2. Conduct a brief internet search on the risk factors and populations at risk for bronchiectasis. Develop a five-minute presentation identifying what age groups and comorbid conditions elevate the risk.
3. Develop a presentation to present at a community health fair that discusses how lifestyle practices of smoking lead to COPD.
4. Create a teaching plan for a patient who is starting rifampin for treatment of TB.
5. Conduct an internet search in how high-risk patient populations are screened antenatally for CF. Develop a poster presentation describing what resources are there in your community.

CHAPTER 12
Cardiovascular System

FIGURE 12.1 Monitoring patients who are challenged by cardiovascular disease is an important part of cardiac rehabilitation. While this chapter focuses on common inpatient cardiac diseases, optimization of perfusion also occurs in the outpatient sector. (credit: "Running and Motivation" by Airman First Class Jelani Gibson/Sheppard Air Force Base, Public Domain)

CHAPTER OUTLINE

INTRODUCTION Cardiovascular care is inclusive of all populations nurses work with. The concepts of oxygenation and perfusion work synergistically to ensure optimal oxygenated blood flow is delivered to all essential tissues. While the physiological functions of cellular compliance are dependent on these actions, patient response also changes when there are alterations in oxygenation and perfusion. This chapter explores common cardiovascular diseases nurses encounter in the medical-surgical setting. Each of the modules introduce overlapping themes of primary, secondary, and tertiary preventive strategies, along with the identification of modifiable and nonmodifiable risk factors. But first, it is important to do a brief overview of cardiovascular physiology.

12.1 Cardiovascular Overview

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss anatomy of the coronaries, valves, arteries, veins, and cardiac muscle
- Review cardiac physiology
- Define cardiac output, stroke volume, preload, and afterload

The cardiovascular system performs the essential role of ensuring that oxygenated blood and essential nutrients are efficiently delivered throughout the body. Understanding the precise anatomy and physiology of the heart and its associated structures, including the heart valves, major arteries and veins, and the cardiac muscle itself, is crucial for grasping their roles in maintaining cardiovascular health. We explore how the heart's chambers and valves orchestrate the flow of blood, and examine the functional dynamics of cardiac output, stroke volume, preload, and afterload. By integrating this knowledge, you will gain a comprehensive understanding of the heart's mechanical and physiological processes, which are fundamental to assessing and managing cardiovascular health in clinical practice.

Cardiac Anatomy

The human heart, which is roughly the size of a human fist, resides slightly left to the sternal border (Figure 12.2). The external tissue comprises a thin serous sack, known as the pericardium, that contains roughly 15-50 milliliters of serous fluid (Fender & Zack, 2021). Pericardial fluid permits the contractile action of the heart without adhering to the chest wall.

There are two major venous systems bringing blood to the heart from the systemic circulation, the superior and inferior vena cava, from the right atrium, through the tricuspid valve and into the right ventricle to be sent to the pulmonary unit. The pulmonary vein returns oxygenated blood to the left atrium. The small coronary arteries, which are discussed in 12.5 Myocardial Infarction, bring oxygenated blood to the cardiac muscle for a multitude of reasons. The pulmonary artery delivers deoxygenated blood from the right ventricle to the pulmonary circuit for oxygenation and, once oxygenated, returns the blood to the right atria, through the mitral valve and to the right ventricle to be expelled through the aorta to systemic circulation. Within the four cardiac chambers (left atrium, left ventricle, right atrium, and right ventricle), there is the endocardium that has fibrous structures securing valvular functions inside the heart. The myocardium, which is the middle and thickest part of the cardiac muscle, is encapsulated by the epicardium. This layer is encapsulated by the pericardial sac.

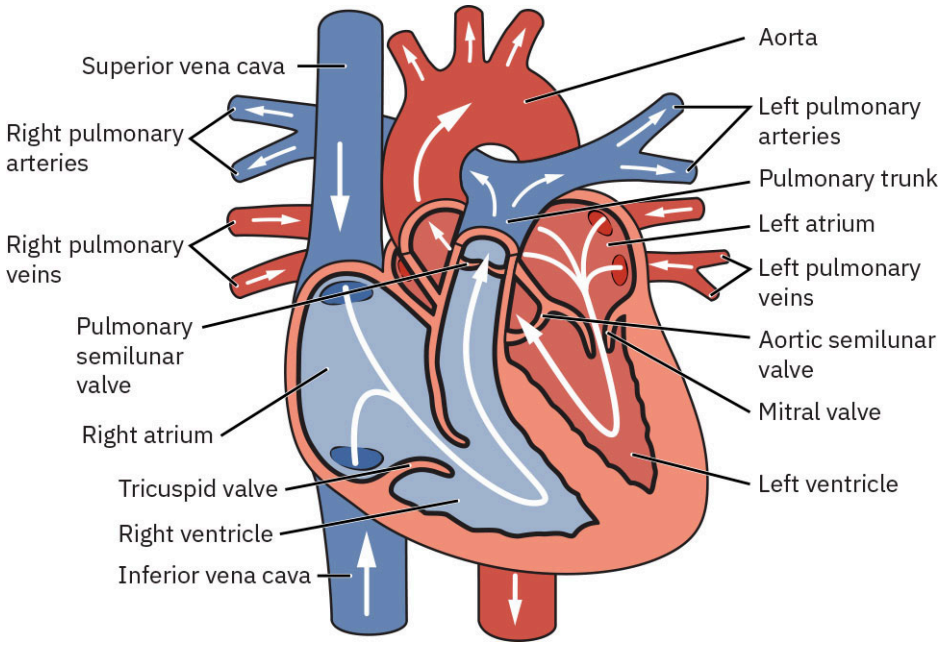

FIGURE 12.2 Blood flows through the heart, following the direction of the arrows. Blue represents deoxygenated blood, and red represents oxygenated blood. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Valves act essentially as “gates” that open and close during different parts of the cardiac cycle. The mitral and tricuspid valves communicate between the atria and ventricles and open during ventricular filling and close during ventricular contraction. In contrast, the aortic and pulmonic valves close during ventricular filling and open during ventricular contraction. The purpose of these structures is to keep a forward flow of blood going to the pulmonary unit for oxygenation and forward flow to the systemic circulation.

Myocardial Cell Physiology

Myocardial cells, also referred to as myocytes, are unique in that they can contract, stretch, and remodel. Also, they can be excited by neurological impulses. An electrical impulse is generated by the native “pacemaker” or sinoatrial node. Deep within the cardiac myocyte is a sodium-potassium ion pump, in which there is an ion exchange that generates an electrical impulse, defined as an action potential (Figure 12.3). However, other influences from the adrenal glands, the brain, and changes in volume status can also influence the nerve impulse. These impulses, ignited by an action potential, occur under the influences of sodium ions going in and potassium ions going out. With these chemical exchanges, an impulse is generated through the membrane and creates a muscular contraction.

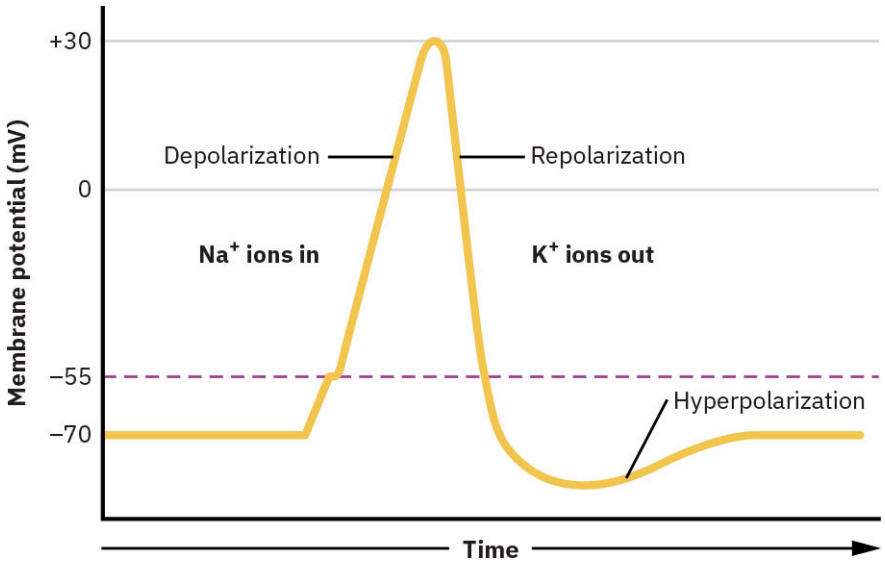

FIGURE 12.3 Here, a stimulus is occurring, creating depolarization, in which there is an influx of sodium ions, and during repolarization, there is flux of potassium ions, creating a muscular contraction. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Cardiac Physiology Terminology

Each minute, the heart perfuses a total of 2 to 4 liters of blood out through the aorta, known as **cardiac output**. Cardiac output varies depending on disease state, gender, age, and other factors. The **stroke volume** is the amount of blood pumped out of the left ventricle during systolic contraction. The initial stretch of the cardiac cells prior to contraction is called **preload**, while **afterload** is the amount of pressure the heart needs to exert during ventricular contraction. Medications and certain diseases, such as coronary artery disease and heart failure, can affect these functions. Nurses must have a fundamental understanding of these terms as these measurements will be greatly affected during a cardiac ailment and with pharmacological actions.

12.2 Dysrhythmia

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the anatomical and physiological functions of the cardiac electrical system
- Discuss and compare pathophysiology, clinical manifestations, and nursing care of bradycardic and tachycardic dysrhythmias
- Discuss and compare pathophysiology, clinical manifestations, and nursing care of ectopic beats
- Discuss and compare pathophysiology, clinical manifestations, and nursing care of heart blocks
- Discuss and compare pathophysiology, clinical manifestations, and nursing care of atrial fibrillation and atrial flutter
- Discuss and compare pathophysiology, clinical manifestations, and nursing care of ventricular tachycardia and ventricular fibrillation
- Discuss and compare pathophysiology, clinical manifestations, and nursing care of asystole
- Evaluate the nursing care of the patient with dysrhythmia

Cardiac myocytes require coronary perfusion for contractility. Concepts for disturbances in cardiac rhythms centralize around the ability of cardiac myocytes to conduct electricity, which assist the atrial and ventricular contraction. If there is a defect in the cardiac electrical conduction system, it leads to contractility problems. Figure 12.4 summarizes the conduction system of the heart.

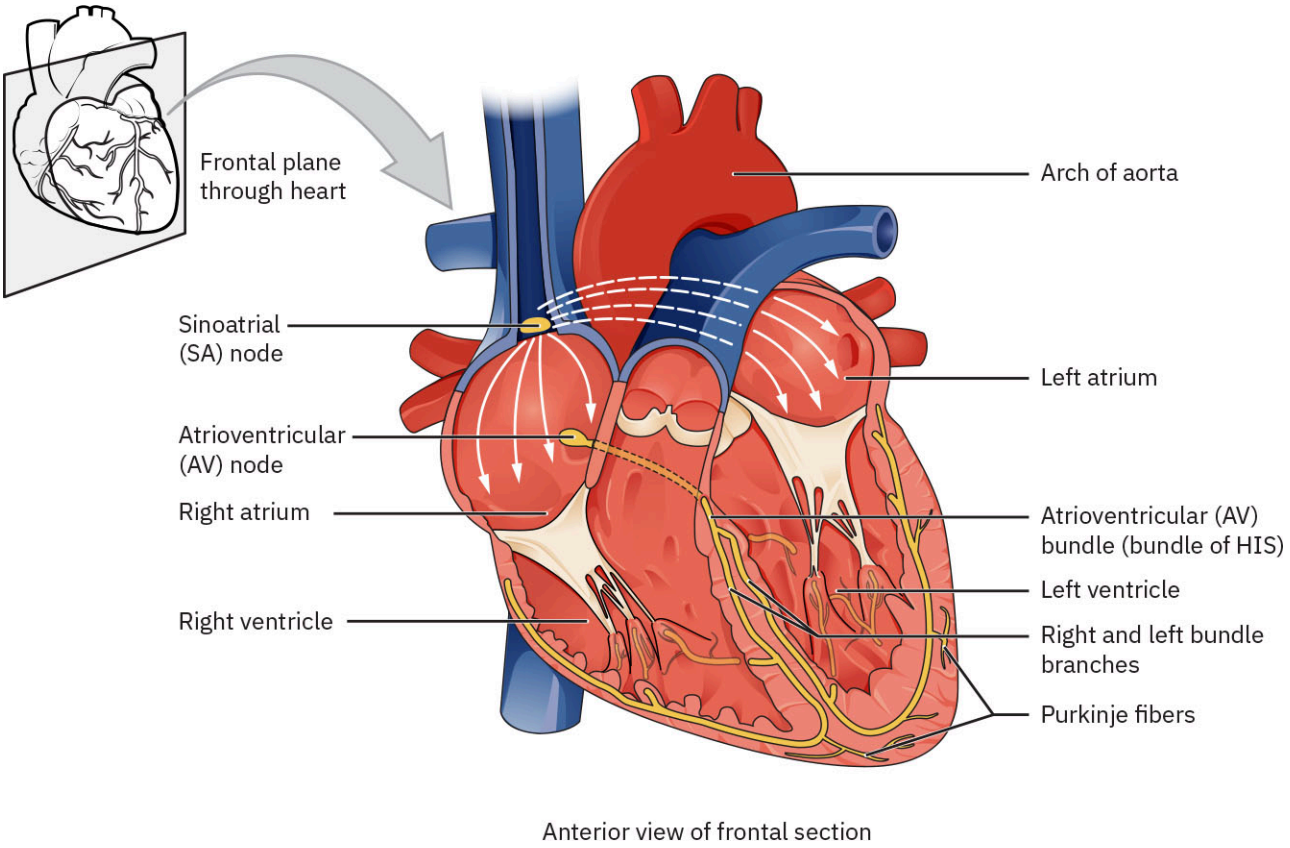

FIGURE 12.4 Electrical pathways originate in the sinoatrial node, travel through the atria and into the atrioventricular junction, down the Purkinje fibers, into the left and right bundle branches, and cause a contraction. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

When a patient has dysrhythmia, the normal cardiac conduction process is interrupted. Two mechanisms are occurring and not in synchronicity. As the right and left ventricles fill with blood, the atria contract to inject blood into those respective ventricular chambers (diastole). Once the ventricles are adequately filled, the tricuspid and mitral valves open, the semilunar valves close, and blood is pushed from the ventricles into the lungs and systemic circulation (systole). Continuous cardiac telemetry analysis was not introduced into the acute care setting until the 1960s, reserved for higher levels of care such as intensive care units (Chen et al., 2018). With this advancement in

technology, close monitoring of patients experiencing dysrhythmias was more possible. However, to fully understand dysrhythmia identification, intervention, and nursing care, the nurse needs to understand rhythm analysis.

Rhythm Interpretation

The **normal sinus rhythm**, or the rhythm that originates from the sinus node and describes the characteristic rhythm in the healthy human heart, includes several features (Figure 12.5). The first small, round hill observed is called the P wave. The P wave represents electrical depolarization, or the channeled travel of electricity, in the atria, whereas the QRS complex, a jagged triangular shape, represents electrical current traveling through the ventricle. An **atrial depolarization** is represented by the interval between the P wave and the R wave in the QRS complex; this is a measurement of the time needed for electricity to travel from the atria to the ventricles. Normal criteria for the PR interval are 0.16 to 0.20 seconds. A **ventricular depolarization** is the measurement of the time electricity travels through the ventricles to conduct a ventricular contraction and is represented by the QRS complex. It is shorter in duration compared to the PR interval, less than 0.12 seconds. Figure 12.5 summarizes these times.

FIGURE 12.5 This normal sinus rhythm shows a P wave, preceding the QRS, followed by the T wave. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

To capture measurements of these electrical travel times, a nurse may use calipers to measure the distance between the P wave and the R wave or the space in the QRS complex (Figure 12.6). However, the most common method used is measuring boxes in a telemetry strip. It is important to note that in each large box are five small boxes. Each small box represents 0.04 seconds, and each large box represents 0.20 seconds.

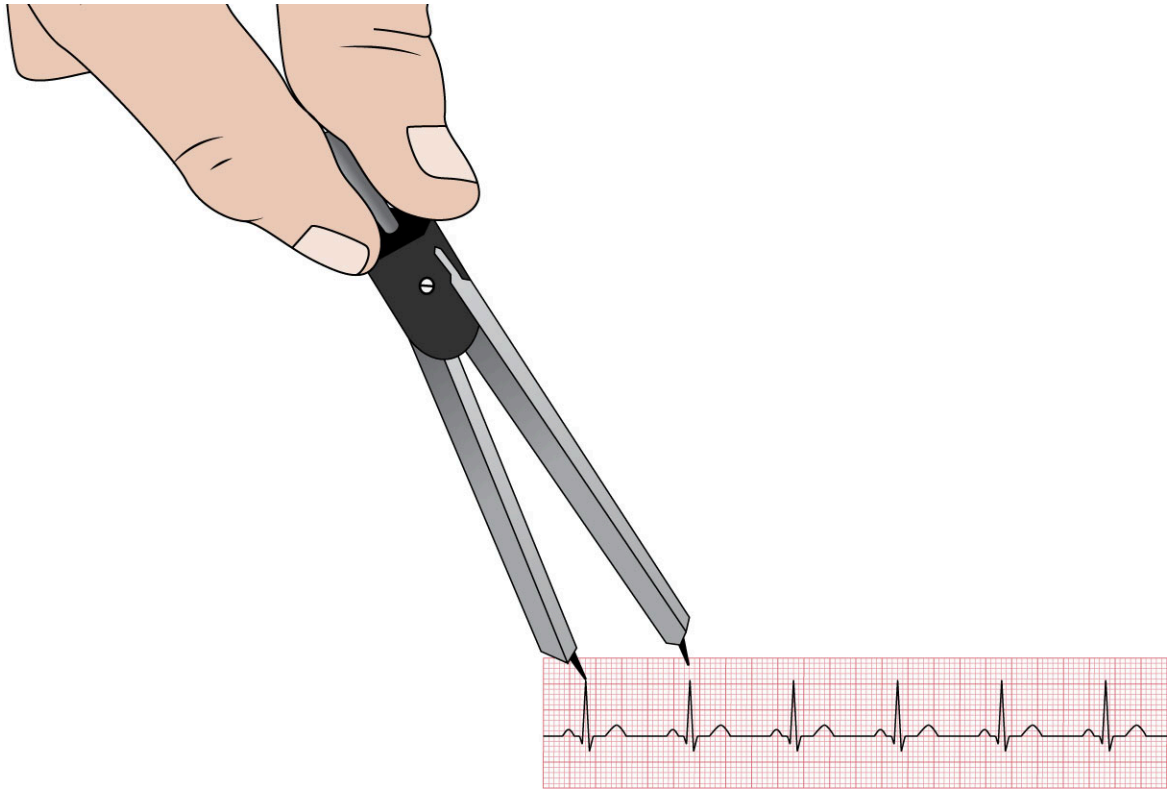

FIGURE 12.6 Telemetry calipers may be used to measure several interval distances, such as the distance between the P wave and the R

wave, the space in the QRS complex, or the distance between R waves, as seen here. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

In addition to normal measurements for the PR and size of the QRS complexes, regularity and rate must be established. A 6-second strip is required to determine these features. The nurse must "march out" with calipers or by tracing the P-to-P waves to evaluate regularity, or whether beats are occurring at regular intervals. One comparison would be the regular tempo of music: is it regular and is the beat predictable? The same applies to cardiac conduction. If there is regularity between the P-to-P waves and R-to-R waves, this is deemed a regular rhythm.

The second measurement is the heart rate, which normally falls between 60-100 beats per minute (bpm) (Table 12.1). The fastest method to obtain heart rate is to count the number of QRS complexes in a 6-second strip and multiply that number by ten. For instance, if the nurse counts seven QRS complexes in a 6-second strip, the ventricular rate is approximately 70 beats a minute. For a more accurate assessment of heart rate, the nurse can count the number of large or small boxes occurring between the R-to-R complexes if regularity has been established. Once the number of small boxes or large boxes have been determined, the constant used for division is 300 seconds ÷ number of large boxes or 1500 seconds ÷ number of small boxes. For instance, if the nurse counts 20 small boxes from the R-to-R interval, 1500 seconds ÷ 20 small boxes will yield a heart rate of 75 beats.

Cardiac Rhythm Component	Description	Normal Interval
P wave duration	Time for atrial depolarization	0.06–0.12 seconds
PR interval	Time from the start of atrial depolarization to the start of ventricular depolarization	0.12–0.20 seconds
QRS duration	Time for ventricular depolarization	0.06–0.10 seconds Greater than 0.12 seconds is considered abnormal and "wide"
QT interval	Time from the start of ventricular depolarization to the end of ventricular repolarization	0.36–0.44 seconds
ST segment	Period between the end of ventricular depolarization and the start of ventricular repolarization	Typically isoelectric (flat)
T wave duration	Time for ventricular repolarization	Variable; typically follows the ST segment
RR interval	Time between successive R-wave peaks	Variable; dependent on heart rate
Heart rate (HR)	Derived from RR interval; the number of beats per minute	60-100 beats per minute (BPM)

TABLE 12.1 Normal Intervals in Cardiac Rhythms

CLINICAL SAFETY AND PROCEDURES (QSEN)

Safety: Telemetry Monitoring

Definition: Reducing the risk of patient harm through effective system and individual action.

Knowledge: Identify the benefits and limits of safety-enhancing technologies (e.g., barcodes, Computer Provider Order Entry, medication pumps, and automatic alerts/alarms).

Skill: Effectively use technology and standardized practices that promote safety and quality. To demonstrate competence, the nurse will:

- Follow institutional practices for the use of telemetry monitoring, which may include:
  - Setting and maintaining alarms per policy and order
  - Using alternative devices (such as wireless monitors) for ambulation or transportation for patients unable to be removed from monitor
  - Carrying a pager or device on your person to receive alerts
  - Physically assessing the patient's status and apical heart rate in response to alerts

Attitude: Understand and appreciate how standardization and reliability contribute to safety.

(QSEN Institute, n.d.)

Bradycardic and Tachycardic Dysrhythmias: Clinical Manifestations and Nursing Care

Normal heart rates are 60 to 100 beats per minute (bpm). There are normal fluctuations in heart rate, including lower heart rates with relaxation, medication, and during sleep. During peaks of productivity, exercise, or even illness, such as infection, the heart rate may increase.

Bradycardic rhythms are rates less than 60 bpm (Figure 12.7). Features of **sinus bradycardia** are a rate less than 60 bpm, with regular PR and QRS intervals.

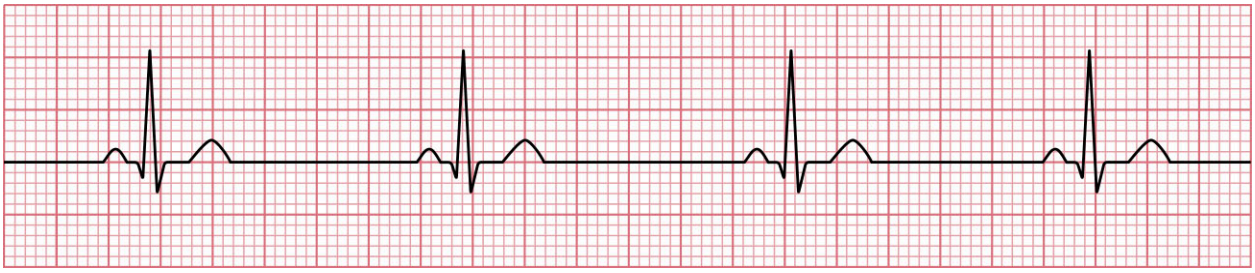

FIGURE 12.7 Sinus bradycardia is a heart rate of less than 60 bpm. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Sinus bradycardia may occur due to medications, such as beta-blockers, digoxin, or opioids, or increasing vagal tone from bearing down. Patients may be asymptomatic, or report fatigue, dizziness, or weaknesses. For cues to be recognized, it is imperative for the nurse to inquire about the patient's level of activity. In some patients, a resting heart rate of less than 60 bpm may be a clinical finding in an active runner. Nursing interventions for symptomatic patients include holding cardiac medications if pulse is less than 60 bpm (alert the provider), having the patient stay in bed as the patient may be lightheaded or dizzy, and continuing to monitor the patient. The provider may also order medications to raise the heart rate (such as atropine) or initiate **transcutaneous pacing**, a noninvasive procedure that uses electrical impulses to temporarily pace a patient's heart.

LINK TO LEARNING

Atropine is an anticholinergic that can be administered intravenously to correct symptomatic bradycardia. Side effects include decreased gastric secretions, drying of mucus membranes, and increased esophageal sphincter tone. Read more about atropine (https://openstax.org/r/77Atropine) at StatPearls.

In contrast, tachycardic rhythms are rates greater than 100 bpm (Figure 12.8). Features of sinus tachycardia are a rate greater than 100 bpm with regular PR and QRS intervals.

FIGURE 12.8 Sinus tachycardia is a heart rate greater than 100 bpm. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Factors contributing to tachycardia may include stress, dehydration, fever, exercise, caffeine, or illegal substances such as cocaine or stimulants. Clinical manifestations may include shortness of breath, anxiety, fluttering, flushed face, or dizziness, but the patient may also be asymptomatic. Interventions include rest, fluids, treatment of the underlying cause, medications, such as beta blockers, and monitoring hemodynamics.

Ectopic Beats: Clinical Manifestations and Nursing Care

An occasional, singular, irregular beat, also known as an **ectopic beat**, may originate from the atria or the ventricles (Figure 12.9). Atrial ectopic beats will cause an early, irregular occurrence of P and QRS waves; this is called a **premature atrial contraction (PAC)**. In contrast, a **premature ventricular contraction (PVC)** is when a ventricular ectopic beat appears without a P wave and widens the appearance of the QRS. If there are frequently occurring ventricular beats that all look the same, they are unifocal, or uniform; if they look different, they are multifocal, or multiform.

A compensatory pause after a PVC occurs as the heart's natural response to the early, irregular beat; this pause allows the heart to reset its rhythm and ensures that the subsequent beat falls in line with the normal rhythm, thereby helping to maintain overall cardiac rhythm stability. A non-compensatory pause following a PAC occurs because the premature beat disrupts the regular cardiac cycle, causing a brief interruption in the normal rhythm without a full reset of the heart, which results in a shorter pause before the next beat compared to a compensatory pause.

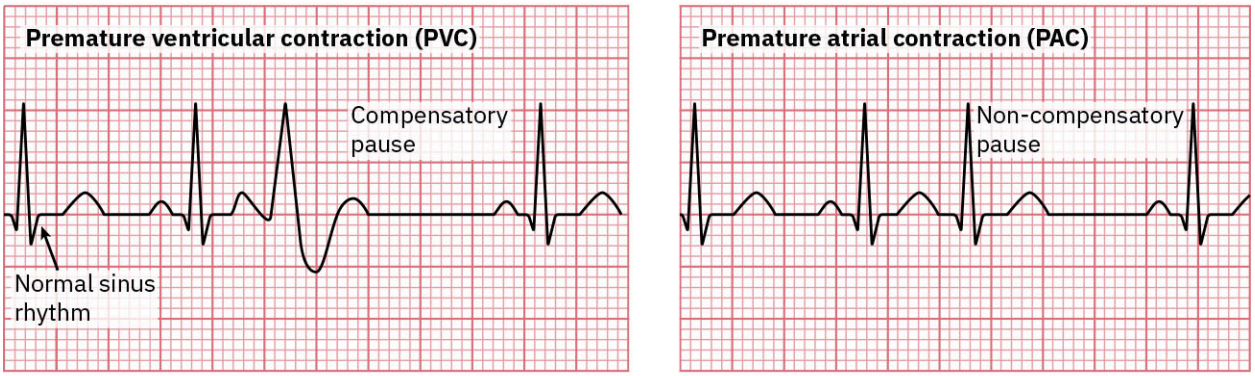

FIGURE 12.9 (a) A PVC is an early, wide-appearing QRS without a P wave, followed by a compensatory pause. (b) A PAC is an early occurrence of a P and QRS wave, followed by a non-compensatory pause. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The frequency of the ectopic beat may vary. An ectopic beat occurring on every other beat is bigeminy; an ectopic beat occurring on every third beat is trigeminy. When there are more than three PVCs in a row, this is called a run of ventricular tachycardia, which is a potentially life-threatening cardiac dysrhythmia that occurs when the lower chambers of the heart beat too fast to pump well.

Ectopic beats may be triggered by drugs, caffeine, alcohol, stress, electrolyte disturbance, or certain medications. Patients may experience few to no symptoms with occasional ectopic beats. However, ectopic beats that occur more frequently will cause symptoms. Clinical manifestations include subjective complaints of dizziness, palpitations, fluttering in the chest, adjusting of heart rate, or chest pain. Nursing interventions include having the patient remain calm and do some deep breathing, administering cardiac medications/electrolyte replacement as ordered, and monitoring the patient's vital signs. It may be necessary to check laboratory values to assess for abnormal potassium, calcium, or magnesium levels. The patient should be instructed to avoid caffeine and alcohol,

as these may trigger more ectopic beats.

2. What is an expected finding?
3. What interventions should the nurse take?

Heart Blocks: Clinical Manifestations and Nursing Care

Another commonly occurring dysrhythmia is heart block, in which there is an impulse interruption between the atria and ventricles, called an atrioventricular (AV) block, or heart block. There are three types of heart block: first-degree heart block (Figure 12.10); second-degree, further broken down into Type I and Type II; and third-degree heart block. In **first-degree heart block**, the PR interval is consistently greater than 0.20 seconds (Table 12.1), while QRS is normal and regular. Patients are often asymptomatic, and it is often found incidentally. First-degree heart block may be due to medications, increased vagal tone, or family heart disease. It is the nurse's responsibility to monitor for worsening symptoms. However, most patients live with first-degree heart block without complication.

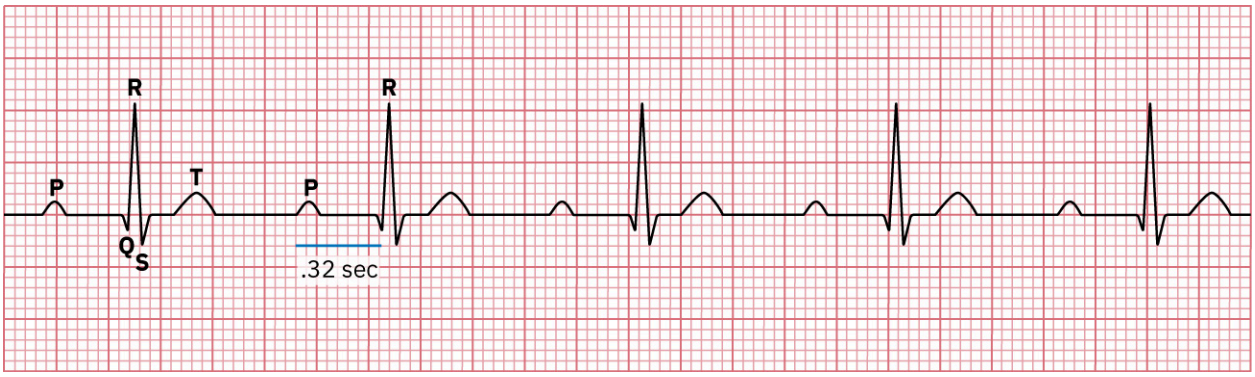

FIGURE 12.10 PR intervals in a normal sinus rhythm should be between 0.12 to 0.20 seconds long. Here, the measurement of the PR interval is greater than 0.20 seconds, indicating a first-degree heart block. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

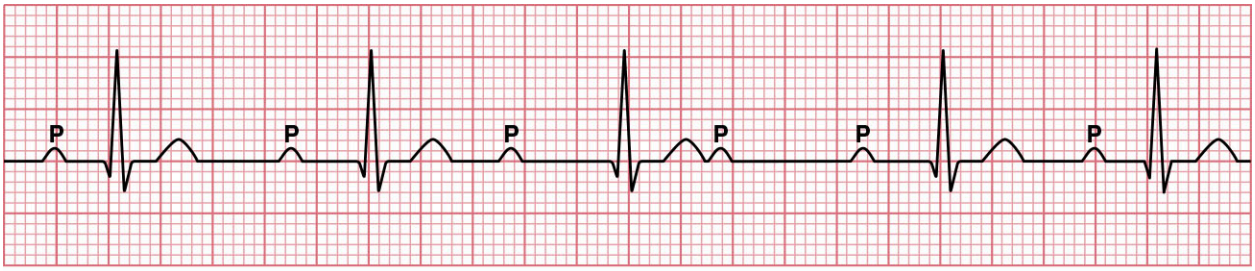
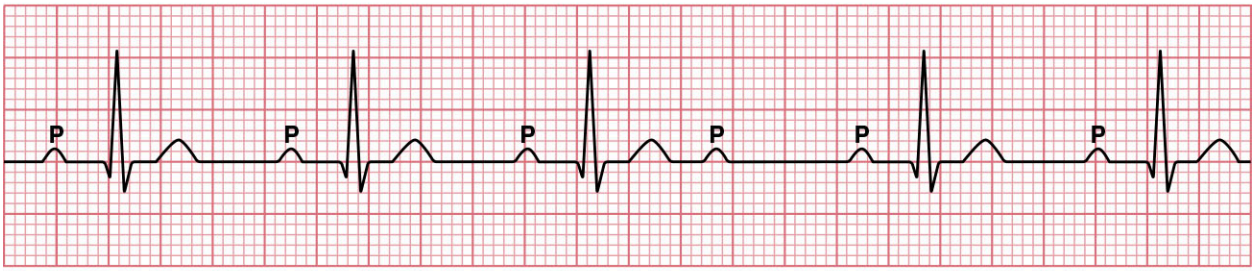
Second-degree heart block is further broken down into two parts: Type I (also known as Mobitz I or Wenckeback) and Type II (Mobitz II) (Figure 12.11). With **Mobitz I second-degree heart block**, the classic features are a PR interval that gets longer with each beat until a QRS is dropped, and the pattern repeats. In contrast, in **Mobitz II second-degree heart block**, the PR interval is constant, and some of the QRSs are blocked. This does not occur in a pattern like Mobitz I. Mobitz II heart block is more serious and can potentially lead to third-degree heart block. With Mobitz I, the patient may be asymptomatic. Other complaints, more consistently, from Mobitz II, are dizziness, fatigue, chest pain, shortness of breath, or the subjective feeling of a skipped beat. Typical causes of second-degree heart block may be medications, underlying heart disease, or an aging conduction system.



(a)



(b)

FIGURE 12.11 (a) In Mobitz I second-degree heart block, the PR interval gets progressively longer until a QRS is dropped; the pattern repeats. (b) In Mobitz II second-degree heart block, the PR interval remains constant, but some of the QRSs are randomly dropped. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Nursing responsibilities include telemetry monitoring, trending the blood pressure, or if the patient becomes more symptomatic (for example, becomes hypotensive, complains of increased chest pain or dizziness), administering an anticholinergic such as atropine to transiently raise the heart rate. The patient may require transcutaneous pacing and be prepared for surgery for a **pacemaker**, a small implantable machine with a battery life of approximately ten years that recognizes when the heart rate is too fast or too slow and will pace the rhythm to a preset range (e.g., a heart rate of 60 to 70 bpm) to meet perfusion needs (Figure 12.12). Patients with pacemakers must be instructed to carry a card for passage through metal detectors and to avoid direct exposure to microwaves as these appliances can compromise the device's battery. The presence of a pacemaker should be identified for safety with MRI.

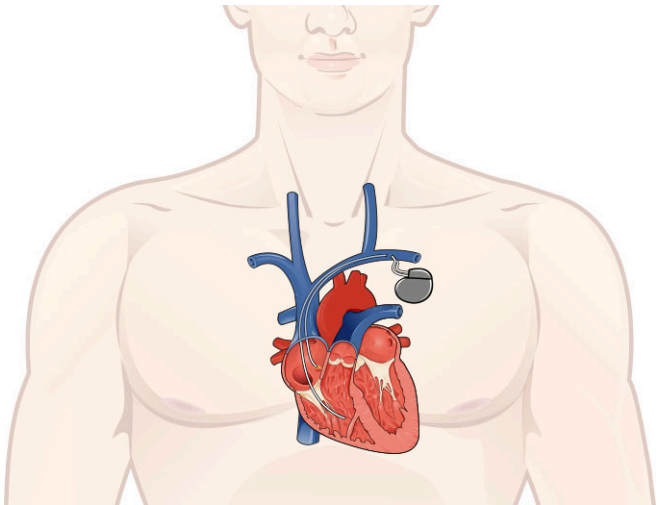


FIGURE 12.12 Pacemaker wires are threaded into the veins and detect slow heart rhythms and pace the slow rate into a normal rate. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

A **third-degree heart block** is the most serious heart block as there is a loss of electrical impulses between the atria and the ventricles (Figure 12.13). In essence, the ventricles must beat independently to maintain cardiac output. In contrast to myocyte contractility rates in the atria, the ventricular tissue has a slower impulse control with a rate of 20 to 40 bpm. P-P and R-R intervals are variable. Atrial and ventricular rates will differ drastically. Also, the QRS interval is wide, greater than 0.12 seconds. The patient will report feeling lightheaded, dizziness, fatigue, chest pain, or may have a syncopal episode and hypotension.

FIGURE 12.13 With third-degree heart block, the P waves are not related to the QRS complexes, showing that the atria are electrically disconnected from the ventricles. The QRS complexes represent an escape rhythm arising from the ventricle. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Third-degree heart block requires quick intervention. Nurses must apply telemetry to the patient and prepare for transcutaneous pacing, assess oxygenation, check labs to alert the provider if there are any electrolyte shifts (potassium or magnesium), maintain bed rest, and hold antiarrhythmics/beta blockers. Patients will require a pacemaker.

Atrial Dysrhythmias: Clinical Manifestations and Nursing Care

The most common rhythm disturbances occur in the atrial tissue. A popular umbrella term utilized to discuss rhythm disturbances that occur above the ventricles is **supraventricular tachycardia (SVT)** (Figure 12.14). The most common forms of SVT are **atrial fibrillation (AFib)** and atrial flutter. AFib is an irregular, fast rhythm originating from the atria due to multiple impulses being fired. The CDC (2022) predicts that by 2030, 12.1 million people in the United States will have AFib. The telemetry qualifiers are regularly irregular, the PR interval is indeterminate due to the irregularity, and the QRS interval is less than 0.12 seconds. AFib is considered rate controlled if the rate is between 60 and 100 bpm, or rapid when rates consistently climb over 100 bpm.

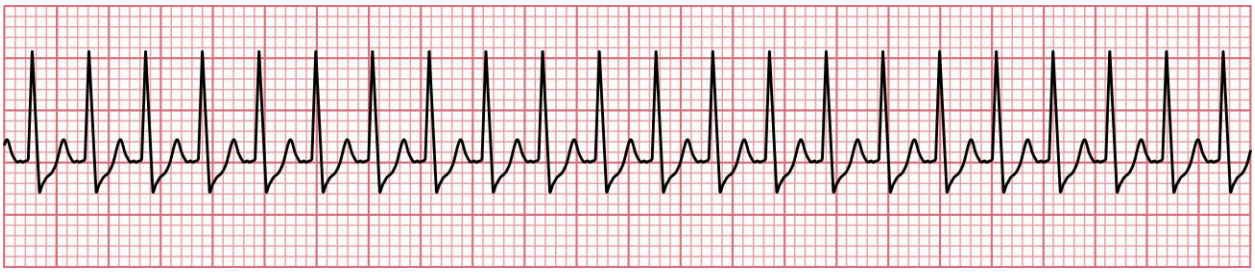

FIGURE 12.14 With supraventricular tachycardia (SVT), the P waves are difficult to distinguish, and without P waves, the PR interval is nonexistent. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

An **atrial flutter (A flutter)** is an atrial dysrhythmia related to AFib (Figure 12.15). It is a regular but tachycardic rhythm caused by electrical re-entry in the right atrial circuity. The classic "saw tooth pattern" is one of the hallmark features. The PR interval is indeterminate, the QRS interval is less < 0.12, and it is regular. A flutter rates may be 240 to 300 bpm.

FIGURE 12.15 This saw-tooth pattern is classic of A flutter. This rhythm shows a 4:1 ratio, meaning that there are four flutter waves per every QRS complex. There are no discernible P waves. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The clinical manifestations of AFib and A flutter are very similar in nature; therefore, it is difficult to isolate which dysrhythmia is occurring based on symptom presentation only. Patients will report fluttering sensations, chest pain, palpitations, and dizziness, and may experience hypotension. The faster the tachycardia, the more severe the patient's symptoms will be.

Nurses must assess and evaluate the need for additional oxygenation support and monitor telemetry and vital signs.

The patient may need to refrain from eating to prepare for cardioversion (a procedure performed by a machine or medicine that restores a normal heart rhythm when the heart is beating too fast or irregularly) or ablation **(**a procedure that creates scars in the heart tissue which block the abnormal electrical impulses to help the heart maintain a normal rhythm). First-line therapies lean towards pharmacological therapies, which include digoxin, beta-blockers, amiodarone (cardiac glycosides), and calcium channel blockers (CCBs). Other concurrent therapies considered are anticoagulants for atrial dysrhythmias. Patients with comorbid congestive heart failure, hypertension, age over 65, stroke and diabetes, and AFib would require anticoagulation with heparin, warfarin, or the new oral anticoagulants (NOACs).

CLINICAL SAFETY AND PROCEDURES (QSEN)

Safety: Preparing the Patient for Cardioversion

In events where the patient's atrial dysrhythmia is non-responsive to pharmacological therapies, cardioversion is a procedure in which electricity is utilized to shock the atrial circuitry back to normal sinus rhythm. The dose of electricity varies by patient and provider preference; it may be as little as 50 joules to up to 100 to 150 joules.

1. The patient must be nothing by mouth (NPO) as monitored anesthesia care (MAC) is required, and to mitigate the risk of aspiration, the patient is advised to not have any solids before the procedure.
2. Prior to cardioversion, a transesophageal echocardiogram will be performed to isolate any possible blood clots that may be hiding in the atrial appendage. This diagnostic test is necessary because if there is an isolated blood clot and the patient is cardioverted, the clot can be expelled to the brain or lungs, risking a cerebrovascular accident or pulmonary embolism.
3. The nurse must ensure that the transcutaneous pads are connected correctly and that the defibrillator is turned to the "cardioversion" setting. The cardioverter will synchronize the shock delivery with the patient's QRS on their EKG rhythm. (Delivery of an unsynchronized shock risks sending the patient into cardiac arrest.)
4. After the delivery of the provider-ordered electricity, the nurse will monitor the patient's response to the cardioversion and note if the patient returned to a normal sinus rhythm.
5. Post-procedure, the patient will be monitored for a period of two hours, noting hemodynamics, rhythm response, and the patient's response to monitored anesthesia care.

Ventricular Dysrhythmias: Clinical Manifestations and Nursing Care

Ventricular disturbances are the most serious dysrhythmias and require prompt, emergent intervention. A **ventricular tachycardia** is when the ventricle beats rapidly at 150 to 200 bpm with wide QRS complexes (greater than 0.12 seconds) and no discernible PRs or P waves (Figure 12.16). A **ventricular fibrillation** is slightly faster than ventricular tachycardia with rates over 200 bpm (Figure 12.17). A classic finding in ventricular fibrillation is a chaotic baseline with no discernible QRS, PRs, or P waves. Patients with ventricular tachycardia may be able to report subjective feelings of fluttering, fatigue, and near syncope. The patient will be diaphoretic and have weak pulses. In severe cases, they can lose perfusion and have syncope. Ventricular fibrillation is considered a cardiac arrest as patients will lose consciousness and require advanced cardiac life support. Causation of these dysrhythmias can be from myocardial infarction, heart failure, electrolyte disturbance, illegal substance abuse, shock, or medications.

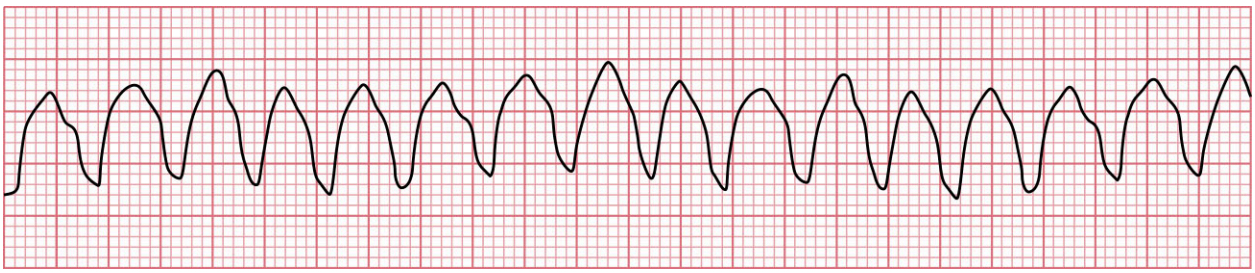

FIGURE 12.16 In ventricular tachycardia, the rate is fast, there are no discernible P waves, and the QRS is wide. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

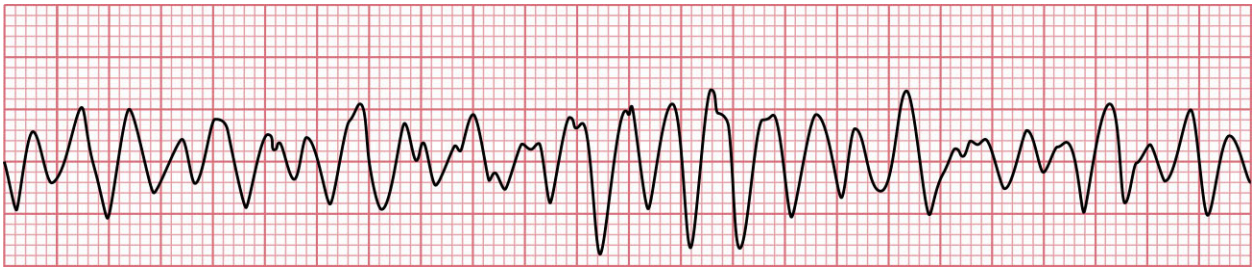

FIGURE 12.17 In ventricular fibrillation, there is no pattern, it is fast, there are no discernible P waves, the QRS waves are not well captured, and there is variation in the morphologies of the QRS complexes. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The nurse must act quickly when ventricular tachycardia or ventricular fibrillation is occurring and recruit assistance as outcomes of survival increase with prompt intervention. Nursing actions include performing high-quality cardiopulmonary resuscitation (CPR) for pulseless ventricular tachycardia and pulseless ventricular fibrillation, utilizing an automated external defibrillator, and providing oxygen. When a pulse is present, only other restoration methods can be used. Restoration of perfusion is a team approach and requires health professionals to provide CPR, defibrillation, and oxygen, and to administer emergency medications (e.g., epinephrine, amiodarone, calcium gluconate). Once hemodynamic stability has been achieved, nursing interventions center around patient monitoring, laboratory trending, and implementing a clinical plan dependent on the cause.

CLINICAL SAFETY AND PROCEDURES (QSEN)

Safety: Interventions with CPR and the Defibrillator for Ventricular Fibrillation

1. The code team is activated per institutional policy.
2. High-quality CPR with a compression rate of 100 to 120 compressions per minute (note there is a full recoil of the chest at a depth of two inches). It is of utmost importance to step out after five cycles (two minutes) of CPR as rescuers may experience fatigue. This safety "tap out" is necessary to continue high-quality CPR until the return of spontaneous circulation.
3. The AED is retrieved, and pads are placed to initiate a dose of electricity. The machine will determine if a shock is advised and will prompt all rescuers to step away to avoid being shocked.
4. A team member begins bagging the patient with bag valve mask of 100% oxygen.
5. Medications may be administered during resuscitative efforts such as epinephrine, amiodarone, and lidocaine.
6. Assess for a carotid pulse and resume CPR if no pulse is palpated.
7. The longer the delay to high-quality CPR, the higher the mortality rate. To maximize outcomes, initial intervention should occur within the first three minutes of a witnessed cardiac arrest. In an acute care setting, members from the intensive care unit, emergency room, and respiratory therapy will assist in rescuing interventions. When the code team arrives, they will initiate advanced cardiovascular life-support (ACLS) following the protocol set forth by the American Heart Association.

Asystole

Lastly, there is **asystole**, also known as ventricular standstill, or "flatline" (Figure 12.18) (Jordan et al., 2024). Cardiac activity ceases to occur due to termination of electrical conduction. Clinical signs of asystole are determined by the rhythm showing a flat line with little to no evidence of cardiac rhythm.

FIGURE 12.18 The rhythm here begins as bradycardic and the T waves are not captured, until the strip goes flat, with no evidence of atrial or ventricular activity, indicated asystole. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The mortality of asystole is approximately 90 percent (Khosla et al., 2024), with long term complications of brain death and high-demand needs for artificial life support. Asystole is often linked to unsuccessful attempts to correct bradycardia dysrhythmias, ventricular dysrhythmias, or pulseless electrical activity (Jordan et al., 2024). Like the presentation of ventricular fibrillation, the patient will be unconscious, with no evidence of breathing, weak pulses, and a low blood pressure that is unable to support cardiac physiological demands. Nursing actions align with a team member's roles in attempts to restore spontaneous circulation, performing high-quality CPR, administration of epinephrine, and airway protection with intubation or bag-mask ventilation. The advanced cardiovascular life-support providers will then attempt to determine the cause of the asystole by investigating the "Hs and Ts."

LINK TO LEARNING

Advanced cardiovascular life-support providers investigate the "Hs and Ts" (https://openstax.org/r/77Dysrhythmia) which are the twelve reversible causes of life-threatening dysrhythmias.

Evaluation of Nursing Care of the Patient with Dysrhythmia

Depending on the patient's dysrhythmia, stabilization of cardiac perfusion is a key component through normalization of heart rate and blood pressure. The patient's oxygenation will improve following stabilization of the dysrhythmia as evidenced by oxygen saturations greater than 92 percent and reduced complaints of shortness of breath. The patient's energy level will improve as evidenced by the ability to participate in self-care activities. Lifestyle modifications (e.g., smoking cessation, altered diet, weight management) and compliance with pharmacological therapies can control or minimize the effects of dysrhythmia. The patient's educational needs will vary depending on medical therapy and verbalized understanding of the condition, treatment, and interventions initiated (e.g., if the patient had a pacemaker).

Dysrhythmia management may pose challenges, as telemetry analysis is a skill that takes time to learn. Over time, the nurse will become more proficient and confident in the ability to identify and intervene when a dysrhythmia is observed. Acute care settings with cardiovascular specialty or medical-surgical units with a high level of care have institutional mentorship and programs to assist new nurses with skill mastery. The baseline of a strong foundational understanding of cardiovascular electrical physiology will assist the nurse with matching the dysrhythmia to symptom presentation.

INTERDISCIPLINARY PLAN OF CARE

Roles and Responsibilities of Pertinent Team Members During Cardiac Arrest

- Respiratory therapy: Respiratory therapists assist manually ventilating patients with a bag valve mask and assisting anesthesia or the health-care provider with intubation.
- Physicians/health-care providers: Providers typically take lead roles in ordering pharmacological interventions or diagnostics during cardiac arrest.
- Nursing: Nursing roles are diverse in the administration of emergency medications, recording the events of the cardiac arrest, and performing CPR.
- Pharmacists: Pharmacists will ensure doses and frequency of pharmacological therapies are safe and alignment with Advance Cardiovascular Life Support (ACLS) algorithms.
- Chaplain/social work: Religious and social support have become more popular in extending spiritual and emotional support to the patient's loved ones.

12.3 Heart Failure

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations of heart failure
- Describe the diagnostics and laboratory values in the disease of heart failure
- Apply nursing concepts and plan associated nursing care for the patient with heart failure
- Evaluate the efficacy of nursing care for the patient with heart failure
- Describe the medical therapies that apply to the care of heart failure

A chronic condition that reduces perfusion to the body because the heart is working inefficiently is known as **congestive heart failure (CHF)**. It is sometimes more simply referred to as heart failure (HF). HF not only affects quality of life but is costly in dollars and mortality. There are currently 6.2 million adults in the United States with congestive heart failure, costing the nation $30.7 billion each year (CDC, October 14, 2022).

Both modifiable and nonmodifiable risk factors have been identified for HF. Nonmodifiable risk factors include gender, age, and family history, whereas modifiable risk factors encompass certain lifestyle practices. The National Heart, Lung, and Blood Institute (2022) identified a myocardial infarction as a concurrent comorbidity that elevates the risk of developing HF. Damage to the heart muscle itself puts a person at risk for developing HF. Individuals who consume a diet high in sodium and fat, smoke, drink excessive alcohol, and are physically inactive have a propensity for heart disease. Disease prevalence of HF occurs in 65 percent of individuals with high blood pressure, 50 percent of individuals with ischemic heart disease, 41 percent of patients with atrial fibrillation, and 27 percent of individuals with diabetes mellitus (Lawson et al., 2020). Gender does not appear to be a factor, as the occurrence of HF is similar between females and males (Lam et al., 2019). Ethnicity does, however, impact the risk of developing HF, as Black people and Hispanic people have a higher occurrence of HF compared to White people (Breathett, 2020). Given the propensity of disease, nurses are tasked to understand the complexity of CHF and the lifespan considerations that apply to the patient.

Pathophysiology

The human heart delivers between two to four liters of newly oxygenated blood each minute from the left ventricle into the aorta and into the circulating blood supply. Oxygen-rich blood pulses through the blood vessels to supply tissues and cells with necessary nutrients for cellular metabolism. However, HF causes weakness in the ventricular muscle, resulting in lower pressure and thereby impeding the forward flow of blood. A fundamental understanding of myocardial physiology is necessary to understand HF. Recall that preload is the amount of stretch myocardial cells confront prior to contraction, or ventricular filling. In contrast, afterload is the force of blood the ventricle must overcome to eject the blood. A compensatory thickening of the ventricle, often referred to as **left ventricular hypertrophy**, ensues due to increased myocardial stretch from increased pressure resulting from uncontrolled high blood pressure. Over time, the myocardial muscle of the ventricle fatigues and struggles to maintain optimal pressures of blood and fluid. Consequently, valves become incompetent and create backflow of blood into the pulmonary and hepatic systems.

The American Heart Association (2022) differentiates classifications of right-sided heart failure and left-sided heart failure. A **right-sided heart failure** results when increased fluid pushes fluid back into the pulmonary system, and congests the right side of the heart, causing the right ventricle to fail. In contrast, **left-sided heart failure** develops when the left ventricle muscle is damaged and weak and can no longer pump enough blood through the body. Left-sided HF is further divided into systolic and diastolic failure (Figure 12.19). (See Figure 12.2 for the normal cycle of blood circulation.) Systole is ventricular contraction and the period in the cardiac cycle when blood is ejected from the ventricles into the lungs and aorta. Systolic failure results when the diseased ventricle is unable to eject blood forward, creating a backward flow. Diastole represents ventricular filling, caused by atrial contraction. With diastolic dysfunction, the ventricle is stiff and thick and cannot fully relax. As a result, inadequate filling of the chamber occurs.

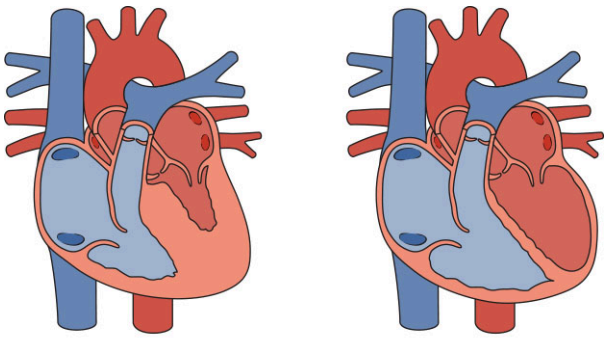

FIGURE 12.19 Left-sided heart failure is divided into diastolic and systolic heart failure. (a) Diastolic heart failure is indicated by thick heart walls. (b) Systolic heart failure is indicated by thin heart walls. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

HF can cause damage to other body systems when blood volume and flow to essential organs decreases. HF may impair the ability of the kidneys to appropriately excrete sodium and water as blood volume decreases in the kidneys. A nurse must understand the causes, clinical manifestations, diagnostic tests, medical treatment plans, and patient education for the patient with HF to help the patient achieve optimal outcomes.

Clinical Manifestations

The classic presentation of HF includes lower extremity edema, weight gain, cough, sputum production, and alterations in hemodynamics. Patients with fluid retention may have observable swelling in their digits and lower extremities. The patient may offer subjective complaints of poorly fitting socks, shoes, pants, or rings.

Upon assessment of the patient with HF, note any indentations from socks or shoes. Gently palpate the lower extremities observing for pitting or depth of residual finger marks, then grade it from 0 (no edema) to 4+ (pitting edema) (see Figure 10.9). Patients with edema often will have an elevated weight. It is best practice to have the patient void in the morning before obtaining weight, in the same garments or nude if possible. Weight gain of three pounds in a day or five pounds in a week is suggestive of HF. Other hemodynamic deviations may include blood pressure elevation due to fluid retention.

A recommended practice for the nursing assessment of HF is evaluating the patient's airway, breathing, and circulation (ABCs). The nurse may observe **dyspnea**, or difficulty breathing, or it may be reported by the patient. The nurse may observe, or the patient may report, breathlessness while completing activities of daily living. Patients may allude to difficulty sleeping due to struggles with breathing while lying flat, also called **orthopnea**. The patient may complain of the need to sleep on more than two pillows or upright in a recliner. Other assessment findings may be a frothy pink sputum or a productive wet cough. Oxygen saturation may be less than 92 percent due to fluid backing up into the pulmonary system. A lung assessment may reveal crackles in the pulmonary bases. The patient with HF may have some or all these findings; however, patients with pulmonary edema will demonstrate respiratory distress.

The nurse should inquire if the patient is experiencing any chest pain. Chest pain occurs due to poor coronary perfusion and could result from a previous myocardial infarction. The nurse should employ an organized, detailed manner when assessing the patient's chest pain. Utilization of the PQRST mnemonic is a recommended model to detail the patient's chest pain:

- P: what provokes or relieves the chest pain (chest pain from poor coronary perfusion is exacerbated by activity and relieved by rest),
- Q: what is the quality of your pain (chest pain from ischemia is described as a dull ache in the chest or in the arms),
- R: what region and does it radiate,
- S: have the patient identify the severity of pain, and
- T: timing, when did it begin? The patient may be experiencing ischemic chest pain or a myocardial infarction.

In addition to performing a thorough pain assessment, the nurse must determine if the patient is experiencing any fatigue, or tires easily during activities of daily living. Patients with HF have deficits with adequate perfusion, and reduced cardiac output can interfere with energy reserves. Due to poor ventricular blood output, the patient may

experience dizziness or palpitations. Lack of perfusion to the brain may manifest with dizziness or episodes of syncope from triggered tachycardic dysrhythmias that result from ventricular failure. As HF progresses with ventricular remodeling and weakening of the heart muscle, cardiac cells change and are more "excitable," making the patient vulnerable to tachycardic dysrhythmias. It is imperative the nurse shares with the provider the frequency of symptoms, as this suggests the severity of the disease.

Diagnostics and Laboratory Values

A comprehensive diagnostic and laboratory workup is indicated when there is a suspicion of HF. The gold standard for detecting HF is ultrasound visualization via **echocardiogram**. This digital image offers visualization of valve competency, filling pressures, measurements of ventricular thickness, and compliance of the ventricles. Coronary artery disease or blockages that prevent perfusion of the myocardium can cause HF. Diagnostic workup for coronary artery disease includes conducting an **electrocardiogram**. These tracings can detect a coronary blood defect or evidence of injury from myocardial infarction. Nuclear stress tests utilize radioactive isotopes to assess coronary patency.

The **ejection fraction** is a measurement of ventricular compliance that is obtained through an ultrasound done of the heart. In a healthy heart, the left ventricle's ejection fraction is 55 to 60 percent. A hyperdynamic ejection fraction exceeding 70 percent is strongly correlated with diastolic dysfunction and means the ventricle is overcompensating for a diseased ventricular muscle. Conversely, patients with ejection fractions less than 40 percent have a higher risk for developing serious dysrhythmias.

With a new diagnosis of HF, the suspicion of coronary artery disease is high and must be investigated. More invasive testing, such as percutaneous coronary intervention, can further confirm coronary artery blockage as causation. This procedure is an invasive procedure in which a catheter is threaded through the femoral artery, dye is injected, and coronary blockages can be detected through this dye. If the patient is experiencing an acute exacerbation of HF, chest X-rays assist with identifying pulmonary edema or **cardiomegaly**, which means ventricular enlargement to accommodate excess fluid (Figure 12.20). While diagnostic imaging is expansive in the work up of HF, other laboratory values assist with determining disease severity.

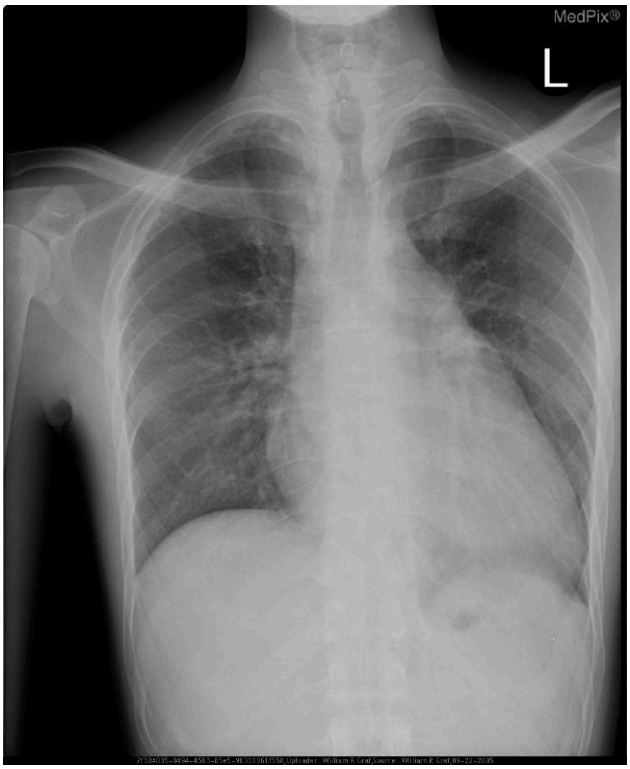

FIGURE 12.20 Due to enlargement, the apex of the heart is taking up the right-side field (the patient's left lung). (credit: "Graves Disease" by Naval Medical Center Portsmouth: William R Graf/National Library of Medicine, Public Domain)

While most diagnostics of HF rely on imaging and patient presentation, there is a sensitive and specific blood test to

identify an acute exacerbation of HF. Serum brain natriuretic peptide (BNP) is a prominent laboratory test utilized in diagnosing HF. The BNP hormone comes from a family of proteins that have a direct effect on blood vessels that affect constriction and dilation (Harvard Health Publishing, 2022). With the increased myocardial stretch in HF, the protein levels rise when the pressure gradients rise in the atria and ventricles. Normal levels of BNP should be less than 100 pg/mL, and may increase slightly due to age, but assessing levels along with the clinical presentations assists the nurse to evaluate the patient's response to treatment.

Additional testing includes electrolyte panels, hemoglobin A1C, liver enzymes, and thyroid-stimulating hormone. Electrolyte panels assist with providing baseline serum potassium and serum and creatinine to consider if there is renal insufficiency. An elevated hemoglobin A1C may indicate metabolic dysfunction; comorbid diabetes that is not well controlled may exacerbate underlying cardiovascular disease. With hepatic congestion from right-sided heart failure, liver function tests may be elevated. Thyroid disorders such as hypothyroidism may trigger an event of HF. Laboratory and serial diagnostics may continue over months or annually to monitor the patient's disease status.

READ THE ELECTRONIC HEALTH RECORD

Sample Laboratory Profile of Patient with HF

Mr. John Smith is admitted with a diagnosis of acute left-sided heart failure. The emergency room nurse has been caring for Mr. Smith as he awaits a bed on the telemetry unit. The nurse reviews his labs over the last 12-16 hours.

Time	0800	1700	2300
BNP	500 pg/mL	750 pg/mL	1500 pg/mL

Time: 2300
ALT: 230 units/L (normal: 7–56 units/L)
AST: 60 units/L (normal: 10–40 units/L)
LDH: 362 units/L (normal: 140–280 units/L)

4. What explains the trend of the BNP rising? What cues would the nurse recognize to support these trends in the BNP?
5. What do the other levels suggest? What does it indicate to the nurse? What assessment findings would the nurse expect to find consistent with these laboratory values?

Nursing Care of the Patient with Heart Failure

Nurses who practice in the cardiovascular specialty are challenged to understand and think critically about the therapies administered to the patient with HF. Most therapies center around pharmacological interventions to control blood pressure, promote diuresis, and reduce preload. Nursing responsibilities include monitoring hemodynamic stability with blood pressure and pulse assessments. It is imperative to monitor the patient's response to the medication, including any side effects, and use clinical judgment to question if the medication should be held, for example, if a pulse is less than 60 bpm. Additionally, education in modifiable risk factors and recognizing signs of cardiac decompensation are integral in the care of a patient with HF.

Recognizing and Analyzing Cues

A general assessment begins by looking at the position of the patient, the breathing pattern, and noting the color of the patient's skin. Note any pallor if it is appropriate for the patient's ethnic background. Note the patient's mentation, if they are alert and oriented, and if they are at baseline for their mental status. Auscultate anterior and posterior lung fields, noting any adventitious sounds, an associated cough (sputum color, consistency, amount), and where the adventitious breath sounds are heard. During a heart assessment, patients with HF may have murmurs, S1/S2 abnormalities, and rate irregularities. During the peripheral vascular assessment, observe for edema in the extremities and for qualities of the peripheral pulses. A gastrointestinal assessment may reveal fluid accumulation in the abdominal unit, noted as ascites, as well as **hepatosplenomegaly** (liver and spleen enlargement) from right-

sided heart failure. Any new changes or deviations from the prior assessment would cue the nurse to consider a new complication of HF or worsening disease.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Oxygenation is the nurse's top priority when planning care for a patient with HF. Often, the patient will report shortness of breath and dyspnea. Putting the patient in high Fowlers will alleviate dyspnea, and ordered supplemental oxygen may be necessary to maintain oxygen saturations greater than 92 percent. For the patient's circulatory support, the administration of ordered beta-blockers, angiotensin converting enzyme (ACE) inhibitors/angiotensin-receptor blockers (ARBs), diuretics, and nitrates requires frequent hemodynamic assessment. The patient's response to diuretic therapy is monitored by daily weights, adhering to strict intake and output. In severe cases of HF, compliance with fluid restrictions may be required. Advise the patient to rest frequently to conserve energy; clustering nursing care around the patient's energy level will assist with reduced fatigue.

Education is critical for the patient being discharged home from an HF hospitalization. The patient should be instructed on modifiable risk factors such as smoking cessation, as nicotine is a vasoconstrictor and applies undue stress on the heart. Reduced or no alcohol consumption is recommended, as alcohol elevates blood pressure. Dietary reduction of high fatty foods and cholesterol will mitigate the development of coronary artery disease. Diets high in sodium increase fluid retention, as water molecules follow sodium molecules into the vascular space and can leak into the interstitial tissue, creating edema. The American Heart Association strongly encourages patients with HF to reduce sodium intake. Encourage the patient to keep sodium intake to less than two grams a day. Weight loss and a gradual increase in physical activity with aerobic exercise promote cardiac conditioning. Primary prevention with immunization for pneumococcal pneumonia, COVID-19, and influenza is recommended to minimize HF recurrences, as infection can strain a failing heart. The nurse must be supportive, nonjudgmental, and patient with the patient.

LINK TO LEARNING

My Healthfinder from the Office of Disease Prevention and Health Promotion has put together a shopping list of lower-sodium foods (https://openstax.org/r/77LowSaltFoods) that can be useful to share with patients who need to limit their sodium intake.

Evaluation of Nursing Care of the Patient with Heart Failure

Creation and evaluation of patient outcomes for HF should align with SMART considerations (specific, measurable, attainable, relevant, and timely). Goal development should center around secondary prevention interventions to prevent exacerbation of HF, and tertiary interventions to stabilize acute HF.

Evaluating Outcomes

A patient who demonstrates adequate oxygenation with a heart failure illness will be able to complete clustered activities of daily living without reporting shortness of breath and maintain oxygen saturations greater than or equal to 92 percent. For circulatory stabilization, several objective measurements may be used to evaluate to ascertain goal achievement. Patients will demonstrate reduced edema (2+ or less) and maintain blood pressure (norms may be patient-individualized) with pharmacological therapies. Other evaluation parameters may consider fluid status, stable weight, or verbalizing understanding of fluid and sodium restriction. Lastly, in consideration of safety, the patient's medication regimen will reconcile with the provider's orders (Table 12.2).

Outcome Area	Goals	Evaluation Criteria
Oxygenation	Patient will complete clustered activities of daily living without shortness of breath. Maintain oxygen saturation ≥ 92%.	• Ability to perform activities without shortness of breath • Oxygen saturation levels ≥ 92%
Circulatory stabilization	Patient will demonstrate reduced edema (2+ or less) and maintain individualized blood pressure norms with pharmacological therapies.	• Edema level ≤ 2+ • Blood pressure within individualized norms
Fluid status	Patient will maintain stable weight and verbalize understanding of fluid and sodium restrictions.	• Stable weight • Verbalization of understanding fluid and sodium restrictions
Medication safety	Patient's medication regimen will reconcile with the provider's orders.	• Medication regimen matches provider's orders

TABLE 12.2 Evaluating Outcomes for a Patient with Heart Failure

A comprehensive, holistic approach is necessary to evaluate the therapeutic response of the patient. HF requires continued maintenance of medication adherence, modifiable risk factor management, and self-monitoring of disease. Acute exacerbations of HF require stabilization of symptoms and, if hospitalized, management of disease to be safely discharged to the community.

Medical Therapies and Related Care

Many pharmacological therapies directed at HF are indicated to reduce symptom burden and prevent disease progression. Pharmacological agents utilized in the treatment of HF include beta-blockers, diuretics, ACE inhibitors/ARBs, and nitrates.

Beta-blockers are utilized to reduce myocardial oxygen demand, vasodilate, and reduce heart rate. Cardio-selective beta-blockers such as metoprolol work exclusively on the beta (1) sites in the heart, whereas carvedilol, a nonselective beta-blocker, works on both beta (1) and beta (2) sites. Patients with a history of asthma or broncho-constrictive disease should have a thorough lung exam, and these medications should be used cautiously, as non-cardio-selective beta-blockers may trigger bronchospasm and may be problematic for the patient. Most beta-blockers are well-tolerated by patients and are administered in long-acting forms or intermediate release. Patients should be educated on compliance with taking the medication and should contact their provider if there is a reason to stop or hold the medication.

Diuretics assist in the facilitation of fluid removal via the renal system. Considered preload reducers, potent diuretics such as furosemide work on the loop of Henle and increase fluid excretion. Nursing assessments include strict intake and output, serial potassium monitoring, and daily weight monitoring. A therapeutic response would include reduction of weight gain and edema, and increased ease of breathing. Electrolyte monitoring of serum potassium and blood tests for blood urea nitrogen and creatinine is necessary with intravenous diuretics, as potassium wasting is increased and there is a risk of acute kidney injury. If diuretics are too potent for the patient, dehydration and hypotension may complicate the patient's response. Also, intravenous push furosemide must be administered slowly to avoid ototoxicity.

Many pharmacological therapies address the changes in preload and afterload in a failing heart. The American College of Cardiology (2016) gives a Class 1 recommendation that patients with reduced ejection fraction should be on daily ACE inhibitors or ARBs (Table 12.3). Angiotensin is converted by the lungs from angiotensinogen originating from the kidneys. Angiotensin is a hormone that is responsive to decreased perfusion to the nephrons. When perfusion to the kidneys is decreased, the angiotensin I hormone converts to angiotensin II and activates renin, which stores extra fluid and reduces excretion. While HF pathophysiology operates with a disequilibrium of fluid balance, ACE inhibitors and ARBs are indicated to combat this effect. A common example of an ACE inhibitor is lisinopril, while valsartan is an ARB.

Nursing assessments include monitoring for hyperkalemia, blood pressure response, and side effects. A new onset of cough is a common complaint with ACE inhibitors. While unpleasant, it does terminate a few months after initiation of therapy or may resolve only after discontinuation of the medication. Common practice is to switch to an ARB or another class of antihypertensive. Nurses must educate the patients on the side effects and self-monitoring of blood pressure at home.

Class	Drug	Dosing
ACE inhibitor	Lisinopril	2.5/5/10/20/40 mg per day
	Benazepril	10/20/40 mg per day
	Enalapril	2.5/5/10/20 mg per day
	Captopril	6.25-12.5 mg PO every 8 hours
Angiotensin-receptor blocker	Losartan	25/50/100 mg per day
	Valsartan	40/80/160/320 mg per day
	Irbesartan	150/300 mg per day
	Olmesartan	10/20/40 mg per day

TABLE 12.3 Common ACE Inhibitors and ARBs

Nitrates, potent coronary vasodilators, are another example of preload reduction. They may be administered as a patch, orally, sublingually, or spray-routed into the mouth. Patients on chronic nitrates should monitor blood pressure closely, as orthostatic hypotension may occur as a complication. Caregivers or family members who apply patches for patients should be directed to wear gloves. Passive absorption of the topical cream onto the administrator's hands may produce hypotensive side effects.

12.4 Hypertension

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations of hypertension
- Describe the diagnostics and laboratory values in the disease of hypertension
- Apply nursing concepts and plan associated nursing care for the patient with hypertension
- Evaluate the efficacy of nursing care for the patient with hypertension
- Describe the medical therapies that apply to the care of hypertension and the Joint National Committee (JNC 8) guidelines for the treatment of hypertension

The Centers for Disease Control (2022) notes that almost half of individuals in the United States are afflicted with hypertension (HTN). According to the American Heart Association (2023), HTN costs the United States between $131 and $198 billion each year. Men (50%), Blacks (56%), non-Hispanic White adults (48%), non-Hispanic Asian adults (46%), and Hispanic (39%) adults are more likely to have HTN (CDC, 2022). Age, gender, and ethnic and

racial disposition are nonmodifiable risk factors. Modifiable risk factors for HTN include diabetes, a diet high in sodium and low in potassium, physical inactivity, obesity, excessive alcohol use, and tobacco use. Uncontrolled blood pressure can result in stroke, heart disease (coronary heart disease, congestive heart disease), arrhythmia, and kidney disease.

Pathophysiology

There are two types of HTN. Though the cause for these types varies, the manifestations and sequelae do not. The two classifications are primary or essential hypertension and secondary hypertension. Often multi-factorial, **primary hypertension** does not have one distinct cause, while **secondary hypertension** is caused by another medical condition, such as thyroid issues or adrenal or kidney disease.

In the early stages of HTN, increased cardiac output creates high blood velocity to counteract the tightened arterioles. Activation of the renin-angiotensin hormonal system is highly correlated with renal endocrine function. When perfusion is decreased in the kidneys, renin is released and converts angiotensin I to angiotensin II (released from the kidneys), which increases blood pressure. Also, physiological influences from the autonomic nervous system (sympathetic nervous system) activation influence arteriolar constriction and dilation. Other factors that contribute to the pathophysiology of HTN include hypercoagulability, in which viscous blood is created from endothelial dysfunction and results in increased pressure. Peripheral resistance is increased from tight endothelial intimal thickening in small arterioles (Gallo et al., 2021). Hemodynamic cutoff parameters with systolic pressures ≥ 140 mm Hg/diastolic ≥ 90 mm Hg are consistently elevated in hypertensive patients (World Health Organization, 2023).

Clinical Manifestations

Blood pressure will periodically rise during moments of stress, anxiety, or physical activity. While there are transient rises in blood pressure during these moments, readings do not remain consistently high. Consistent high blood pressure may not cause any symptoms. Often referred to as the "silent killer," elevated readings may be discovered during routine physical exams. Symptomatic hypertension may cause headaches, nose bleeds, fatigue, nausea, chest pain, and shortness of breath. In severe cases, patients with **hypertensive urgency** may report chest pain, shortness of breath, blurred vision, and headaches (resulting from elevated intracranial pressure), but do not exhibit target organ damage (American Heart Association, 2024). In contrast, patients with **malignant hypertension** will exhibit similar symptoms with target organ damage, such as kidney failure or pulmonary edema (Naranjo et al., 2023).

The American Heart Association (2022) notes blood pressure readings may rise as high as 180/120 mm Hg to be considered a hypertensive urgency or emergency; however, some patients will experience severe symptoms with readings 160/90 mm Hg or greater. It is prudent for nurses to recommend patients proceed to an inpatient facility for treatment and evaluation. Table 12.4 demonstrates the progression of high blood pressure based on systolic readings.

Classification	Criteria
Normal blood pressure	120-129/80 mm Hg
Stage I hypertension	130-139/80-90 mm Hg
Stage II hypertension	140/90 mm Hg or higher
Hypertensive urgency	160/90 mm Hg or higher

TABLE 12.4 Classification of Blood Pressure (Mayo Clinic, 2024)

Diagnostics and Laboratory Values

Assessment begins with a thorough medical history inquiring about genetics, comorbid conditions (elevated lipids, diabetes, obesity), and lifestyle practices. The nurse assessing the blood pressure must take two blood pressure

readings on two different occasions, using a properly sized cuff (Figure 12.21). The patient should be positioned in a comfortable environment and should be instructed to sit with legs uncrossed. They should abstain from eating and smoking a minimum of 30 to 45 minutes prior to testing. If the patient demonstrates anxiety, permit rest first, as being in medical facilities may cause elevated readings. This is also known as "white coat syndrome." Hypertension is diagnosed for patients with high blood pressure that is seen in two separate clinic visits at least two weeks apart, and on both visits.

FIGURE 12.21 Selecting the correct blood pressure cuff size is necessary to get an accurate reading. The pediatric size is often green, adult size is black or blue, and maroon is for patients with large arms. (credit: Amanda Mills/CDC, Public Domain)

Manual blood pressure readings are always the best practice; therefore, if automated noninvasive blood pressure monitoring yields elevated measurements, the nurse should follow up with a manual reading.

Other diagnostic tests include a 12-lead electrocardiogram (EKG). Twelve lead EKGs may demonstrate ischemia, heart failure, or dysrhythmia to explain organic causes of HTN. The provider may order laboratory values such as a basic metabolic panel, lipid profile, fasting blood sugar, and urine test (protein) (Unger et al., 2020). The clinical work up of other chronic comorbidities is considered when there is a new diagnosis of HTN. It is of utmost importance that the blood pressure readings are taken correctly and in a consistent manner. The nurse must also note if the patient is demonstrating any symptoms of elevated blood pressure, which may include headache, chest pain, blurred vision, shortness of breath, fatigue, or dizziness. Patient presentation is paramount to consider the effects of the elevated blood pressure, not the abnormal value in isolation.

CLINICAL SAFETY AND PROCEDURES (QSEN)

Evidence-Based Practice: The Correct Technique for Taking a Blood Pressure

1. The patient must refrain from eating or smoking for 30-45 minutes.

2. Seat the patient in a comfortable environment with both feet on the ground and arm resting on a table or on the lap.
3. Ask patients if there are limb restrictions due to mastectomy or lymph node removal from a history of breast cancer.
4. Ensure the patient's blood pressure is taken with a correctly sized cuff.

Nursing Care of the Patient with Hypertension

In the medical-surgical inpatient setting, nurses will be treating chronic HTN or acute HTN. The accessibility and ease of recognizing trends of hemodynamic changes is to the benefit of the inpatient nurse. Although most of the current nursing literature centers around diagnosing HTN in the outpatient setting, more streamlined practices are in development to accurately diagnose HTN in the acute care setting (Armitage et al., 2019).

Recognizing Cues and Analyzing Cues

The nurse begins the physical assessment by taking a proper BP assessment, noting the position and size of the cuff. The nurse must perform a thorough heart and lung assessment, noting any extra heart sounds, gallops, murmurs, irregularities, or crackles. Note the patient's pulse and assess for edema. Patients with uncontrolled HTN may retain fluid and have an underlying diagnosis of congestive heart failure. Have the patient keep a journal of blood pressure readings to self-monitor medication effects; the nurse should analyze the readings and determine if they are consistently high or low. Note if the patient has any associated symptoms with elevated blood pressure such as headache, chest pain, blurred vision, or shortness of breath.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

First-line interventions with newly diagnosed HTN aim to reduce modifiable risk factors and should be tailored to the individual. If appropriate, encourage the patient to abstain from alcohol and quit smoking. Chronic alcohol use will elevate blood pressure and interfere with pharmacotherapeutics. Nicotine is a vasoconstrictor and contributes to elevated readings. Provide education to the patient on long-term effects from these modifiable risk factors. Patients may have to reduce or eliminate caffeine as needed to avert elevated blood pressure readings.

Educate the patient on physical activity recommendations. The American Heart Association recommends at least 150 minutes of physical activity per week. Sodium reduction in the diet is recommended, as excess sodium leads to fluid retention and will result in elevated readings. Diets high in saturated fats and sugar are linked with endothelial intimal dysfunction. Patients may benefit from interprofessional referral to a registered nutritionist or physical trainer to assist with goal development in aerobic activity.

Lastly, the patient must be made aware of the symptoms of symptomatic hypertensive readings. If the nurse suspects that the patient is having an acute hypertensive event, assess the patient's blood pressure and document symptoms and onset. Therapies will be initiated inpatient per the provider's order (intravenous hydralazine, intravenous beta-blockers), labs to assess for target organ damage, and telemetry to monitor for serial blood pressures and rhythm. Oftentimes, patients trivialize symptoms with elevated blood pressure measurements; nurses can assist patients with safe triage and access to care. When planning goals for patients with HTN, they must align with the patient's preferences and intended clinical responses. Goals may include a demonstration of knowledge of symptoms of hypertensive crisis, adherence to medication therapy, increase in physical activity, alteration in modifiable risk factors, and normalization of blood pressure readings. The nurse must understand goals may have to be adjusted based on the patient's condition.

Evaluation of Nursing Care of the Patient with Hypertension

In most cases with acute presentations of HTN, goal creation will focus on secondary and tertiary prevention of complications. Goals will have to be tailored to the degree of symptom burden and risk factors.

Evaluating Outcomes

With HTN, patient goals center around SMART concepts. The following outcomes are measurable and can be adjusted to reflect short-term or long-term outcomes.

- The patient's blood pressure should be reduced below 120/80 mm Hg with medication adherence.
- The patient will comply with the therapy and efforts to modify lifestyle choices that are risk factors.

- The patient will demonstrate knowledge of sodium discretion and make appropriate menu choices that are low-fat and low-glycemic.
- The patient will participate in a moderate exercise program for 30 minutes (five times a week).
- The patient will maintain a healthy BMI (target < 30%, anything over 30% is obese).

Collectively, patient empowerment through education and adherence to medical therapy will yield the desired responses. Patients may struggle to accept the disease and restrictions; however, patient-centered care with realistic goals will prove effective.

Medical Therapies and Related Care

Recently released guidelines endorsed by the Joint National Committee updated guidelines for the pharmacological therapies for patients with HTN (Cifu & Davis, 2017), which will be referred to as the JNC 8 in this text. For the non-Black population (with or without diabetes), initial therapy should include thiazide diuretics, CCBs, ACE inhibitors, or ARBs. In contrast, the Black population (with or without diabetes) should be started on thiazide diuretics or CCBs. Current guidelines encourage ACE inhibitor/ARB therapy for Black individuals with HTN to reduce the risk of stroke. Upward titration of medications should occur with proper assessment of blood pressure response. If these initial therapies do not achieve a therapeutic response, the addition of CCBs, ACE inhibitors, or ARBs will be considered. Other agents to consider are beta-blockers or aldosterone agents. While nurses are not responsible for the prescribing of the medication, they must consider whether their patients are at high risk of heart-related complications such as HF, heart attack, and stroke. The most recent developments endorse closer outpatient monitoring of blood pressure, adding potassium supplementation, and adhering to lifestyle recommendations. New recent guidelines endorse the implementation of sodium-close cotransporter-2 inhibitors (SGLT-2) for patients with HF and HTN. Nursing responsibilities include monitoring hemodynamic response, monitoring for side effects, and teaching correct techniques for at-home self-monitoring of antihypertensive therapies. Hemodynamic monitoring may be conducted by the nurse, or the patient will be educated on home monitoring. With the integration of sophisticated technology, current software permits telemonitoring and the use of smartwatches or tablets to assist patients with monitoring therapies.

12.5 Myocardial Infarction

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations of myocardial infarction
- Describe the diagnostics and laboratory values of myocardial infarctions
- Apply nursing concepts and plan associated nursing care for the patient with myocardial infarction
- Evaluate the efficacy of nursing care for the patient with myocardial infarction
- Discuss the medical therapies that apply to the care of myocardial infarction

Coronary disease afflicts 7.1 percent of adults aged 45-65, 10.9 percent of adults aged 45 years and older, and 17 percent of adults 65 and older (CDC, 2019). Coronary heart disease (CHD) affects White people the most, followed by Black people, Hispanic people, and Asian and Pacific Islander people. Social determinants of prevalence include a lack of higher education, physical inactivity, smoking, and lack of disease surveillance. Patients with comorbid conditions such as diabetes, chronic kidney disease, chronic obstructive pulmonary disease, cerebrovascular disease, and peripheral artery disease have a 26 percent increased risk for mortality following myocardial infarction (MI) (Baechli et al., 2020).

Pathophysiology

The four major coronary vessels are the right coronary artery, the left main coronary artery, the left circumflex artery, and the left anterior descending artery (LAD) (Figure 12.22). The right coronary artery branches off the aorta, where oxygen-rich blood perfuses the right ventricle and assists with right ventricular contraction. It also perfuses the native sinoatrial node, which is the “pacemaker” of the heart. The left circumflex artery supplies blood to the left atrium, whereas the LAD perfuses the anterior wall. The LAD is not only solely responsible for perfusing the anterior wall of the heart but also perfuses other cardiac landmarks such as the septum and lateral anterior wall. Due to the high demand of the left atrium and left ventricle to perfuse the body, the left main coronary artery assists with perfusion to these chambers. Cardiac cells are sensitive to coronary perfusion, in that cells do not function properly

under periods of blood flow deprivation or, in worse cases, myocyte death (infarction) with prolonged perfusion defects.

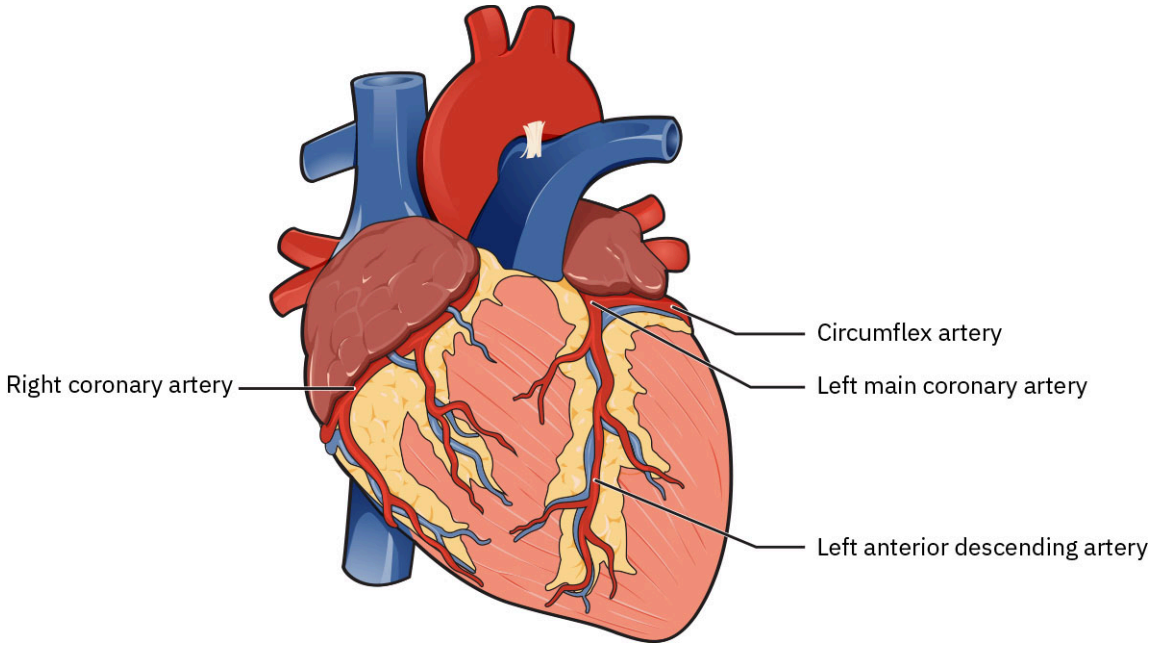

FIGURE 12.22 The coronary arteries supply blood to the heart muscle. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Clinical Manifestations

The clinical presentation of myocardial infarction can be very vague and not every clinical presentation is the same. Typically, patient interviews and clinical diagnostics cue the nurse for a high index of suspicion if a myocardial event has occurred or is occurring.

Age-related changes and lifestyle influences may influence the diameter and plaque occlusions of a diseased coronary artery. Initially, endothelial intimal thickening is compounded by plaque formation, whose composite is from high concentrations of low-density lipoprotein (LDL). Traveling platelets and red blood cells aggregate at the sites of plaque build-up and start to form a clot or a thrombus. Two physiological insults may happen. Under the first condition of physical duress, called **ischemia**, the coronary artery becomes constricted to the point where blood flow is temporarily stopped but resumes with medication or rest. If the same conditions occur, but blood flow to the myocardium is cut off completely, the cells die, called **infarction**. Symptom presentation and lethality may depend on the degree of infarction and which coronary artery is involved.

CLINICAL SAFETY AND PROCEDURES (QSEN)

Evidence-Based Practice: Intervention Time for Myocardial Infarction

1. Note the onset of chest pain for a patient with a high suspicion of myocardial infarction.
2. Patients who have no relief of chest pain after three doses of nitrates that are dosed at 5-minute intervals apart have a high risk of acute coronary syndrome.
3. Evidence recommends activating the emergency medical system to assist with a 90-minute window from the onset of chest pain to angioplasty intervention to maximize perfusion outcomes from a myocardial infarction.
4. Administer 325 mg aspirin for platelet aggregation.

Diagnostics and Laboratory Values

Chest pain or discomfort that occurs when blood flow to the heart is reduced is called **angina**. Stable angina is typically reversed with rest or pharmacological intervention, whereas unstable angina requires both rest and pharmacological support and can last several minutes. Classic symptoms include chest pain; pain radiating to the jaw, arms, neck, back, or stomach; shortness of breath; lightheadedness; and excessive sweating, also known as

diaphoresis. A diagnostic workup entails the measurement of serum troponins and creatine kinase MB to rule out myocardial infarction. Serum **troponin** is a protein secreted when cardiac tissue is damaged, typically six to eight hours following a myocardial infarction (British Heart Foundation, 2024). The enzyme **creatine kinase MB (CK-MB)** is secreted in the presence of damaged cardiac tissue (Medline Plus, 2023). Its levels will peak in a few hours and decrease in two days. Most emergency departments will measure troponins every six to eight hours for three levels to fully rule out myocardial infarction.

Other diagnostic tools besides blood work are necessary to complete the workup. An EKG may demonstrate abnormalities with the T waves, in which the T waves will be flipped or the ST segment will be depressed (Figure 12.23). If a patient is asymptomatic, an echocardiogram may demonstrate ventricular wall motion abnormalities. Invasive procedures such as angiography may reveal coronary blockages, which will be further discussed.

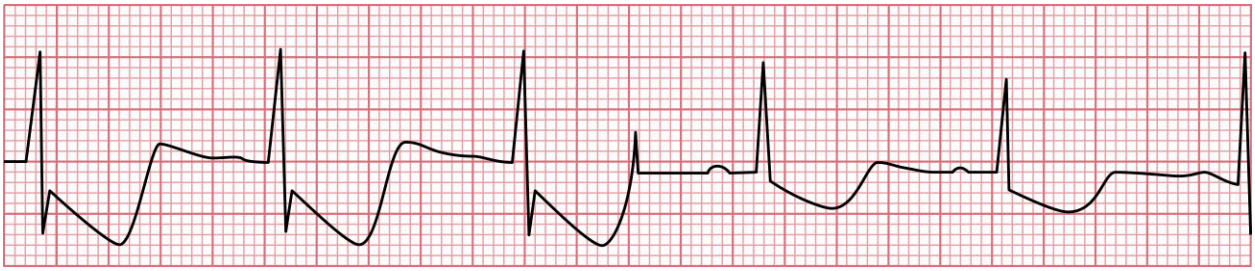

FIGURE 12.23 Depression of the ST segment will be seen in angina. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

In the acute phase of an anginal episode, nursing care focuses on maximizing the re-initiation of oxygenation to the blocked coronary vessel. Patients will have their chest pain managed, receive supplemental oxygen, and maintain bed rest. The nurse will monitor hemodynamics by applying telemetry monitoring.

An umbrella term, **acute coronary syndrome (ACS)** includes the following: non-ST-elevated myocardial infarction (NSTEMI), ST-elevated myocardial infarction (STEMI), and unstable angina (Figure 12.24). With an NSTEMI, there are no abnormal changes in the EKG; however, there would be a rise in the troponins and CK-MB levels. In contrast, with a STEMI, there are abnormal EKG changes with elevation of the ST segment in a 12-lead EKG with an upward trend in the troponins and CK-MB. Lastly, unstable angina presents with symptomatic chest pain that radiates to the jaw or down the left side with associated nausea, diaphoresis, dizziness, and fatigue that does not resolve with rest or with three doses of nitroglycerin administered five minutes apart. STEMIs require prompt, emergent intervention with angiography, as damage is more likely to extend deeper into the cardiac muscle.

Nursing Care of the Patient with Myocardial Infarction

The care of the patient experiencing an MI differs whether it is in the acute phase or post-recovery phase. The best outcomes occur when nurses recognize “muscle is time,” and prompt identification is the key. Rapid treatment will vary in the acute interventional phase compared to the post-recovery phase of myocardial injury.

Recognizing and Analyzing Cues

The very first assessment the nurse must initiate is a set of vital signs, noting any deviation from normal parameters. Findings will vary: a patient experiencing MI may be hypotensive or hypertensive or will have bradycardia or tachycardia. A low pulse oxygenation of < 92 percent will indicate the patient has hypoxia. The nurse will inspect the patient’s skin, noting any evidence of cyanosis or evidence of dyspnea. The patient’s capillary refill and a distal pulse

assessment of the radials and dorsalis pedis are necessary to monitor distal perfusion and to obtain a baseline if the patient proceeds to angiography. Peripheral pulse assessments are required in the post-care of a patient undergoing angiography, and baseline assessment is required. A subjective assessment inquiring about chronic health conditions, lifestyle practices, and medication reconciliation is required.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Associated acute nursing care for the patient with MI includes the concepts of oxygenation, perfusion, and pain management. With oxygenation, the nurse must maintain pulse oximetry over 92 percent and apply telemetry with frequent hemodynamic monitoring to assess perfusion difficulties. The nurse promotes a quiet environment to decrease elevations in blood pressure and decrease oxygen demand. If the patient undergoes angiography, the patient must lie flat for a minimum of four to six hours post-procedure to reduce bleeding risk at the femoral artery puncture site. If the patient is experiencing any further chest pain, note the onset of chest pain, as ideal outcomes improve if the time from symptom onset to angiography is reduced. If the patient requires a coronary artery bypass graft (CABG) (Figure 12.25), a higher level of care in the intensive care unit level is required, as the patient is likely to be ventilated, have chest tubes, and require surgical incisional management.

Once stabilization of MI has been achieved, education is a core component of disease management. Education is directed at dietary adjustments (low saturated fat, low cholesterol, monitor processed foods), smoking cessation, and limiting/omitting alcohol. Following an MI event, the patient will participate in cardiac rehabilitation with a program to increase aerobic activity. Nurses must educate patients about sexual intimacy; often cardiologists will recommend safe resumption of intimacy if the patient can ascend a flight of stairs without chest pain, fatigue, or shortness of breath. Education should also include information about stress reduction strategies such as meditation, guided imagery, or yoga. Compliance with medications and follow-up with provider care are also necessary.

UNFOLDING CASE STUDY

COVID Complications: Part 2

Refer to COVID Complications: Part 1 for the first part of this patient's medical history. He has now been transferred to the ICU.

Nursing Notes	**2/20/2024, 12:30, Triage Assessment** Patient presents to ICU. Increased agitation, increased VS, increased effort to breathe. Dry non-productive cough. Lung sounds with diminished bases and mid-lung field, with increasing crackles from baseline. Tachycardia, repeat ABG demonstrating respiratory acidosis with lower pH, decreased PO_2, and increased PCO_2 from baseline. Weak, bodily fidgeting has decreased. Not following all appropriate commands. **Intervention** Obtain coagulation profile Initiate isolation precautions for COVID Placed on ventilator per provider's settings: positive end-expiratory pressure support of 5 cm/H_2O IV rate of 75 ml/hr Continuous cardiac monitor and pulse oximetry Albuterol nebulizer ×1 via ET tube, administered by respiratory therapy Sputum culture obtained via ET tube ABG stat Acetaminophen 650 mg suppository PR for temperature > 100.7 Sedation, diprivan IV drip 1 mg/kg Labetalol 5 mg IV initial IV push dose for a BP > 160/90. May repeat 5 mg dose IV push ×2 administered every 10 minutes until the systolic blood pressure is within the desired range Notify provider if ineffective according to parameters provided Initiate hyperglycemic protocol as indicated Heparin drip IV 5,000 U bolus and heparin drip continuous at 1,000 U/hr Troponin Cardiac enzymes ×3 Cefazolin 1.5 mg IV every 6 hr Continuous reassessments VS: BP, HR, RR, temperature, O_2 saturation Monitor blood sugars every 4 hr **02/20/24, 13:00, Assessment** Physical Examination: HEENT: pupils equal and reactive to light, mucus membranes dry, no thyroid enlargement. Lymphatic: lymphatic nodes were not swollen or enlarged. Respiratory: increased agitation, increased VS, increasing effort to breathe. Lung sounds with diminished bases and mid-lung field, with increasing crackles from baseline. Cardiovascular: tachycardia, repeat ABG demonstrating respiratory acidosis with lower pH, decreased PO_2, and increased PCO_2 from baseline. Abdomen: soft, denies pain by shaking head no, not distended, bowel sounds present all four quadrants. Musculoskeletal: weak, bodily fidgeting has decreased. Not following all commands. Skin: pale, warm, and moist; patient sedated. **02/21/2024, 00:00** Patient sedated, remains on ventilator. Skin cool and moist. Hypotensive, initiate IV norepinephrine drip. ET tube suctioned with yellow secretions, remains febrile. **02/21/24, 04:00** Physical Examination: HEENT: pupils equal and reactive to light. Respiratory: increased agitation, remain on ventilator with positive end expiratory pressure lung sounds with diminished bases and mid-lung field, with increasing crackles from baseline Cardiovascular: tachycardia, repeat ABG demonstrating respiratory acidosis with lower pH,

	decreased PO_2, and increased PCO_2 from baseline. Abdomen: soft, denies pain by shaking head no, not distended, quiet bowel sounds present all four quadrants. Musculoskeletal: weak, bodily fidgeting has decreased. Not following all commands to move extremities. Skin: warm and moist. Renal: hourly urine output 5 ml past 3 hours **Intervention** Hemodynamic monitoring initiated with frequent hemodynamic monitoring to assess for perfusion difficulties. Quiet environment to decrease elevations in blood pressure and decrease oxygen demand. Continued monitoring of oxygenation, perfusion, and pain management, including hemodynamic values, VS. ABG to assure adequate tissue perfusion and oxygenation. Antiplatelet and/or anticoagulation therapy according to provider's orders (based on lab reports). Increase IV rate to 125 ml/hr (fluid resuscitation).
Flow Chart	**02/20/24, 12:30 Assessment** Blood pressure: 100/98 Heart rate: 110 Respiratory rate: 16 per min rate per ventilator Temperature: 102.3 Oxygen saturation: 89 % on 4 Lpm Patient intubated on ventilator. Ventilator setting ordered per provider. **02/21/2024, 00:00** Vital signs: BP: 100/60 HR: 140 RR: 16 per ventilator-positive end expiratory pressure support of +10 cm/H2 (PEEP) Temp: 102.5

Lab Results	**02/20/24, 13:00** ABG pH: 7.30 PCO_2: 62 mm Hg PO_2: 70 mm Hg HCO_3: 30 mEq/L BS: 100 mg/dL Blood culture: positive for *Pseudomonas aeruginosa* Sputum culture: positive for *Staphylococcus aureus* Troponin elevated: 40 ng/l CK-MB-Cardiac enzymes elevated **02/20/24, 18:00** CBC with differential, pending WBC: 14.5 cells/mm^3 Hgb: 15 g/dl Hct: 40% INR: 1.0 BUN: 19 mg/dl Creatinine: 1.09 mg/dl Lactic acid: 3 mmol/L Na: 140 mEq/L K+: 3.8 mEq/L Cl: 100 mEq/L Pulse oximetry: 92% ABG: pH: 7.31 PCO_2: 55 mm/Hg PO_2: 60 mm/Hg HCO_3: 30mEq/L **02/21/24, 03:00** ABG: pH: 7.32 PCO_2: 50 mm/Hg PO_2: 75 mm/Hg HCO_3: 22 mEq/L BS: 180 mg/dL Lactic acid: 4.0 mmol/L

Diagnostic Tests/ Imaging Results	**02/20/24, 16:00** EKG: acute anterior lateral myocardial infarction CXR: profuse infiltrates and opacities Echocardiogram: left ventricular dysfunction (decreased wall motion and contractility) Ejection fraction: 40% Temperature: 102.5 **02/21/24, 04:00** Echocardiogram: diffuse LV hypokinesis. Other findings included isolated right ventricular dysfunction. Ejection fraction: 40% CXR: bilateral peripheral and basal; multifocal air space and consolidation of increasing opacities (ground-glass) opacity
Provider's Orders	**02/20/24, 16:00** Initiate isolation precautions for COVID On ventilator per provider's settings IV started left antecubital, #20 gauge of Ringers Lactate rate of 125 ml/hr Continuous cardiac monitor and pulse oximetry Albuterol nebulizer ×1 via ET tube, administer by respiratory therapy Coagulation profile Coagulation profile, then begin repeat heparin 5,000 U IV bolus followed by 1,000 U/hr Troponin Cardiac enzymes ×3 Cefotaxime 1 mg IV every 12 hours Discontinue cefazolin 1.5 mg IV Sedation, diprivan IV drip 1 mg/kg Labetalol 5 mg IV initial IV push dose for a B/P > 160/90. May repeat 5 mg dose IV push ×2 administered every 10 minutes until the systolic blood pressure is within the desired range. Notify provider if ineffective according to parameters provided Initiate hyperglycemic protocol as indicated Continuous monitoring VS: BP, HR, RR, temperature, O_2 saturation **02/21/24, 04:00** Insertion of hemodynamic monitoring. Following readings every 4 hours: Cardiac output Pulmonary wedge pressures Pulmonary arterial pressure Discontinue cefotaxime 1 mg IV every 12 hours Vancomycin 500 mg IV every 6 hours over a period of 60 minutes Vasopressin IV: 0.6-2.4 units/hr (0.6-2.4 mL/hr): consult critical care provider for dosing

1. At this time, the nurse would prioritize which cue as the most likely to be the most critical?

CUE	Acute MI	Possible sepsis	Bacterial pneumonia
Respiratory failure			
Decreased cardiac contractility and dysfunction			
Lactic acid increased			

2. After the nurse prioritizes the patient's clinical problems and needs, identify the correct interventions with the correct rationale from the choices provided.

Intervention	Rationale
Administer vasopressors IV	Hypotension Decreased cardiac contractility
Administer antiplatelets/ anticoagulants	Patient is hypotensive
Increase PEEP on ventilator	Bacterial pneumonia
Administer IV diuretics	Prevents formation of vascular clots (thrombus/embolus)
Hemodynamic monitoring	Monitor effectiveness of therapeutics for pulmonary and heart function

Evaluation of Nursing Care of the Patient with Myocardial Infarction

Patient recovery differs depending on the degree of damage from MI and the interventional treatment. Resumption of activities, returning to work, and restoration of stamina varies from person to person. The American Heart Association (2023) notes individuals will require several months to return to pre-disease levels with physical activity. All goals should be tailored to the patient's physiological abilities.

In the immediate, acute, and tertiary phase of treatment of MI, the nurse must implement pharmacological therapies and prepare the patient for medical or surgical intervention for revascularization. Overall goals include optimizing oxygenation, relieving chest pain, stabilizing dysrhythmias, and preserving myocardial tissue. Once the patient is stabilized, the goals will be directed more toward discharge and cardiac rehabilitation:

- demonstrating adequate oxygenation by maintaining SPO_2 > 92%
- hemodynamic stability with normal parameters for pulse and blood pressure
- resolution of chest pain
- employing rest periods with activities of daily living to conserve oxygen demands
- demonstrating understanding of adherence to medication therapy

Evaluating Outcomes

The nurse must reinforce the importance of staying on a full dose of aspirin and/or antiplatelet therapy as prescribed. Patients recovering from MIs must continue with beta-blockers to reduce the risk of reinfarction. Having the patient verbalize understanding and teach back are effective methods to evaluate understanding. The nurse will monitor the patient's willingness to make lifestyle modifications through smoking cessation and reduction of alcohol intake.

Survival from MI has increased greatly over the years with the advancement of pharmacological and interventional methods. Acceptance of this diagnosis will be life-changing for the patient and family members. The nurse should approach the care of the family unit with a nonjudgmental approach. Interprofessional referral for social services, nutrition, and case management will be considered in the planning of nursing care.

Medical Therapies and Related Care

Medical and surgical interventions include angiography and coronary artery bypass graft. In **angiography**, a catheter is threaded into the femoral artery and fluoroscopy dye is injected into the patient's coronary arteries to assess the presence of coronary blockages. If deemed safe by the provider, a stent, which resembles a coil, will be deployed following an opening of the blockage with ballooning equipment. Angiography is preferred, as the patient will be

under monitored anesthesia care and it is the least invasive. Major risks associated with the procedure include dislodging any clots proximal to the blockage elsewhere, dysrhythmia, or bleeding (Malik & Tivakaran, 2023).

If there are multiple blockages, cardiothoracic surgeons will perform surgical revascularization through **coronary artery bypass graft (CABG)**, a more aggressive form of restoring perfusion, as the patient will require general anesthesia and a higher level of care (Figure 12.25). A CABG is a surgical procedure that relocates vasculature from other vessels in the body, such as the saphenous vein in the leg, into the cardiac vasculature to restore perfusion to the heart muscle. These bypasses may be single, double, triple, or quadruple, depending upon how widespread the blockages are that need to be bypassed.

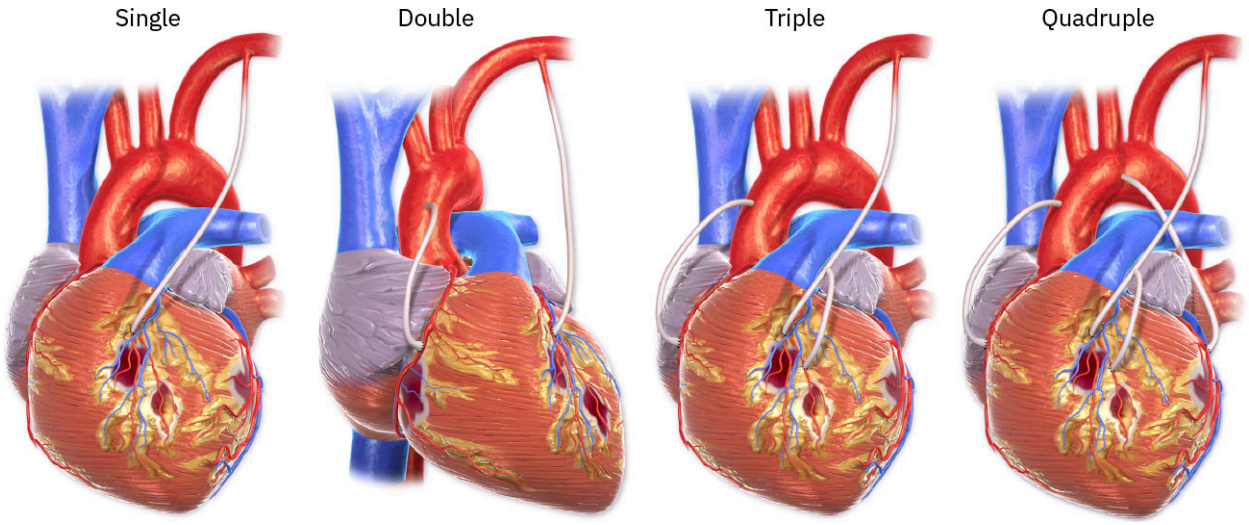

FIGURE 12.25 A coronary artery bypass graft is a surgical procedure that relocates vasculature from other vessels in the body to restore perfusion to the heart muscle. (credit: modification of "Blausen 0152 CABG All" by BruceBlaus/Wikimedia Commons, CC BY 3.0)

Acute pharmacological therapies may include antiplatelets/anticoagulants, nitrates, and beta-blockers. The most common antiplatelet therapy is aspirin 325 mg. Another antiplatelet, clopidogrel 75 mg, reduces the aggregation of a thrombus. Nursing interventions include monitoring for gastrointestinal upset, excessive bruising, and blood in the urine or stool. Anticoagulants, such as heparin, may be administered intravenously as a bolus and continuous drip. Titration of anticoagulants is weight-based and assists with thrombus reduction. The nurse is responsible for monitoring for bleeding and monitoring serum/PTT/anti-factor Xa heparin (institution specific).

Nitrates cause coronary vasodilation which helps to maximize coronary perfusion and reduce ischemia. These medications can be administered via a spray into the mouth, wearable patch paste, or sublingual pills. Nursing assessments include monitoring for hypotension, headache, and response of chest pain resolution. The nurse must use gloves when administering nitro paste to avoid undue side effects.

Beta-blockers are critical to reducing infarct involvement by reducing oxygen demand and lowering heart rate, blood pressure, and contractility, and ideally, improving myocardial oxygenation. The nurse must monitor hemodynamics closely and withhold in cases of symptomatic bradycardia (less than 50 bpm or at the provider's discretion) or low blood pressure (less than 90/50 mm Hg or at the provider's discretion).

Chronic medication therapies include antiplatelets, beta-blockers, and statins. Anti-hyperlipidemic agents are indicated to reduce endothelial inflammation and reduce plaque formation. The nurse must educate a patient taking statins about the importance of avoiding grapefruit juice due to food-drug interaction. The patient must be monitored for hepatotoxicity and educated that myalgias are a common side effect. A month following an MI, an echocardiogram will be completed to assess the left ventricular ejection fraction (EF). If the patient has a depressed EF (less than 40%), ACE inhibitors/ARBs will be initiated to reduce the risk of congestive heart failure.

Lastly, morphine, oxygen, nitrates, and aspirin were previously a therapy for ACS but are no longer practiced. Morphine is not endorsed by the American Heart Association and American College of Cardiology. Oxygen therapy and aspirin are recommended for both NSTEMI and STEMI, but nitrates are only effective for NSTEMI.

12.6 Vascular Disorders

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology and risk factors for vascular disease
- Identify the common laboratory and diagnostic tests for vascular disease
- Apply nursing concepts and plan associated nursing care for the patient with a vascular disease
- Evaluate the efficacy of nursing care for the patient with a vascular disease
- Discuss the medical therapies that apply to the care of vascular disease

The two most commonly occurring forms of vascular disease are carotid artery disease and abdominal aortic aneurysm (AAA). Also referred to as carotid artery stenosis, **carotid artery disease** is a condition that occurs when the carotid arteries, which supply blood to the brain, become narrowed or blocked by the presence of plaque. An **abdominal aortic aneurysm (AAA)** develops when plaque clogs the aorta in the abdomen, causing it to balloon out in an attempt to keep blood flowing through it. Currently, 3 percent of Americans are diagnosed with carotid artery disease (Dossahboy & Ayra, 2021), and 4 to 8 percent of Americans have AAA (Chung, 2021). Individuals with carotid artery stenosis are at high risk for stroke.

When carotid artery disease is identified, it is presumed that vascular disease is also present in the aortic and renal arteries, leading to the risk of AAA and renal disease. Untreated carotid artery disease with significant occlusion can lead to a cerebral vascular accident. A lifestyle of active nicotine use, a diet high in saturated fats, and physical inactivity all add risk to vascular disease. While the majority of AAAs remain stable, AAA dissection, in which the vessel wall tears and hemorrhages blood, occurs annually in approximately 5 to 30 cases per 1 million people (Mancini, 2022).

Pathophysiology

It is important to understand the fundamental terminology and pathophysiology associated with vascular disease. A widespread hardening of the arteries is called **arteriosclerosis,** and **atherosclerosis** is a form of arteriosclerosis in which there is narrowing and reduced blood flow through the arterial wall due to plaque formations (Mayo Clinic, 2022).

An **aneurysm** is an enlargement of an artery, due to a weakened wall from high-velocity flows of blood. An AAA will occur with an endothelial stretching of the aorta due to a stiff and sclerotic arterial narrowing. Eventually, the vessel wall out-pouches and the continued pressures from the high-pressure left ventricle will compromise the vessel wall, and it dissects with blood leaking or, in lethal cases, fully tears through the intima (Figure 12.26).

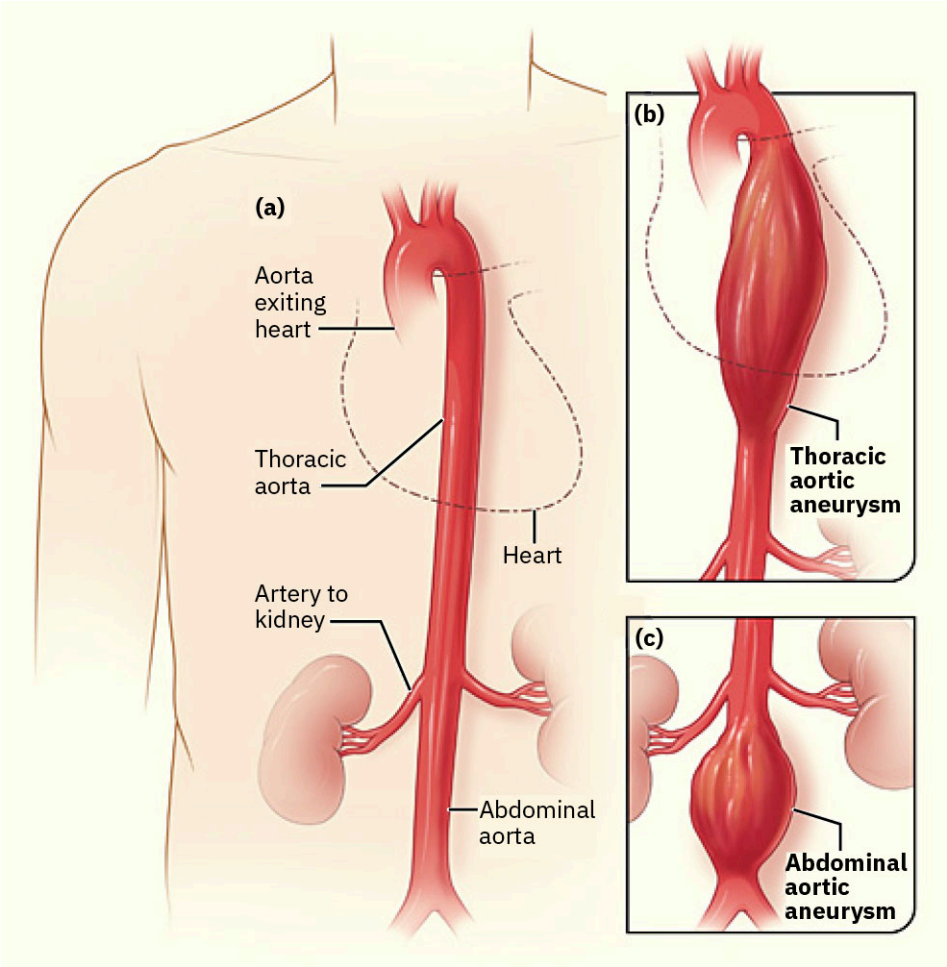

FIGURE 12.26 An AAA will occur with an endothelial stretching of the aorta due to a stiff and sclerotic arterial narrowing. (credit: modification of "Aortic aneurysms. " by NIH: National Heart, Lung and Blood Institute, Public Domain)

Clinical Manifestations

Vascular disease may not be easily identifiable, as some patients may be asymptomatic. Patients with small aneurysms may not even know they have one. Larger aneurysms will cause diaphoresis, dizziness, fainting, tachycardia, nausea and vomiting, shortness of breath, and severe, sudden abdominal pain. A ruptured AAA will manifest as a pulsation in the stomach with pain. In severe cases when it tears, the patient will experience intra-abdominal bleeding. It is important that the nurse asks about the onset of new symptoms and when they began.

Carotid artery disease may or may not cause symptoms depending on the severity of the blockage, or if it is one vessel or both. The patient may report visual changes, experience confusion, memory impairment, "brain fog," or experience numbness or weakness on the side with severe disease (Qaja et al., 2024). With more severe blockages, syncope and passing out may ensue.

Diagnostics and Laboratory Values

The first step in diagnosing carotid artery disease is an ultrasound of the great neck vessels to assess for blood flow velocity abnormalities. Carotid artery blockage greater than 50 percent will likely require pharmacological or surgical intervention. An abdominal or pelvic ultrasound or abdominal computed tomography (CT) is typically sensitive to detect AAA. Diagnostic angiography may be utilized in dual workup of coronary artery disease and AAA. While laboratory values do not directly detect the presence of vascular disease, their abnormal values may suggest its presence. Elevated calcium levels and high lipid levels will lead to diagnostic suspicion of calcium deposits and plaque formation in the arterial intima. An elevated hemoglobin A1C will suggest a background diagnosis of diabetes mellitus, which further increases the risk of vascular disease.

Nursing Care of the Patient with Vascular Disease

While clinical judgment and interventions have similarities of pertinent cardiovascular assessments, brief focused assessments centralize around the diseased vessel. Perfusion alterations may change slowly over time if the diseased vessel has persisted but will normalize if an interventional approach has been taken.

Recognizing and Analyzing Cues

The nurse will begin by performing a focused heart and lung assessment. While assessing the carotid pulse, do not occlude the diseased artery, as this will advance to a syncopal episode. Utilizing the bell of a stethoscope, gently press against the carotid arteries to listen for a **bruit**, which is a "swooshing" sound. Note the presence of the bruit and if it is soft or harsh. For AAA, assess for a non-tender pulsatile mass. Avoid pressing down firmly as this can advance a rupture. A bruit can be heard over the epigastric region as well.

A set of vital signs will identify any episodes of uncontrolled high blood pressure, as this may make a ruptured aneurysm worse. If the AAA ruptures, the patient will manifest with hypotension and tachycardia. The patient must maintain bed rest, and the nurse must call for help by alerting the rapid response team if the patient is hemodynamically unstable. It is likely the patient will be sent to the operating room for intervention. Once the AAA has been repaired, a peripheral vascular assessment will change after a revascularization; if perfusion is restored after correction of a tight vessel or a compromised artery in AAA, it is expected pulses will improve. The nurse must note the quality and character of distal pulses. Blockages from carotid artery stenosis may affect blood flow to the affected limb. Radial pulses and pulses in the feet need to be monitored for post-procedure evaluation so that the blood is not compromised in the limbs.

For safety, patients with occlusions in the carotid artery should change position slowly to avoid dizziness, dangle feet before standing up, or maintain bed rest if unable to safely ambulate. The patient will receive a statin, antiplatelets, antihypertensives, and anti-diabetic agents as necessary. Reinforce lifestyle modification with smoking cessation and healthy eating.

Evaluation of Nursing Care of the Patient with Vascular Disease

Disease stability and improvement in circulation are the main outcomes when evaluating the efficacy of nursing care. The following goals should be incorporated:

- Circulation goals for patients with stable disease are to maintain hemodynamic stability with blood pressures less than 120/90 mm Hg.
- In cases of AAA dissection or carotid artery occlusion, the patient will receive appropriate revascularization therapies.
- The patient's pulses will remain unchanged or improve following revascularization therapies.
- For skin integrity, if the patient is to have a CEA, the incision will remain open to air and will be free of redness, edema, and discharge. Endovascular repair access sites may require the patient to keep the limb straight or remain flat dependent on the access site.

Evaluating Outcomes

Following stabilization, secondary prevention strategies are created to avert further vasculopathy events. The Joint Task Force from the European Atherosclerosis Society and European Society of Vascular Medicine (2023) recommend the patient's low-density lipoprotein target levels less than 70 mg/dL, controlled diabetes with an A1C less than 7 percent, and blood pressure will remain within normal parameters. Patients with vascular disease are likely to have knowledge gaps. Teaching about lifestyle modifications may center around the patient's understanding of the effects of nicotine on vascular health and making healthy nutrition choices.

Vascular disease is a very preventable disease; however, the nurse's role in the care of the patient with these illnesses is influenced by secondary and tertiary preventive strategies. The medical emergent implications with AAA and the progressive features of carotid artery disease require astute physical assessment, knowledge of the vascular system, and the wellness requirements to delay disease. Disease management can be successful with nursing support and informed education.

LINK TO LEARNING

This article discusses the relationship between cigarette smoking and carotid artery disease (https://openstax.org/r/77CigsHeartDis) in Hispanic, Black, and White patients.

Medical Therapies and Related Care

The degree of intervention for AAA will depend on the measurement of the endovascular aneurysm size. The Society for Vascular Surgery recommends annual monitoring for AAAs measuring 4 to 4.9 cm in diameter. For AAAs measuring larger than 5.5 cm, elective (planned) endovascular surgery is indicated; in severe cases with rupture, an open approach is necessary (Chiakof et al., 2018) (Figure 12.27). Similar to the 90-minute door-to-angioplasty time (or "door-to-balloon" time) for coronary reperfusion, the Society for Vascular Surgery recommends the same timeframe for vascular repair of a ruptured AAA (Chiakof, 2018).

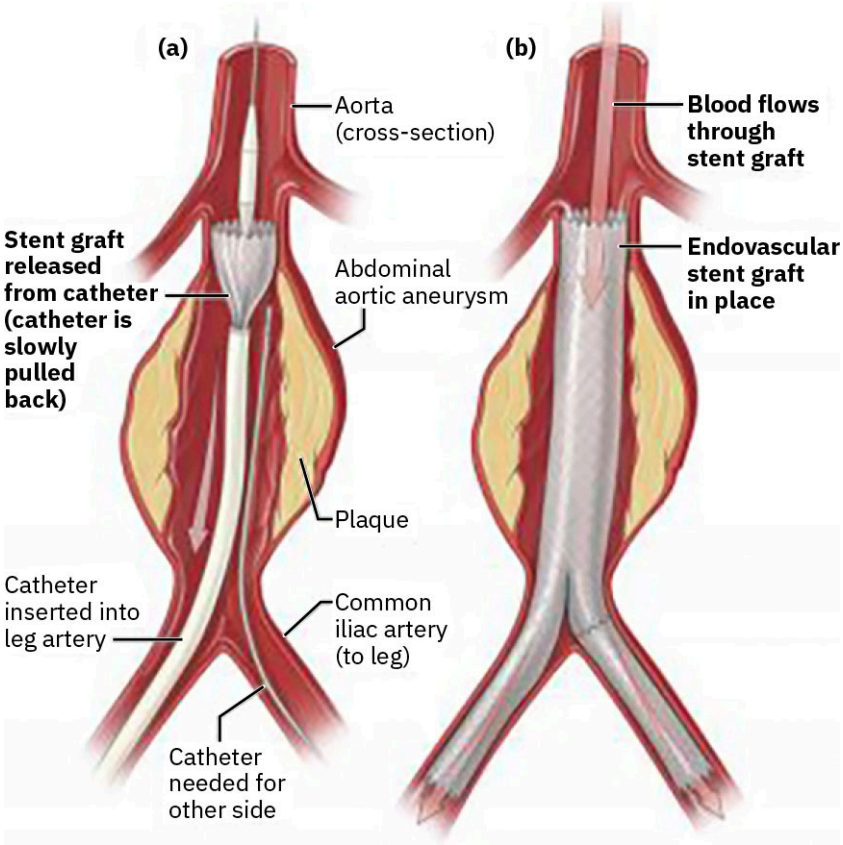

FIGURE 12.27 To perform an endovascular repair, (a) a stent is placed using a guidewire inserted through the femoral artery. (b) It is then grafted in place. The procedure is minimally invasive, and the stent provides stability in avoiding further stretching the abdominal aorta. (credit: modification of "Endovascular repair" by NIH: National Heart, Lung and Blood Institute/Public Domain)

Endovascular intervention is similar in procedure to angiography. A guidewire is inserted into the femoral artery and an expandable stent graft is threaded through the guidewire. The stent permits blood flow and creates stability in the arterial wall, avoiding continued strain on the outpouching (Schanzer, n.d.).

Carotid artery stenosis with less than 50 percent blockage requires medical monitoring. Revascularization with a surgical carotid endarterectomy (CEA) (Figure 12.28) is indicated for symptomatic blockages of 50 to 99 percent and asymptomatic blockages of 70 to 99 percent.

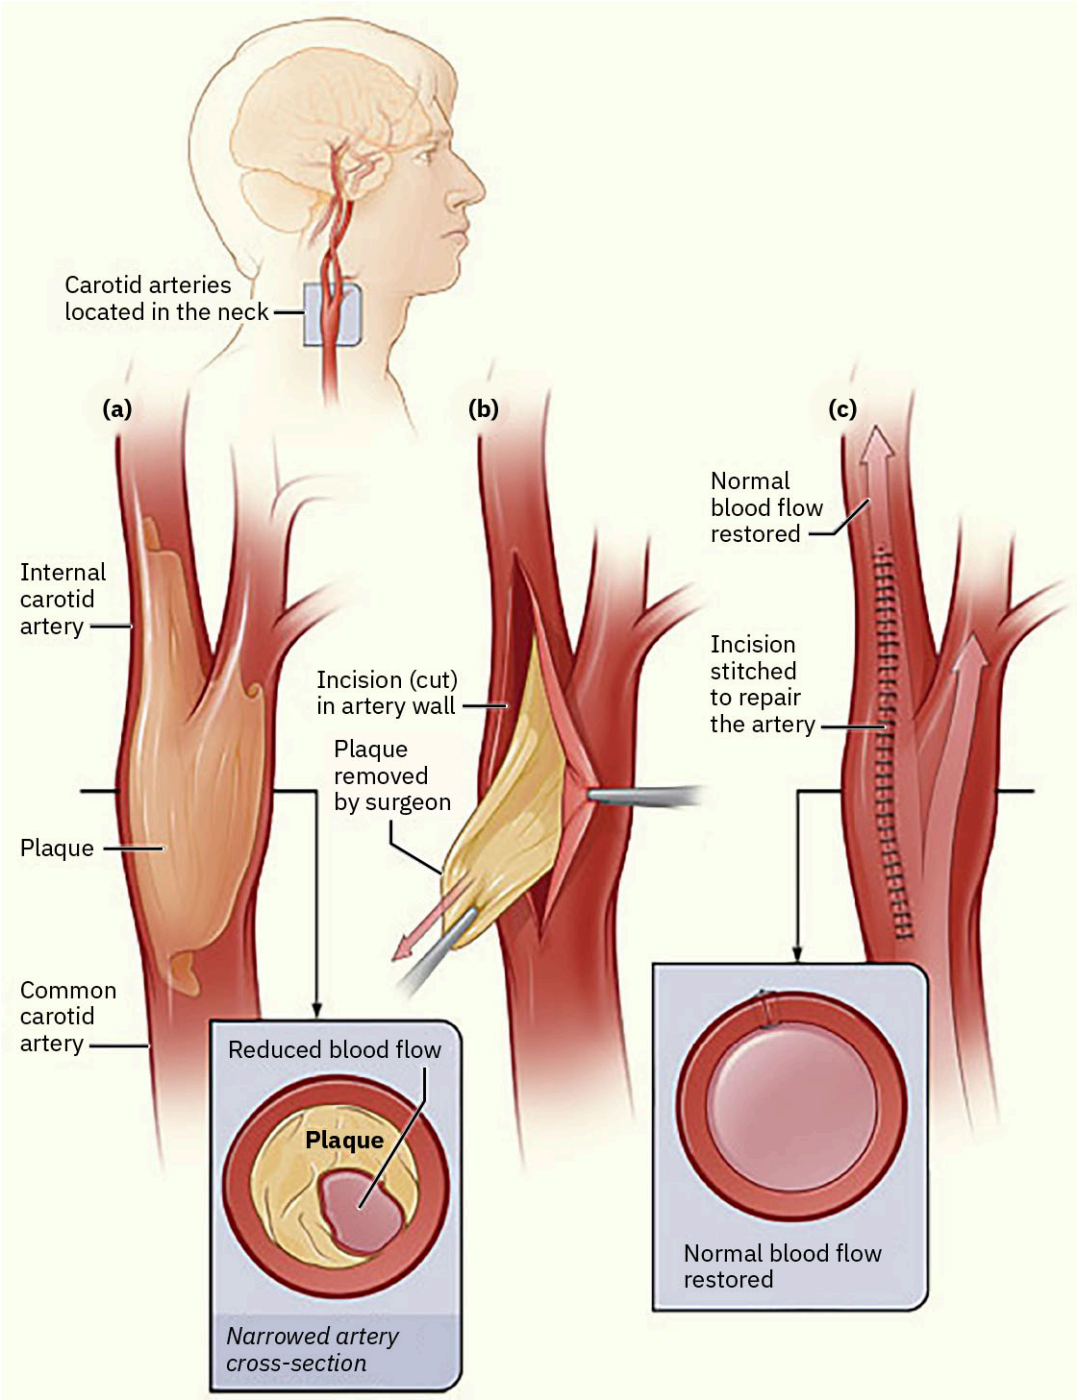

FIGURE 12.28 (a) A carotid endarterectomy is indicated for plaque blockages of 50 to 99 percent. (b) A vascular surgeon makes an open incision, removes excess plaque, and (c) stitches the vessel to close the surgical incision with a mesh closing. (credit: modification of "Cad endarterectomy" by National Heart Lung and Blood Institute (NIH)/Wikimedia Commons, Public Domain)

Pharmacological therapies for both carotid artery disease and AAA are similar in that patients will receive lipid-lowering therapies with statins (e.g. atorvastatin), antihypertensive therapy, and antiplatelet therapy (i.e., chronic aspirin therapy) as necessary. Diabetes control, when applicable, is also important. Lifestyle modifications such as smoking cessation, a low fat/low cholesterol diet, limiting or omitting alcohol, and exercise are also recommended to reduce the risk of further plaque formation.

12.7 Peripheral Vascular Disease

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations of peripheral vascular disease
- Identify the common laboratory and diagnostic tests for peripheral vascular disorders
- Describe the clinical manifestations and nursing care for venous insufficiency
- Describe the clinical manifestation and nursing care for arterial insufficiency
- Evaluate the efficacy of nursing care for the patient with peripheral vascular disease
- Discuss the medical therapies that apply to the care of peripheral vascular disease

Peripheral vasculature is the vasculature extending beyond the heart. It includes the arteries, arterioles, capillaries, venules, and veins (Figure 12.29). Understanding this anatomy and physiology is important to the understanding of peripheral vascular disease.

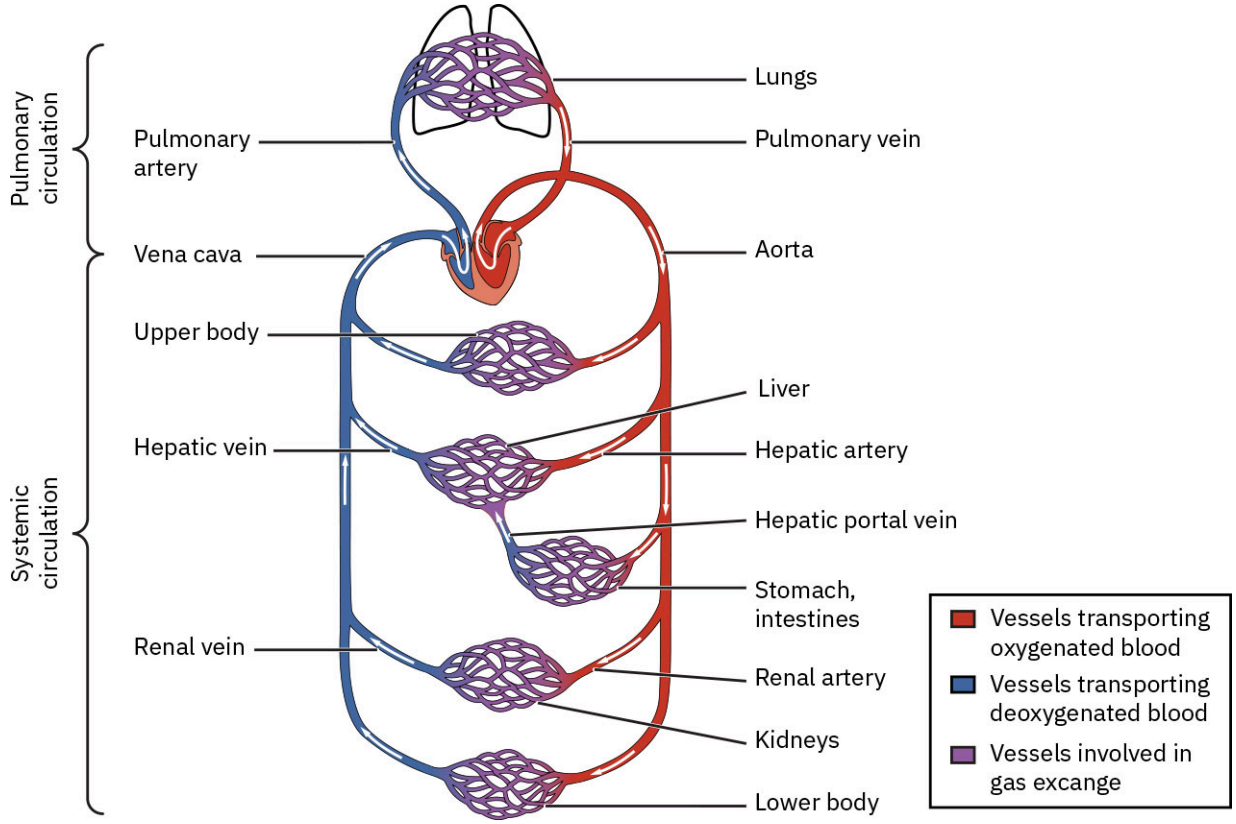

FIGURE 12.29 Peripheral vasculature supplies blood to the body and consists of pulmonary circulation and systemic circulation. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Arterioles direct blood flow to organs. They respond to systemic vascular resistance through dilation and constriction in response to the autonomic nervous system. Capillaries are very thin, fragile, single endothelial layered vessels that are the conduit between arterioles and venules. One example of capillary sites is fingers and toes. Venules connect from the capillaries to the veins, which assist in the return of deoxygenated blood to the heart (Tucker et al., 2023).

Pathophysiology

A chronic, progressive disorder, **peripheral vascular disease (PVD)** causes blood vessels outside of the heart and brain to narrow, block, or spasm; it affects both venous and arterial circulation. Chronic venous insufficiency, or **peripheral venous disease**, is compromised blood flow of the venous system, and peripheral arterial disease is compromised blood flow of the arterial system (Figure 12.30). Peripheral venous disease is more common in females and those who are older and have obesity (Rabe et al., 2020). While veins are supposed to return blood flow to the heart for re-oxygenation, noncompliant veins confront a flow issue and valvular incompetence causes

backward reflux into the vasculature of the legs (Weiss, 2020).

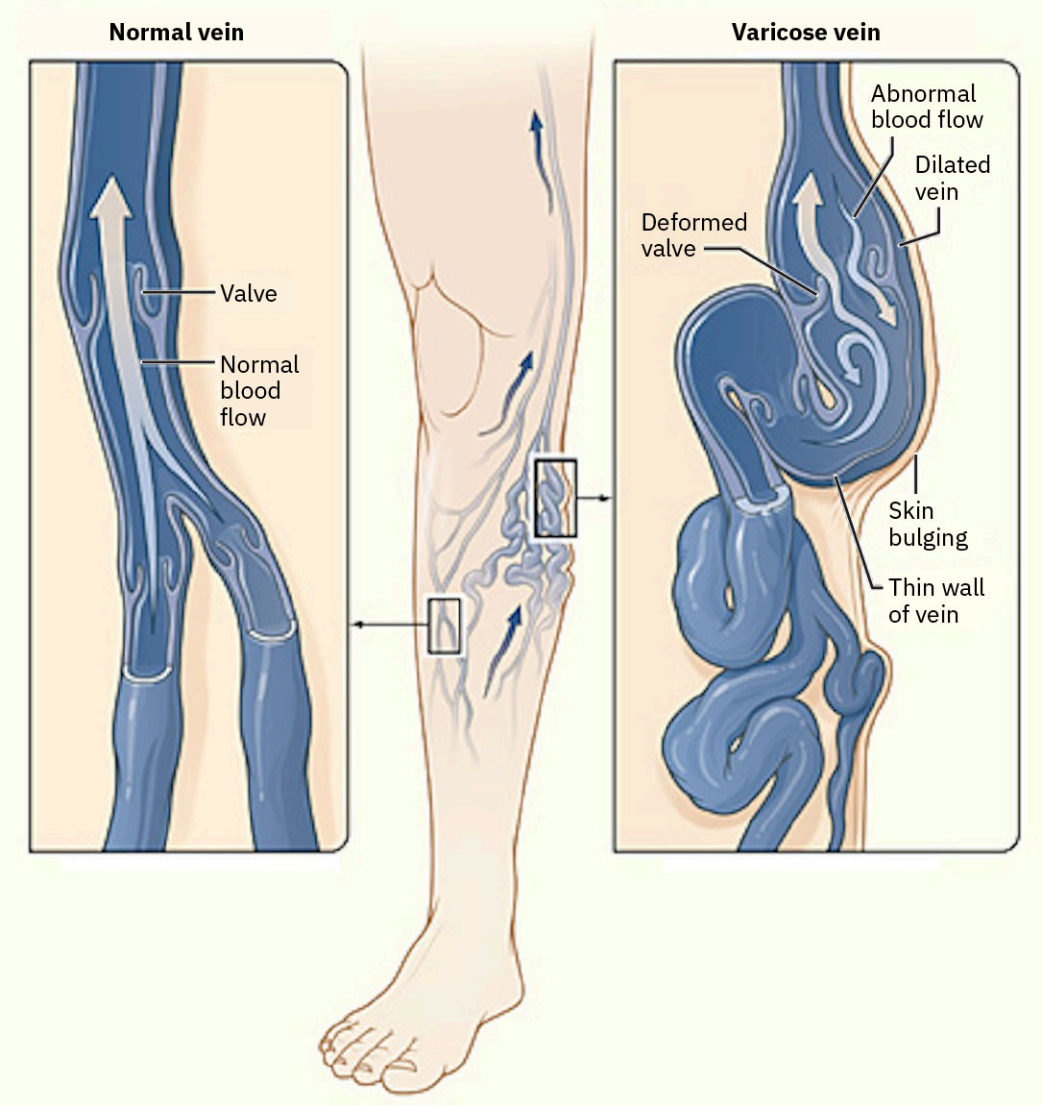

FIGURE 12.30 Venous insufficiency occurs when valvular incompetence causes blood flow back to the heart to be impeded. (credit: modification of "Varicose veins" by NIH: National Heart, Lung and Blood Institute, Public Domain)

Reduced blood flow from atherosclerotic blockages is known as **peripheral arterial disease**. When arterial blood is obstructed by narrowed, constricted vessels (Figure 12.31, the legs encounter a perfusion defect, and the patient may experience pain during ambulation, which is known as **intermittent claudication**. Peripheral arterial disease afflicts over 230 million people, who are older, smoke, and have other comorbidities of heart disease and diabetes (Aday & Matsushita, 2021). Both males and females over age 60 are affected equally by peripheral arterial disease (CDC, 2022). In patients with diagnosed coronary artery disease, aortic disease, or carotid artery disease, there is a high likelihood of peripheral arterial disease.

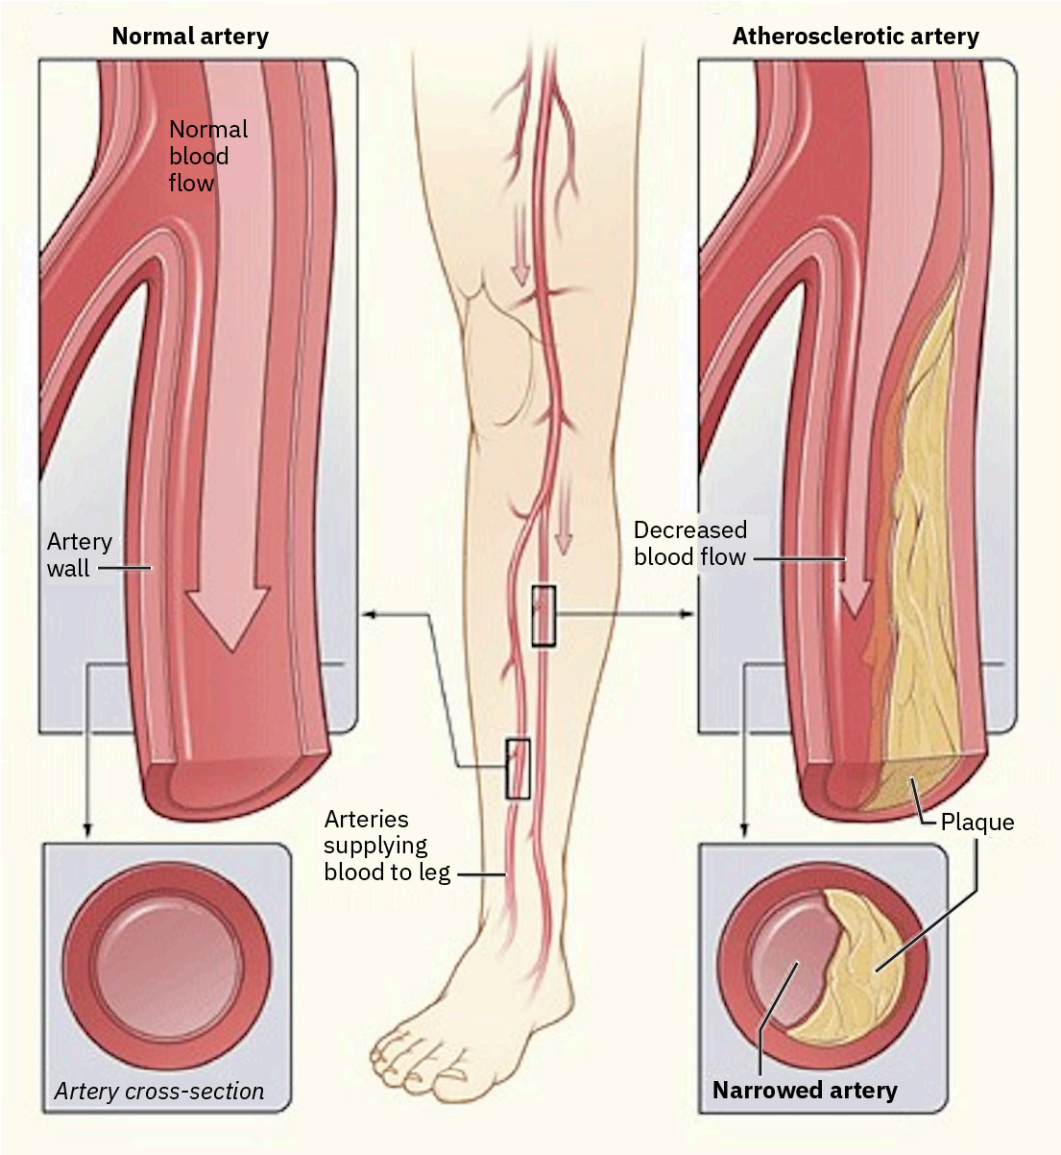

FIGURE 12.31 Arterial insufficiency occurs when arterial blood flow is reduced due to atherosclerotic blockages. (credit: modification of "Atherosclerosis in the leg arteries" by NIH: National Heart, Lung and Blood Institute, Public Domain)

Diagnostics and Laboratory Values

A patient with suspected peripheral vascular disease will first undergo noninvasive imaging with an ultrasound to visualize flow in the vessels. Another noninvasive method utilized is the ankle-brachial index (Figure 12.32), in which blood pressures are evaluated in the legs and arms at rest and after the patient walks on a treadmill on a slight incline. Discrepancies in the blood pressure will suggest a blood flow abnormality that is reproduced with activity. There are also invasive diagnostic tests, such as a peripheral angiogram, that may be performed. Risk stratification in identifying disease prevalence will be supported by elevated lipids (hyperlipidemia) and elevated hemoglobin A1C (diabetes).

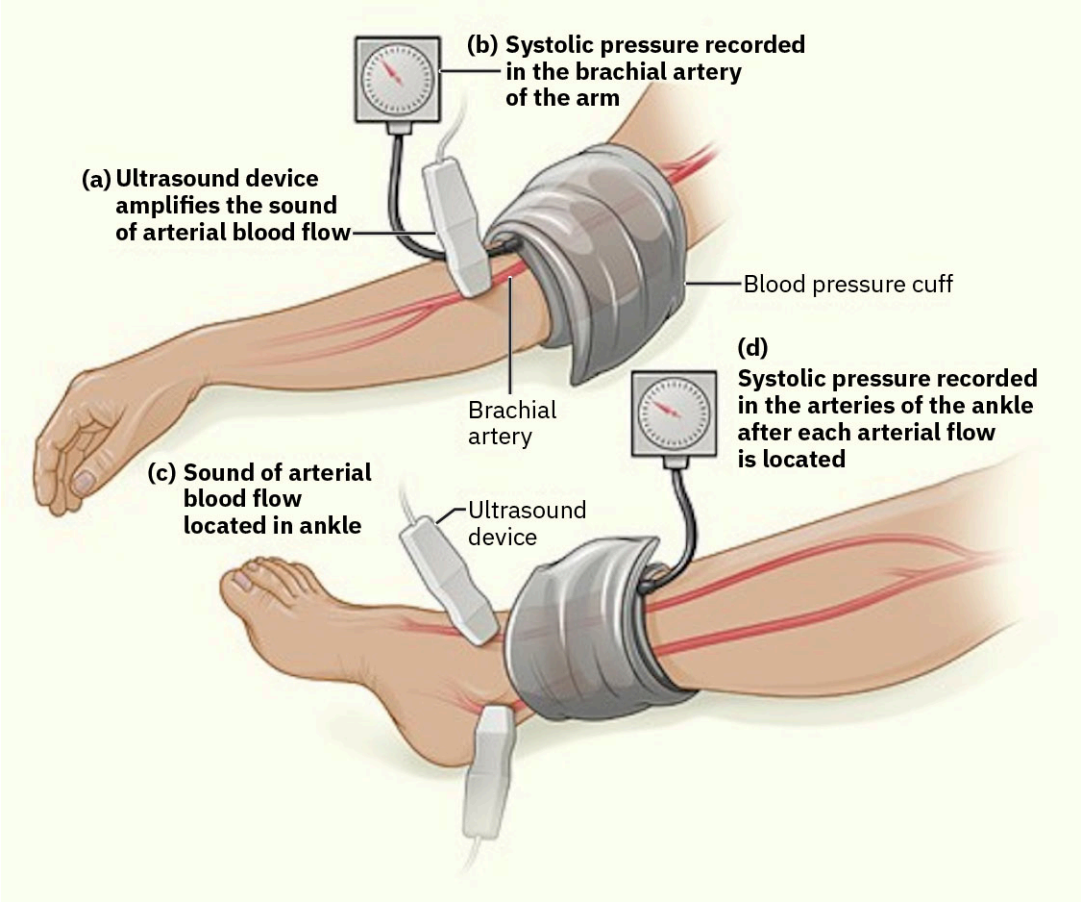

FIGURE 12.32 For the ankle-brachial index, blood pressure cuffs are applied to a patient's arms and legs. These pressures are taken after intermittent increases in incline and speed on a treadmill. The nurse will document if the patient has any pain in the legs as the test progresses. (credit: modification of "Atherosclerosis in the leg arteries" by NIH: National Heart, Lung and Blood Institute, Public Domain)

CLINICAL SAFETY AND PROCEDURES (QSEN)

QSEN Competency: Safety: Ankle Brachial Index

Disclaimer: Always follow the agency's policy for medication administration.

Definition: Minimize risk of harm to patients and providers through both system effectiveness and individual performance.

Knowledge: Examine human factors and other basic safety design principles as well as commonly used unsafe practices (such as workarounds and dangerous abbreviations).

Skill: Use appropriate strategies to reduce reliance on memory (such as forcing functions and checklists). The nurse will:

1. Take a baseline blood pressure of the patient's bilateral arms and legs.
2. Have the patient walk for several minutes on a treadmill with a slight incline.
3. Take another series of blood pressure measurements.
4. Have the patient repeat the treadmill walk at a slightly faster pace and higher incline.
5. Document any symptoms of intermittent claudication. In a positive result, the pressures will reduce with incremental increases in the incline and speed of the treadmill, while also noting if the patient reports pain in the legs with activity.

Attitude: Value the contributions of standardization/reliability to safety.

(QSEN Institute, n.d.)

Venous Insufficiency: Clinical Manifestations and Nursing Care

Veins in the lower extremities that struggle to return blood back to the heart for reoxygenation and recirculation likely have incompetent valves causing venous blood to pool. When this occurs, the patient may report cramping and aching in the legs, or pain that worsens with standing and relieved with rest. Edema may be observed, and **varicose veins** may be evident on assessment (Figure 12.33). The nurse must assess the warmth of the extremity, noting the character of the pulses and the color of the extremity. Note the patient's hair distribution, the presence of varicose veins, and nail integrity; nail beds may be raised, thick, and discolored. In patients with darker skin tone, assessing for capillary refill in the great toe may assist with identifying a vascular compromise. At times, a **venous stasis ulcer** may surface along the medial and lateral distal part of the leg (Figure 12.34). These wounds may have a shallow depth and irregular shape with a periwound of brown or yellow and may be painless.

FIGURE 12.33 Varicose veins may be visible in the lower legs of patients with venous insufficiency. The skin may be discolored, and nails may be thick and discolored. (credit: "Varicose veins affecting the lower leg Wellcome L0061800" by Wellcome collection: St Bartholomew's Hospital Archives & Museum/Wikimedia Commons, CC BY 4.0)

FIGURE 12.34 A venous stasis ulcer may occur in venous insufficiency. The yellow periwound tissue indicates necrotic tissue. (credit: "Archivo:Venous ulcer dorsal leg" by Jonathan Moore/Wikimedia Commons, CC BY 3.0)

The patient is encouraged to change positions often to avoid prolonged standing. Wearing compression stockings will assist with venous return; if not, the patient may have to rest and elevate their legs on a pillow. Hydration is critical to avoid pooled venous blood from aggregating. The patient may need an interprofessional referral to a wound care or vascular specialist for venous stripping of painful varicose veins. For edema of 3 to 4+, a diuretic may be recommended to assist with removal of excess fluid.

Arterial Insufficiency: Clinical Manifestations and Nursing Care

Decreased perfusion to the limbs due to atherosclerotic changes will create intermittent claudication. On assessment, the affected limb may feel cold to touch, pulses may be weak, and the skin will exhibit color changes such as pallor or decreased capillary refill due to insufficient blood getting to the limbs from arterial insufficiency. Shiny skin and a lack of hair will occur due to poor perfusion to the extremities. Similar to venous insufficiency, arterial ulcers may appear; however, they are centralized to the toes, heels, and ankles and other bony prominences. Arterial ulcers are rounder and more circular than venous ulcers and have minimal to no drainage (Figure 12.35).

FIGURE 12.35 Arterial ulcers are rounder and more circular than venous ulcers and have minimal drainage. They are more likely to appear on the toes, heels, ankles, and other bony prominences. (credit: "Arterial ulcer peripheral vascular disease" by Jonathan Moore/Wikimedia Commons, CC BY 3.0)

Interventions will be focused on educating the patient to limit excess ambulation to avoid intermittent claudication. Patients are encouraged to avoid high-cholesterol foods and stop smoking to prevent further vasoconstriction. Wound care may be ordered to assist with dressings and wound debridement. Chronic pharmacological management will consist of statin therapy to avoid further plaque formation.

Evaluation of Nursing Care of the Patient with Peripheral Vascular Disease

The following goals are examples the nurse may consider when evaluating care:

- The patient will report reduced pain or increased activity to physical limits with ambulation.
- The patient's wounds will reduce in size and be free of signs and symptoms of infection.
- The patient will participate in an exercise regimen.
- The patient will display reduced edema and report increased comfort.
- The patient will return a demonstration of elevating legs for pain management.
- The patient will demonstrate compliance with a healthy lifestyle and adherence to the medication regimen.

Depending on disease severity, goals may require adjustment to reflect the status of peripheral vascular disease. Ultimately, independence, physical capabilities and comfort will guide goal creation for the patient.

REAL RN STORIES

Nurse: Melinda, RN
Years in Practice: Four
Clinical Setting: Cardiovascular unit of a community hospital
Geographic Location: Midwestern U.S.

As a staff nurse for several years on a cardiovascular floor, I was familiar with patient presentation of peripheral vascular disease. I eventually transitioned to an outpatient women's health clinic, extending care to pregnant patients. Many of my patients reported painful swollen legs with evidence of varicose veins. Some of my patients were nurses as well. There was one patient who was 34 weeks-gestation and practiced as a critical care nurse. The patient found it difficult to stand for prolonged hours due to the swelling in her legs. I recounted my own experience, recalling similar struggles in my own pregnancy with painful varicose veins and swelling. With collaboration of my practice manager, we were able to collect compression stockings and circulate them to the patients who had venous insufficiency or varicose veins. I gave my patient, the critical care nurse, a pair of compression stockings. When the patient came in for her weekly follow up, she reported reduced swelling and pain in her legs. Simple education and personal experience were helpful for the patients I treated.

Medical Therapies and Related Care

Medical therapies include pharmaceuticals, including statins and antiplatelet/anticoagulation agents, hypertension management if present, diabetes management if present, exercise, and smoking cessation as necessary. More severe cases of arterial insufficiency may require surgical intervention such as angiography, endovascular repair, or arterial bypass (Figure 12.36).

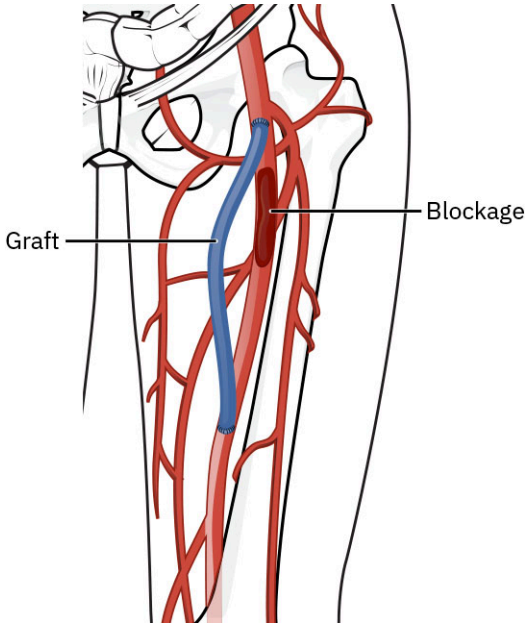

FIGURE 12.36 An arterial bypass restores blood flow by bypassing a diseased artery. (modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Summary

12.1 Cardiovascular Overview

- The coronaries perfuse the myocardial tissue with oxygen-rich blood. There are four chambers of the heart. Valves between the chambers communicate between the aorta and pulmonary veins.
- Blood starts on the right side of the heart, getting perfused to the lungs to get oxygenated, and returns to the left atrium, where it is expelled from the left ventricle to the body.
- Cardiac output is how much blood is exiting the aorta each minute.
- Stroke volume is the amount of blood that exits the left ventricle during systolic contraction.
- Preload and afterload are terms that encompass the amount of stretch and force that is required prior to contraction and during contraction, respectively.

12.2 Dysrhythmia

- Myocardial cells generate action potential and stimulate neurological impulses to cause contraction.
- Bradycardia is a slow heartbeat, less than 60 bpm. If slow enough, the patient may report dizziness or near syncope. Interventions may require discontinuing medications that are causing this issue. If the patient is asymptomatic, no intervention may be required.
- Tachycardia is a heart rate of over 100 bpm, and may be due to exercise, fever, stress, or pain. If a tachycardia dysrhythmia occurs, medications may be required.
- Ectopic beats are premature beats that occur in either the ventricles or atria. One common cause is excessive caffeine consumption.
- Heart blocks range from first, second, and third degree. Depending on the degree of heart block, monitoring of aggressive interventions such as pacing may be required.
- Atrial dysrhythmias are fast and can be regular or irregular. Treatments include medications, cardioversion, or ablation.
- Ventricular dysrhythmias are more life-threatening and require resuscitative efforts such as CPR and the use of the AED.
- Asystole rhythm shows a flat line with little to no evidence of cardiac rhythm and requires resuscitative efforts such as CPR.
- Nursing care will center around the type of dysrhythmia and if perfusion has been restored.

12.3 Heart Failure

- Pathophysiology of HF can be linked back to modifiable and nonmodifiable risk factors. The most common cause of HF is coronary artery disease and/or coronary artery blockage.
- Right-sided heart failure manifests when increased fluid pushes fluid back into the pulmonary system, congesting the right side of the heart and causing the right ventricle to fail. Left-sided heart failure manifests from left ventricular failure and cannot effectively pump blood throughout the body.
- Clinical manifestations of HF include dyspnea, edema, orthopnea, chest pain, cough, and weight gain.
- Nursing interventions of HF include daily weights, keeping the head of the bed in high Fowlers, clustering care, monitoring medication adherence, and educating patients on modifiable risk factors.
- Common pharmacological therapies include ACE inhibitors/ARBs, beta-blockers, diuretics, and nitrates.

12.4 Hypertension

- Hypertension, often known as the “silent killer,” is a preventable disease, but has paramount effects on overall health.
- Uncontrolled blood pressure has been linked with stroke, heart failure, myocardial infarction, kidney disease, and death.
- Hypertensive urgency includes symptoms of headache, blurred vision, and chest pain, while malignant hypertension are these symptoms plus target organ damage.
- To obtain accurate blood pressure readings, measurements should be taken on two different occasions using a properly sized cuff. The patient should be positioned in a comfortable environment and should refrain from eating or smoking for 30-45 minutes prior to the assessment.
- Interventions for hypertension center around the education of risk factors, medication compliance, lifestyle

changes, and evaluating appropriate responses to therapies. Therapies are initially aimed at diet, exercise, and weight loss. If lifestyle modifications are ineffective, pharmacological therapies are implemented.
- Nursing care includes teaching about reduced sodium intake, education on lifestyle modification, and assessment of medication effects.
- When evaluating outcomes, the patient should have a reduction of blood pressure readings or verbalization about making lifestyle modifications.

12.5 Myocardial Infarction

- MI events have a high mortality rate and morbidity rate if not appropriately addressed.
- Ischemia occurs when there is a temporary lack of blood flow, but is restored by medications and rest, whereas infarction is tissue death from a completely occluding thrombus.
- Risk stratification by identifying high-risk individuals, thorough medical history, and medication reconciliation (certain medications can cue the nurse if the patient has a history of MI) is paramount to eliminate occurrence of a cardiac event.
- Symptoms of MI include chest pain, shortness of breath, jaw pain, fatigue, palpitations, or nausea.
- Urgent interventions center around revascularization and administration of medications to dilate coronaries and prevent further platelet aggregation.
- Nursing interventions are gauged at optimizing oxygenation, reducing cardiac workload, and improving survivability.
- Evaluation of care is dependent on the patient's degree of infarction. More invasive and aggressive interventions may be required for STEMI compared to NSTEMI. The care and evaluation are tailored to the patient's diagnosis and clinical presentation.

12.6 Vascular Disorders

- Arteriosclerosis and atherosclerosis can cause narrowing of the arteries and reduced blood flow due to plaque formations.
- Carotid artery disease may or may not cause symptoms depending on the severity of the blockage, or the number of vessels blocked. Comorbidity management influences the risk of vascular disease incidence.
- Small AAA may be asymptomatic, but larger ones will cause cool clammy skin, diaphoresis, dizziness, fainting, tachycardia, nausea and vomiting, shortness of breath, and severe, sudden abdominal pain.
- Nursing responsibilities include hemodynamic stabilization, pre- and post-monitoring of patients undergoing revascularization procedures, and education on lifestyle adjustments.
- Medical management is first-line therapy with lifestyle modifications and adherence to medications. Surgical intervention is necessitated when blockages advance or vascular rupture is evident.

12.7 Peripheral Vascular Disease

- The peripheral vascular system comprises veins that return blood to the heart, arteries that bring blood away from the heart, and arterioles.
- The pathophysiology of venous insufficiency is that blood cannot return to the heart as efficiently and pools with bluish discoloration, whereas in arterial insufficiency, blood is not getting to the limbs efficiently, manifesting with pain, altered pulses, and diminished hair growth.
- Comorbidity management influences the risk of peripheral vascular disease incidence.
- Diagnostics include ultrasound, ankle-brachial index, and labs to identify risk factors.
- Nursing responsibilities include pain management, activity restriction, medication management, wound care, and surgery if indicated.
- Evaluation of goals center around reduction of wounds, ability to participate in exercise, and adherence to healthy lifestyle.
- Medical management is first-line therapy with lifestyle modifications and adherence to medications. Surgical intervention is necessitated when blockages advance.

Key Terms

abdominal aortic aneurysm (AAA) aorta in the abdomen is clogged with plaque, so it balloons out in an attempt to keep the blood flowing

ablation procedure that creates scars in the heart tissue that block the abnormal electrical impulses to help the heart maintain a normal rhythm

acute coronary syndrome (ACS) umbrella term that includes the following: non-ST-elevated myocardial infarction (NSTEMI), ST-elevated myocardial infarction (STEMI), and unstable angina

afterload amount of pressure the heart needs to exert during ventricular contraction

aneurysm enlargement of an artery, due to weakened wall from high velocity flows of blood

angina chest pain or discomfort that occurs when blood flow to the heart is reduced

angiography procedure in which a catheter is threaded into the femoral artery and fluoroscopy dye is injected into the patient's coronaries to assess the presence of coronary blockages

arteriosclerosis widespread hardening of the arteries

asystole cardiac activity ceases to occur due to termination of electrical conduction

atherosclerosis form of arteriosclerosis in which there is narrowing and reduced blood flow through the arterial wall due to plaque formations

atrial depolarization interval between the P wave and the R wave in the QRS complex; measurement of the time needed for electricity to travel from the atria to the ventricles

atrial fibrillation (AFib) irregular, fast cardiac rhythm originating from the atria with multiple impulses being fired

atrial flutter (A flutter) atrial dysrhythmia that has a regular but tachycardic rhythm caused by electrical re-entry in the right atrial circuity; classic "saw tooth pattern"

bruit "swooshing" sound

cardiac output number of liters of blood that exit the aorta in a minute

cardiomegaly ventricular enlargement to accommodate excess fluid

cardioversion procedure performed by a machine or medicine that restores a normal heart rhythm when the heart is beating too fast or irregularly

carotid artery disease condition that occurs when the carotid arteries become narrowed or blocked by the presence of plaque; also known as carotid artery stenosis

congestive heart failure (CHF) chronic condition that reduces perfusion to the body because the heart works inefficiently; commonly called heart failure (HF)

coronary artery bypass graft (CABG) surgical procedure in which veins from other parts of the body are placed over diseased coronaries to restore blood flow

creatine kinase MB (CK-MB) enzyme that is leaked during a myocardial infarction and is a blood test used in the diagnosis of a myocardial infarction

diaphoresis excessive sweating

dyspnea difficulty breathing

echocardiogram digital image that offers visualization of valve competency, filling pressures, measurements of ventricular thickness, and compliance of the ventricles

ectopic beat occasional, singular, irregular beat that may originate from the atria or the ventricles

ejection fraction measure of ventricular compliance, expressed as a fraction

first-degree heart block cardiac rhythm in which the PR interval is consistently greater than 0.20 seconds while QRS is normal and regular

hepatosplenomegaly liver and spleen enlargement from excess fluid

hypertensive urgency when a patient has a blood pressure over 160/90 mm Hg and has symptoms of headache, shortness of breath, blurred vision, or chest pain

infarction death of tissue due to a lack of perfusion

intermittent claudication leg pain during ambulation caused by a perfusion defect due to narrow, constricted arteries

ischemia temporary blockage of blood through an artery due to blockage

left ventricular hypertrophy compensatory thickening of the ventricle due to increased myocardial stress and increased pressure

left-sided heart failure left ventricle muscle is damaged and weak and can no longer pump enough blood through the body

malignant hypertension the same features as hypertensive urgency, but with signs of target organ disease, such as kidney failure or heart failure

Mobitz I second-degree heart block cardiac rhythm in which the PR interval gets longer with each beat until a

QRS is dropped, and the pattern repeats

Mobitz II second-degree heart block heart rhythm in which the PR interval remains constant, but some of the QRSs are randomly dropped

normal sinus rhythm cardiac rhythm originating from the sinus node that describes the characteristic rhythm in the healthy human heart

orthopnea difficulty breathing while lying flat

pacemaker electrical device surgically implanted to regulate an abnormal heartbeat

peripheral arterial disease compromised blood flow of the arterial system

peripheral vascular disease (PVD) chronic, progressive disorder that causes blood vessels, both venous and arterial, outside of the heart and brain to narrow, block, or spasm

peripheral venous disease compromised blood flow of the venous system

preload initial stretch of the cardiac cells prior to contraction

premature atrial contraction (PAC) ectopic beat originating from the atrium that causes an early, irregular occurrence of P and QRS waves

premature ventricular contraction (PVC) ectopic beat originating from the ventricle that causes an early, irregular occurrence of a wide QRS wave

primary hypertension hypertension that is multi-factorial and does not have one distinct cause; also called essential hypertension

right-sided heart failure increased fluid pushes fluid back into the pulmonary system, and congests the right side of the heart, causing the right ventricle to fail

secondary hypertension hypertension caused by another medical condition, such as thyroid issues or adrenal or kidney disease

sinus bradycardia cardiac rhythm with a rate less than 60 bpm, with regular PR and QRS intervals

sinus tachycardia cardiac rhythm with a rate greater than 100 bpm, with regular PR and QRS intervals

stroke volume amount of blood pumped out of the left ventricle during systolic contraction

supraventricular tachycardia (SVT) umbrella term utilized to discuss rhythm disturbances that occur above the ventricles

third-degree heart block loss of electrical impulses between the atria and the ventricles

transcutaneous pacing noninvasive procedure that uses electrical impulses to temporarily pace a patient's heart

troponins proteins that leak during a myocardial infarction, can be measured from a blood test

varicose veins due to venous insufficiency, veins may "pop" out more and can be painful

venous stasis ulcer ulcer that can form due to venous insufficiency

ventricular depolarization measurement of time electricity travels through the ventricles to conduct a ventricular contraction and is represented by the QRS complex

ventricular fibrillation potentially life-threatening cardiac rhythm in which the ventricle beats rapidly at over 200 bpm; chaotic with no discernible QRS, PRs, or P waves

ventricular tachycardia potentially life-threatening cardiac rhythm in which the ventricle beats rapidly at 150 to 200 bpm, with wide QRS complexes and no discernible PRs or P waves

Assessments

Review Questions

1. From what heart chamber will deoxygenated blood be delivered to the lungs for oxygenation?

a. right atrium
b. right ventricle
c. left atrium
d. left ventricle

2. What term defines the amount of stretch myocardial cells must employ prior to a contraction?

a. stroke volume
b. automaticity
c. preload
d. afterload

3. What factors affect cardiac output? Select all that apply.

a. gender
b. age
c. heart failure
d. education level
e. previous hospitalization

4. In an ECG, what would represent electrical activity conducted by the atria?

a. QRS
b. PR interval
c. T wave
d. P wave

5. What is not a risk factor for bradycardia?

a. opioid overdose
b. third-degree heart block
c. avid distance runner
d. smoking

6. What would most likely trigger an ectopic dysrhythmia?

a. potassium 4.0 mmol/L
b. magnesium 2.2 mg/dL
c. decaffeinated tea
d. coffee

7. A patient was found pale, short of breath, and in rapid atrial fibrillation at 120 beats per minute. The patient successfully cardioverted. What evaluation would the nurse anticipate to know the treatment was effective?

a. Patient reports dizziness upon standing.
b. The patient's blood pressure is 88/48 mm Hg.
c. The patient's apical pulse is regular.
d. The patient's capillary refill is 3+.

8. A patient has been newly diagnosed with atrial fibrillation. What factor would put the patient at risk for developing a blood clot? Select all that apply.

a. history of hyperlipidemia
b. age 76 years
c. history of heart failure
d. history of hypertension
e. female gender

9. What comorbidity most commonly elevates the risk of HF development? Select all that apply.

a. MI
b. HTN
c. aortic dissection
d. obstructive sleep apnea

10. What is a gold standard test for diagnosing HF?

a. echocardiogram
b. chest X-ray
c. electrocardiogram
d. cardiac catheterization

11. What response should a patient display if they are having a therapeutic response to diuretics?
   a. potassium 4.0 mmol/dl
   b. weight increase of 2 lbs
   c. unchanged orthopnea
   d. increased ease of breathing

12. How do nitrates assist patients with HF?
   a. preload reduction
   b. afterload reduction
   c. coronary vasoconstriction
   d. ventricular remodeling

13. What cue would the nurse expect to recognize in heart sounds for a patient in HF?
   a. murmur
   b. regular rate and rhythm
   c. bradycardia
   d. pericardial click

14. What outcome would the nurse expect for the patient on diuretic therapy for HF?
   a. The patient's weight will be reduced by 2 lbs.
   b. The patient will liberally drink fluids.
   c. The patient will have to work through moments of fatigue during activities of daily living.
   d. The patient will take the medication with a blood pressure of 88/48 mm Hg.

15. What is a modifiable risk factor that places a patient at risk for developing hypertension?
   a. diabetes insipidus
   b. a low-sodium diet
   c. obesity
   d. female

16. What is the pathophysiological function that causes the blood to be hypercoagulable?
   a. endothelial dysfunction
   b. arteriolar dilation
   c. increased autonomic nervous system activity
   d. reduced serum angiotensin

17. What medication therapy is indicated for Black patients for hypertension?
   a. loop diuretics
   b. alpha receptor blockers
   c. ACE inhibitors
   d. beta-blockers

18. What is an example of a statement made by the nurse that demonstrates education about modifiable risk reduction to control high blood pressure?
   a. "You're all set because you quit smoking."
   b. "It's okay to continue with excessive coffee since that does not affect blood pressure."
   c. "It is recommended to abstain from alcohol."
   d. "Completing sixty minutes of physical activity per week should help with your blood pressure."

19. A nurse is conducting an educational session on dietary changes for a patient newly diagnosed with hypertension. What statement made by the patient would indicate the teaching was effective?
   a. "I will reduce my intake of 2 bowls to one bowl of ice cream every night."
   b. "I will continue to drink red wine."

c. "I will monitor how much salt I am eating."
d. "I will increase my fluid intake."

20. What coronary artery perfuses the sinoatrial node, known as the "pacemaker" of the heart?
a. right coronary artery
b. left circumflex artery
c. left main coronary artery
d. left anterior descending artery

21. What is true about stable angina?
a. worsens with rest
b. lasts several minutes
c. reversed with rest
d. worsens despite pharmacological intervention

22. What finding or findings represents STEMI? Select all that apply.

a. there are no ECG changes
b. elevation in troponins
c. there are ECG changes
d. elevation in CK-MB levels
e. does not require emergent angiography

23. A patient has acutely ruled in for NSTEMI and will be proceeding to angiography in a few hours. What medications would the nurse anticipate for this patient? Select all that apply.

a. Simvastatin
b. Losartan
c. Metoprolol
d. Heparin
e. Clopidogrel

24. What cue would the nurse recognize to be consistent with MI?
a. pulse 64 bpm
b. normal sinus rhythm
c. 120/64 mm Hg
d. 82/40 mm Hg

25. What clinical manifestation represents carotid artery disease?
a. nausea
b. vomiting
c. leg pain
d. vision changes

26. What populations are at risk for venous insufficiency? Select all that apply.

a. males
b. females
c. obese
d. thin
e. Age 65 years old or older

27. What is the noninvasive diagnostic test for identifying peripheral vascular disease?
a. ankle-brachial index

b. angiography
c. blood pressure
d. CT scan

28. What would the nurse want to include in the education for a patient with venous insufficiency?
a. avoid wearing compression stockings
b. movement will relieve leg pain
c. elevate their legs on a pillow
d. avoid hydration to minimize edema

29. What are the characteristics of arterial ulcers? Select all that apply.

a. present on heels and toes
b. round
c. large amounts of serous drainage
d. shallow
e. minimal to no drainage

Check Your Understanding Questions

1. Differentiate between preload and afterload.

2. What is the difference between a bradycardic and tachycardic dysrhythmia?

3. Describe the nursing interventions when a patient goes into asystole.

4. What is the term for the force of blood the ventricle must overcome to eject the blood?

5. What is the term for a compensatory thickening of the ventricle?

6. If a patient's ejection fraction is over 70%, what is this known as?

7. When the diseased ventricle is unable to eject blood forward, what is this known as?

8. What nonmodifiable risk factor has a similar prevalence for hypertension?

9. What may a patient with hypertension and evidence of edema have an underlying diagnosis of?

10. What is widespread, systemic hardening of the arteries is known as?

11. What pharmacological therapy would the nurse anticipate using to prevent further plaque formation in the intima layer of the vessel?

Reflection Questions

1. How would a nurse discuss the difference between a cardio-selective versus a non-cardio-selective beta blocker to a graduate nurse?

2. A patient calls their primary care clinic stating home blood pressure readings have been elevated with an average of 164/98 mm Hg. How should a nurse counsel the patient?

3. A patient 30 days following an MI and placement of a stent in the LAD is following up with a cardiologist. How would the nurse evaluate the patient recovering from MI?

4. A patient with a diagnosed AAA is scheduled to go for a diagnostic angiography. How would a nurse preceptor explain the purpose of this test to a new graduate?

5. A patient has recently undergone a carotid endarterectomy three months earlier. The clinic nurse is reviewing the labs. How would the nurse evaluate the laboratory values responding to pharmacological therapies?

6. How would the nurse educate the patient on the difference between varicose veins and venous stasis wounds?

Critical-Thinking Questions about Case Studies

1. Refer to COVID Complications: Part 2.
   Which of the choices is the patient at risk of developing? Select all that apply.

   A. fever
   B. dysrhythmias
   C. decreased cardiac output
   D. seizures
   E. deceased ejection fraction
   F. hemorrhagic stroke

2. Refer to COVID Complications: Part 2.
   Explain why troponins are being measured in this patient.

Competency-Based Assessments

1. Based on the following rhythm strip, what is the nurse's first intervention?

(attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

   A. Administer atropine.
   B. Administer lidocaine.
   C. Continue to monitor.
   D. Continue to monitor with pacer pads close by.

2. Review the literature and find an article on how nurses assist a patient with HF and evaluate the patient's response in cardiac rehab.
3. Conduct a literature search and look at the clinical manifestations of angina between males and females.
4. Consult the literature and find a current article that discusses the outcomes of wound care of peripheral vascular wounds.

CHAPTER 13
Musculoskeletal System

FIGURE 13.1 The musculoskeletal system includes bones, joints, muscles, tendons, and ligaments. It is responsible for protecting internal organs and facilitating body movements. (credit: daverose215/flickr, CC BY 2.0)

CHAPTER OUTLINE

INTRODUCTION You are a nurse assessing a 65-year-old female patient, Ms. Chen, in a nursing home. Ms. Chen recently experienced a hip fracture that required a total hip-replacement surgery. She was discharged back to her original facility from the hospital two days ago and has been struggling with mobility. She reports being nervous to use her walker because that is how she fell and fractured her hip. You reassure Ms. Chen that you are here to assess her needs and provide care that will help her regain comfort with ambulation, mobility, and performing activities of daily living (ADLs). This chapter will help you learn how to support patients like Ms. Chen by completing a nursing assessment of the musculoskeletal system and managing common disorders of the musculoskeletal system.

13.1 Osteoporosis and Osteopenia

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for osteoporosis and osteopenia
- Describe the diagnostics and laboratory values of osteoporosis and osteopenia
- Apply nursing concepts and plan associated nursing care for patients with osteoporosis and osteopenia
- Evaluate the efficacy of nursing care for patients with osteoporosis and osteopenia
- Describe the medical therapies that apply to the care of osteoporosis and osteopenia

The musculoskeletal system comprises bones, joints, muscles, tendons, and ligaments. Its major function is promoting body **mobility**, the ability of a patient to change and control their body position. Physical mobility requires sufficient muscle strength and energy, along with adequate skeletal stability, joint function, and neuromuscular synchronization. Anything that disrupts this integrated process can lead to impaired mobility or immobility. Mobility exists on a continuum ranging from no impairment (i.e., the patient can make major and frequent changes in position without assistance) to complete immobility (i.e., the patient is unable to make even slight changes in position without assistance) (Figure 13.2). Functional mobility assessment tools can help determine the level of a patient's mobility.

FIGURE 13.2 Mobility varies over time and can be affected at any time due to injury or illness. (credit: modification of "Retirement Image" by Ben Baligad/Flickr, CC BY 2.0)

LINK TO LEARNING

The Johns Hopkins Highest Level of Mobility (JH-HLM) Scale (https://openstax.org/r/77JH-HLMScale) measures the patient's highest level of mobility achieved.

The bone disease **osteoporosis** is caused by caused by a significant decrease in bone density and mass. This disease presents a major threat to public health, with almost 54 million Americans affected (International Osteoporosis Foundation, 2023). A decrease in bone mineral density, **osteopenia** is the precursor condition to osteoporosis; it currently affects nearly 34 million Americans. Females are four times more likely to be affected than males, and the incidence is higher in postmenopausal females (Varacallo et al., 2023). The prevalence of these conditions is significant, as they often result in serious bone fractures, which can pose significant health problems, especially to already at-risk populations such as older adults.

Pathophysiology

The underlying pathophysiology of osteoporosis involves too much **resorption**, or the breakdown and reabsorption over time of small amounts of minerals from the bone; the minerals are broken down and reabsorbed into the systemic circulation. Without replacement and remodeling of the removed parts, bone weakness and fragility occur, resulting in osteopenia and eventually osteoporosis (Figure 13.3). Risk factors for the development of osteopenia

and osteoporosis include

- advanced age,
- certain medical conditions (e.g., cancer, HIV, anorexia nervosa),
- chronic alcohol use,
- cigarette smoking,
- family history of osteoporosis,
- female sex,
- hormonal changes (e.g., low estrogen levels after menopause),
- long-term use of certain medications (e.g., corticosteroids, proton pump inhibitors, antiepileptic medications),
- low body mass index (BMI),
- physical inactivity or prolonged immobility, and
- poor dietary habits (e.g., inadequate calcium, vitamin D, or protein).

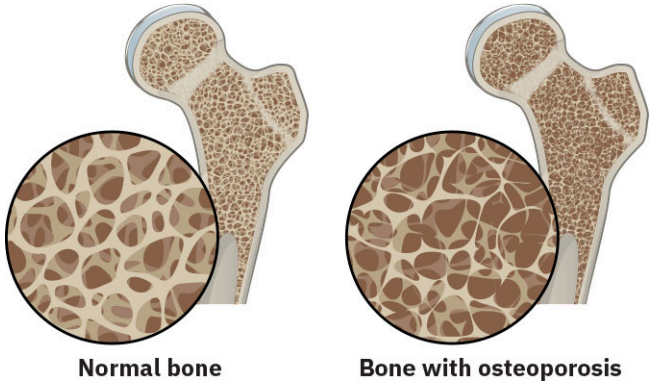

FIGURE 13.3 This diagram illustrates osteoporosis by comparing a normal leg bone and a leg bone with missing bone fragments. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

LIFE-STAGE CONTEXT

Osteoporosis Risk in Older Females

The risk of developing osteoporosis is significantly higher in females when compared to males. Most of this risk is associated with estrogen levels. Estrogen acts as a bone protectant, so when hormonal levels decrease dramatically, such as during menopause, the rate of bone breakdown is accelerated, resulting in the development of osteoporosis (National Health Service, 2022).

Clinical Manifestations

Due to the progressive bone weakness that occurs with osteopenia and osteoporosis, clinical manifestations may not become evident until the individual experiences a bone fracture. The most common fractures associated with osteoporosis include fractures of the hip, lumbar spine, and wrist. Another common clinical manifestation of osteoporosis, especially in older adults, is a loss of height (usually an inch or two) due to **kyphosis**, or excessive curvature of the upper spine. This occurs secondary to the gradual breakdown of the vertebrae over time, causing the individual to stand with a "hunched over" posture (Figure 13.4). Other clinical manifestations include pain in the lower back and shortness of breath, both related to vertebral body compression (National Institute of Arthritis and Musculoskeletal and Skin Diseases, 2022).

FIGURE 13.4 Kyphosis, an abnormal curvature of the upper spine, is commonly associated with osteoporosis. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Assessment and Diagnostics

The physical assessment of a patient with osteopenia or osteoporosis often reveals a kyphotic posture, as well as a decrease in total height over the course of several years. This highlights the importance of obtaining baseline measurements and completing accurate documentation so that data collected on subsequent visits may be compared to the earlier assessments. Additionally, it is important to complete a risk assessment for fractures for any patient who has been diagnosed with or is at risk for osteoporosis. A commonly used risk assessment tool is the Fracture Risk Assessment Tool (FRAX), which analyzes risk factors including age, sex, height, weight, family history, and alcohol use, among others. This tool helps calculate the risk for experiencing a bone fracture in patients with osteoporosis and is used to guide treatment planning.

LINK TO LEARNING

The Online Fracture Risk Assessment (FRAX) Tool (https://openstax.org/r/77FRAXTool) allows a patient to input data directly into the calculator and obtain a risk-assessment score.

Diagnostics and Laboratory Values

There are several diagnostic tests that can be used to confirm a diagnosis of osteopenia or osteoporosis. The gold standard test is the dual-energy x-ray absorptiometry (DEXA or DXA) scan. This procedure uses low-dose–radiation x-rays to determine bone density of the hip, wrist, or spine (Figure 13.5). Once a value is obtained, it is compared to standard values for an individual with similar demographic characteristics to determine the presence and severity of osteoporosis. It is currently recommended that all individuals assigned female at birth who are over the age of 65 have a DXA scan; females with specific risk factors should consider obtaining a scan before the age of 65 so that early intervention and treatment may be initiated (U.S. Preventative Services Task Force, 2018). In the later stages of osteoporosis, regular x-rays may be used to monitor the progression of the disease. While no laboratory values are specific to confirming a diagnosis of osteoporosis, several laboratory tests—such as testing vitamin D, calcium, albumin, and phosphate levels—can be used to rule out other medical conditions.

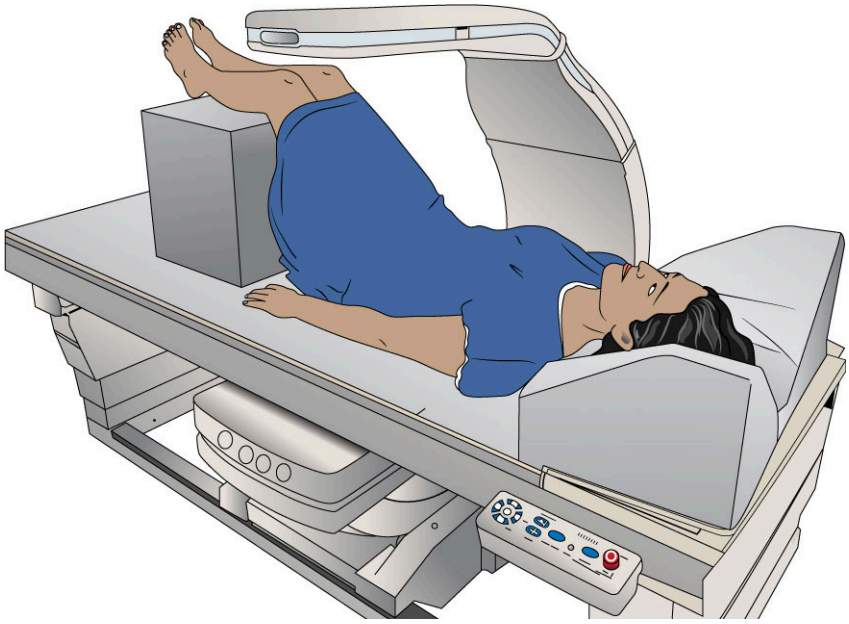

FIGURE 13.5 The DXA scanner machine scans the bone density of a patient's hip bones and spine. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Nursing Care of the Patient with Osteoporosis and Osteopenia

Nursing care of patients with osteopenia or osteoporosis occurs in many areas, including both outpatient and inpatient settings. Typically, this condition can be managed on an outpatient basis, but there may be a need for inpatient hospitalization, especially in the later stages of the disorder if major bone fractures occur.

Recognizing Cues and Analyzing Cues

First and foremost, nurses must be able to recognize risk factors specific to osteoporosis—such as sex, age, and medical history—when obtaining a complete health history from their patients. Upon recognition of these risk factors, the nurse can make appropriate recommendations and referrals for further testing and treatment as needed. The nurse should also be mindful of physical symptoms of osteoporosis, including kyphosis, loss of height, and patient-reported back pain.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

If any risk factors or physical assessment findings indicate the development of osteoporosis, the nurse will mention them to the provider, and it is likely that further diagnostic testing will be conducted. Once these tests have confirmed the diagnosis of osteoporosis, the nurse will assist in implementing treatment interventions, providing patient education, and ensuring appropriate follow-up appointments. One of the main nursing interventions for patients with osteoporosis is providing education, especially as it relates to lifestyle changes that the patient can make to slow the progression of the disorder. Common nursing interventions for patients with osteoporosis include

- promoting patient independence,
- assisting with activities of daily living (ADLs) as needed,
- encouraging physical mobility as tolerated,
- providing education regarding the importance of calcium and vitamin D intake as well as dietary sources
- referring the patient to a dietician as needed,
- encouraging smoking cessation, and
- implementing fall-risk precautions as needed.

Evaluation of Nursing Care for the Patient with Osteoporosis and Osteopenia

It is important for nurses to follow up with patients to ensure that treatment outcomes are achieved. If they are not, the nurse will work closely with the provider and other members of the health-care team to revise the patient's plan of care.

Evaluating Outcomes

The nurse will evaluate several outcomes that indicate treatment goals for osteoporosis are being met. These outcomes include

- improved patient knowledge regarding the condition and its associated treatments,
- pain relief (especially in the back), and
- no new bone fractures.

To evaluate these outcomes, the nurse will employ the following strategies:

- conduct pre- and post-education knowledge assessments to determine whether the patient has gained knowledge about their condition and treatments;
- implement a validated pain assessment tool to measure pain intensity before and after pain management interventions; and
- review medical records to track and identify any new fractures or signs of fractures since the initiation of treatment.

Medical Therapies and Related Care

Treatment options for osteopenia and osteoporosis often involve a combination of lifestyle modifications and pharmacological interventions (Table 13.1).

Treatment	Rationale
• Lifestyle modifications • Smoking cessation • Reduced alcohol consumption • Regular, weight-bearing, physical activity as tolerated • Increased dietary intake of calcium and vitamin D	Risk factors for osteoporosis should be addressed through lifestyle modifications because most of the risk factors are modifiable.
Vitamin supplements (if not enough are obtained from dietary intake)	Calcium and vitamin D may help reduce the risk of bone fractures.
• Bisphosphonates (e.g., alendronate risedronate, ibandronate) • Typically the first-line pharmacological treatment option	These medications work by inhibiting osteoclasts to slow the progression of osteoporosis. (An **osteoclast** is a cell that breaks down bones.)
Selective estrogen receptor modulators (SERMs) (e.g., raloxifene)	These medications mimic the effects of estrogen in the body to preserve bone marrow density.
RANKL inhibitors (e.g., denosumab)	This monoclonal antibody increases bone marrow density and inhibits the action of osteoclasts.

TABLE 13.1 Treatment Options for Osteopenia and Osteoporosis

LINK TO LEARNING

Bisphosphonates are typically the first line treatment for osteoporosis, so it is important for nurses to educate patients about their potential side effects (https://openstax.org/r/77bisphosphon) and other care conditions. For example, this type of medication should be taken with a full glass of water, and the patient should remain upright for one hour after taking it to prevent upper-GI conditions such as esophagitis and dyspepsia.

13.2 Osteoarthritis

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for osteoarthritis
- Describe the diagnostics and laboratory values of osteoarthritis
- Apply nursing concepts and plan associated nursing care for patients with osteoarthritis
- Evaluate the efficacy of nursing care for patients with osteoarthritis
- Describe the medical therapies that apply to the care of osteoarthritis

The most common form of arthritis, **osteoarthritis (OA)**, is a degenerative joint disorder that involves the wearing down of joint cartilage and tissue over time. OA currently affects over 32.5 million Americans (Arthritis Foundation, n.d.). The joints most often affected include those in the hands, knees, spine, neck, and hips (Figure 13.6). Though joint damage cannot be reversed or cured, symptoms can usually be managed effectively with a combination of pharmacological and lifestyle interventions. In more severe cases, surgical intervention may be required. OA can be diagnosed at any age, but it is more common in individuals over the age of 50.

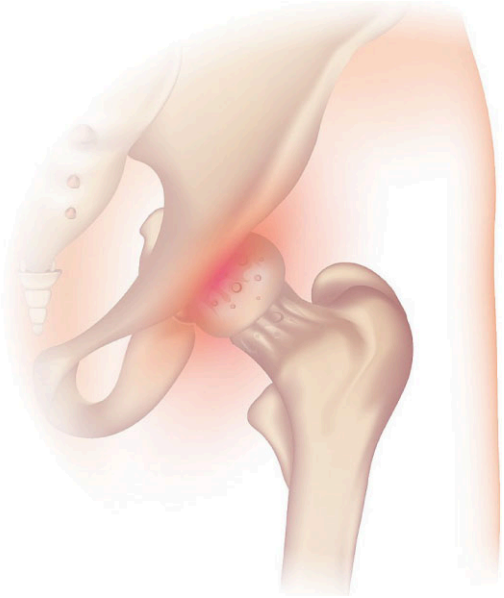

FIGURE 13.6 Osteoarthritis of the hip joint involves the wearing down of the joint cartilage over time, causing pain. (credit: Hip Osteoarthritis by Injurymap/Wikimedia Commons, CC BY 4.0)

Pathophysiology

The pathophysiology of OA is somewhat unknown, but it appears to involve inflammation that results in the breakdown of joint cartilage over time. OA causes the cartilage to gradually become thinner, and as the cartilage layer wears down, more pressure is placed on the bones. The joint responds by increasing production of the synovial fluid for more lubrication, but this can cause swelling of the joint cavity. The bone tissue underlying the damaged articular cartilage also responds by thickening and causing the articulating surface of the bone to become rough or bumpy. As a result, joint movement results in pain and inflammation. Certain factors have been linked to an increased risk of developing OA, including

- advanced age,
- family history of OA,
- female sex,
- history of joint injury,
- obesity,
- overuse of joints (e.g., from sports or repetitive motions), and
- sedentary lifestyle.

Clinical Manifestations

The main clinical manifestation of OA is joint pain, which is often more apparent during activity or at the end of the day. Other common clinical manifestations of OA include

- joint stiffness, most often occurring first thing in the morning or after long periods of immobility;
- limited joint range of motion or flexibility;
- muscle weakness;
- joint instability (e.g., knee "giving out");
- "grating" sensation with joint movement, which may be accompanied by a "popping" or "clicking" sound;
- a bony projection that develops along bone edges, known as a **bone spur** (Figure 13.7); and
- joint swelling.

FIGURE 13.7 This x-ray image shows a bone spur that has developed on the heel of the foot. (credit: "Achilles insertional calcific tendinosis" by Mikael Haggström/Wikimedia Commons, CC0)

Assessment and Diagnostics

The first step of diagnosing OA is to conduct a thorough physical examination. It is important to obtain a subjective report from the patient about their symptoms. Specifically, the nurse should ask about any joint pain or stiffness, as this may indicate the presence of OA. The nurse will also perform passive range of motion exercises and assess for pain, limited movement, and abnormal popping or clicking sounds. If symptoms of OA are present, other diagnostic tests may be indicated. Certain imaging tests such as x-ray or magnetic resonance imaging (MRI) can be used to visualize the joint space and determine the presence of cartilage breakdown and changes in the bone associated with OA. Joint aspiration, also known as **arthrocentesis**, is another diagnostic test that may be indicated in some cases. This procedure involves the insertion of a needle into the joint space to remove fluid, which is then tested for infection or crystals. Arthrocentesis may assist in ruling out other conditions such as gout, rheumatoid arthritis, or lupus (Figure 13.8).

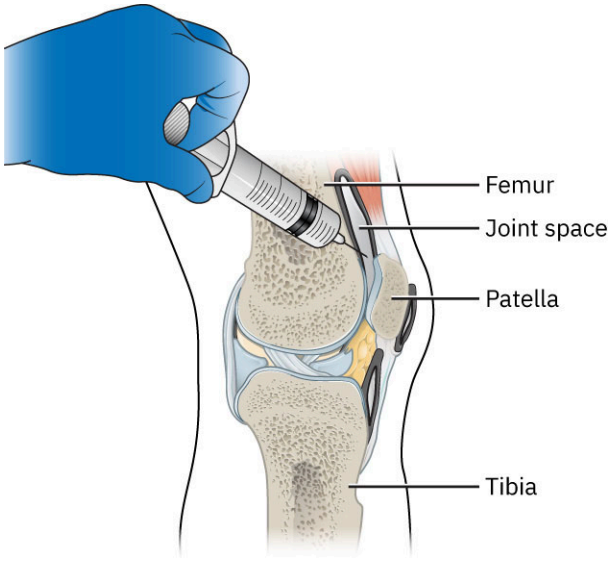

FIGURE 13.8 This arthrocentesis procedure is being performed on a knee joint. After using a needle to remove fluid from the joint space, the fluid is tested for infection or crystals. (credit: modification of work from *Anatomy and Physiology*, 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Diagnostics and Laboratory Values

Because OA is an inflammatory condition, laboratory values indicating the presence of general inflammation can be used to assist in the diagnosis. Specifically, there is usually an elevation in both C-reactive protein and erythrocyte sedimentation rate (ESR). These laboratory tests cannot determine specifically where the inflammation is occurring, but they do confirm that inflammation is occurring somewhere in the body.

Nursing Care of the Patient with Osteoarthritis

Most of the nursing care for patients with OA centers around providing pain control and ensuring patient comfort. This includes administering analgesics as ordered by the provider and implementing comfort measures such as heat or cold application, position changes, and range of motion (ROM) exercises. ROM exercises can be classified as active or passive; active movements are achieved voluntarily by patients, without assistance, while passive movements are performed by the nurse or other practitioners because patients are unable or not permitted to move the body parts themselves.

Recognizing Cues and Analyzing Cues

When caring for a patient with OA, the nurse will monitor closely for symptoms indicating that the condition is becoming more severe or requires more intensive treatment. In addition to patient-reported joint pain, the nurse should regularly assess for joint swelling or tenderness. OA can occur in any joints, but swelling is usually most obvious in the hands (Figure 13.9).

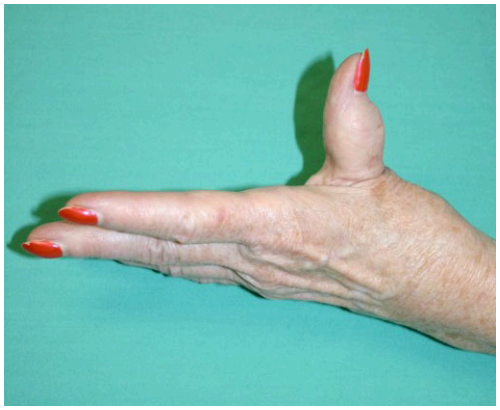

FIGURE 13.9 Osteoarthritis can cause swelling of the finger joints. (credit: thumb arthritis - radial abduction by handarmdoc/Flickr, CC BY 2.0)

Prioritizing Hypotheses, Generating Solutions, and Taking Action

In addition to medication administration and implementation of comfort measures, the nurse also provides emotional support for the patient with OA. Living with OA can be difficult and may negatively affect many aspects of life, including the patient's ability to perform their own ADLs. This results in diminished independence and a need for assistance, something that may be hard for the patient to come to terms with. The nurse should help the patient create a plan of care that emphasizes independence and allows for the patient to perform as many personal care activities and ADLs as possible to increase their quality of life. The nurse could consult occupational therapy for adaptive devices to help the patient perform their ADLs.

Evaluation of Nursing Care for the Patient with Osteoarthritis

It is important for the nurse to follow-up with the patient to ensure their plan of care and treatments are effective. In some cases, medications or comfort measures may not be adequately providing pain relief, indicating the need for more invasive interventions such as surgical joint replacements.

REAL RN STORIES

Nurse: Ansu
Years in Practice: Twenty-one
Clinical Setting: Inpatient rehab
Geographic Location: Florida

Skin integrity prevention is easy to implement: offload any pressure area to avoid breakdown. However, there are many factors at play that can interfere with a plan for prevention, such as medications, a patient's mobility, and pain. One preventative measure is to engage the patient, which allows you to get a little creative.

One time I was caring for an 87-year-old female. She was in the unit for rehab after a fall. She had been experiencing osteoarthritis for the last 12 years. She was shaken up and very nervous about being able to move around without assistance and unable to simply reposition due to chronic pain, which can increase the risk of skin breakdown. If her pain prevented her from repositioning frequently, however, then her skin would break down. I explained to her the importance of repositioning and movement for not only her skin care but also her overall health and recovery. We discussed why she was fearful and devised a plan we called a safety-first plan. The first day, our goal was that every time she was in the chair, she would reposition every 30 minutes by leaning to the side and then back again to the other side, three to four times. I also educated her on how to use a walker for additional support, which helped empower her to move and slowly gain confidence for the larger-scale rehab required.

Evaluating Outcomes

The nurse should evaluate patient outcomes to determine whether the current plan of care is appropriate. Outcomes indicating that the plan of care is appropriate and the patient is improving include

- pain relief,
- decreased joint swelling,
- increased ROM of affected joint,
- increased muscle strength, and
- patient usage of effective coping strategies.

Medical Therapies and Related Care

Treatment for OA involves a combination of pharmacological and nonpharmacological lifestyle interventions (Table 13.2).

Medication	Rationale
Acetaminophen (e.g., Tylenol)	Assists with mild to moderate pain associated with OA
Nonsteroidal anti-inflammatory drugs (NSAIDs)	Assists with mild to moderate pain associated with OA and has anti-inflammatory effects
Duloxetine (e.g., Cymbalta)	Shown to improve chronic pain associated with OA
Glucocorticoid joint injections	thought to improve joint inflammation, though the benefits of chronic, long-term use are controversial

TABLE 13.2 **Pharmacological Treatment Options for OA**

CLINICAL SAFETY AND PROCEDURES (QSEN)

QSEN Competency: Safety

Definition: Minimize risk of harm to patients and providers through both system effectiveness and individual performance.

Skill: Demonstrate effective use of strategies to reduce risk of harm to self or others. The nurse will

- provide education to patients with OA about the use of NSAIDs, as overuse of NSAIDs has been linked to an increased risk of GI bleeding, especially in OA patients; and
- provide education to patients to mitigate the risk of this adverse effect.

(QSEN Institute, n.d.)

Certain nonpharmacological lifestyle changes are also indicated in the treatment of OA. These include

- weight loss,
- regular physical activity and exercise,
- ROM exercises,
- use of assistive devices (e.g., braces, shoe inserts),
- use of adaptive devices (e.g., elevated toilet seats, hygiene devices),
- physical and occupational therapy, and
- relaxation and stress-reduction techniques.

If lifestyle and pharmacological interventions are not effective, surgery may be indicated. Specifically, joint replacement surgery has been shown to be effective for the treatment of OA. Hip and knee joint replacements are the most-performed surgical procedures for OA.

13.3 Bone Fractures

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for bone fractures
- Describe the diagnostics and laboratory values associated with bone fractures
- Apply nursing concepts and plan associated nursing care for patients with bone fractures
- Evaluate the efficacy of nursing care for patients with bone fractures
- Describe the medical therapies that apply to the care of bone fractures

A break in the bone structure, or a bone **fracture**, is one of the most common types of musculoskeletal traumas. Worldwide in 2019, 178 million fractures occurred, in addition to 455 million existing cases of acute or chronic symptoms related to a fracture (GBD 2019 Fracture Collaborators, 2021). Fractures affect the entire population, regardless of demographic factors such as age or sex. However, certain risk factors are associated with different

types of fractures. For example, older adults are at higher risk for experiencing hip fractures than their younger counterparts.

Pathophysiology

The underlying pathophysiology of fractures involves stress placed on a bone that results in a break in the bone's structure. Several different forces can result in bone fractures, including direct trauma, twisting movements, and crushing forces. Some of the most common causes of fractures include motor vehicle accidents, sports injuries, and falls. Usually when a bone fracture occurs, the soft tissue surrounding the bone is also affected. This can result in edema, hemorrhage, tendon damage, and severed nerves—all collectively referred to as soft tissue injuries.

Types of Fractures

Fractures are classified by their complexity, location, and other features (Figure 13.10; Table 13.3). Some fractures have the features of more than one type of fracture and therefore may be described using more than one term (e.g., an open transverse fracture).

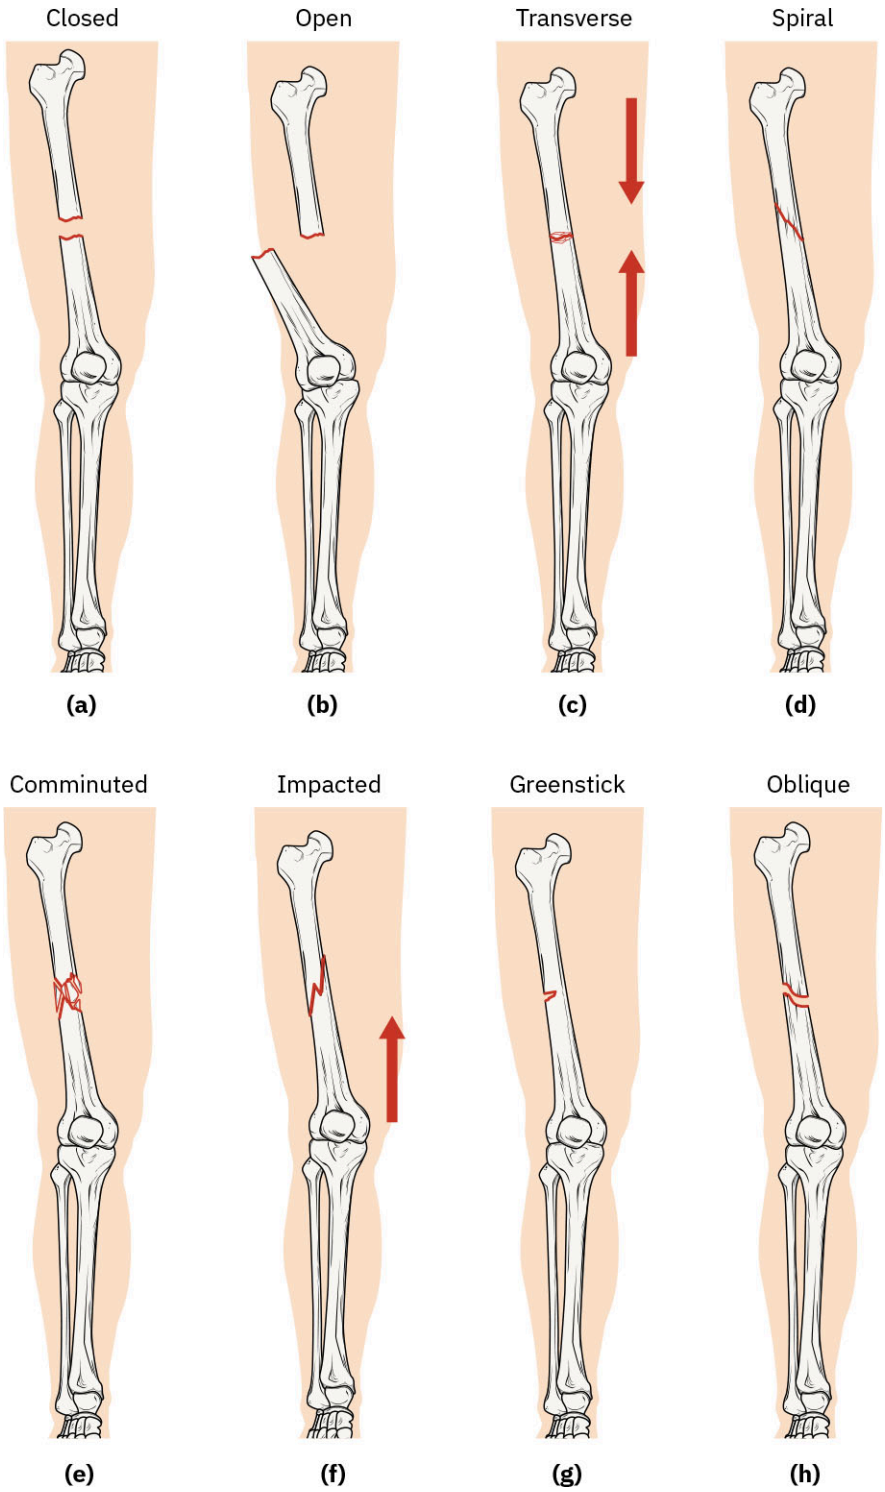

FIGURE 13.10 There are several types of fractures: (a) closed fracture, (b) open fracture, (c) transverse fracture, (d) spiral fracture, (e) comminuted fracture, (f) impacted fracture, (g) greenstick fracture, and (h) oblique fracture. (credit: modification of work from *Anatomy and Physiology*, 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Type of Fracture	Description
Closed (or simple)	Fracture in which the skin remains intact
Comminuted	Fracture with several breaks, resulting in many small pieces between two large segments
Greenstick	Partial fracture in which only one side of the bone is broken
Impacted	Fracture in which one fragment is driven into the other, usually as a result of compression
Oblique	Fracture that occurs at an angle that is not 90 degrees
Open (or compound)	Fracture in which at least one end of the broken bone tears through the skin; carries a high risk of infection
Spiral	Fracture in which bone segments are pulled apart by a twisting motion
Transverse	Fracture that occurs straight across the long axis of the bone

TABLE 13.3 Types of Fractures

Clinical Manifestations

The specific clinical manifestations of fractures will vary depending on the anatomic location affected, but there are certain symptoms associated with nearly all fracture types, including

- pain and tenderness,
- edema,
- inability to move the affected body part,
- bruising or hematoma formation, and
- deformity of the affected extremity.

Assessment and Diagnostics

The only definitive way to diagnose a bone fracture is to visualize the break in the bone structure. This can be done with several different types of imaging tests, including x-ray, magnetic resonance imaging (MRI), and computed tomography (CT) scanning. X-rays are typically performed first, as they can quickly and easily visualize bone structure. A CT scan or MRI may be used if there are suspected soft tissue injuries that the provider or surgeon needs to see in more detail.

READ THE ELECTRONIC HEALTH RECORD

Assessment of a Patient with a Tibia Facture

Patient's Name: Jaun
Age: 17 years
Sex: Male
Chief Complaint:

- pain in the left lower leg after collision playing hockey
- presents with the inability to bear weight and deformity of the left lower leg

Medical History:

- diagnosed with concussion two years ago: sport (hockey) injury
- forty-two stitches applied to chin last year: sport (hockey) injury
- tonsillectomy at age four

Vital Signs:

- temperature: 93.3 °F
- heart rate: 132 bpm
- blood pressure: 152/94 mm Hg
- respiratory rate: 32 breaths per minute
- oxygen saturation: 98 percent on room air
- BMI: 28

Recent Laboratory Results:

- WBC count: 10,000/µL (normal)
- hemoglobin: 13.5 g/dL (normal)
- hematocrit: 40.5 percent (normal)
- platelets: 250,000/µL (normal)
- electrolytes:
- sodium: 138 mmol/L (normal)
- potassium: 4.0 mmol/L (normal)
- chloride: 102 mmol/L (normal)

Imaging Results:

- Imaging includes full-length AP and lateral views of the affected area; also AP, lateral, and oblique views of the ipsilateral knee and ankle.
- Fracture noted to left distal tibia.

Progress notes:

- Patient reports sudden onset of sharp pain in lower leg after colliding with another player in a hockey game, followed by throbbing when attempting to walk.
- Mild diaphoresis was observed upon admission.
- Patient otherwise presents as an active young adult with no other health disparities.

Current medications:

- acetaminophen: 500 mg every night as needed for pain

1. What information in the patient's chart concerns you?
2. What is an expected finding?
3. What information should you obtain from the patient? What should you educate the patient about?

Nursing Care of the Patient with Bone Fractures

Most of the nursing care for patients with fractures focuses on controlling pain and ensuring patient comfort. It is also important for the nurse to assess for and intervene if complications develop such as **compartment syndrome**, a condition caused by increased pressure within an area of tissue and resulting in muscle and nerve damage (discussed more later in this section).

Recognizing Cues and Analyzing Cues

There are several key assessments the nurse should perform on patients with bone fractures. First, it is important for the nurse to perform frequent neurovascular examinations on the affected extremity. Neurovascular checks involve assessing the extremity for the 5 P's:

- pain (on a scale of 1 to 10);
- pulse (weak pulses may indicate insufficient blood supply to the affected extremity);
- pallor (pale, blue, or purple tone in the affected extremity may indicate compromised blood flow);
- paresthesia (numbness or tingling in the extremity may indicate nerve damage); and
- paralysis, or inability to move the affected extremity.

LINK TO LEARNING

Review this article to learn more about the 5 P's acronym (https://openstax.org/r/77FivePs) for circulation assessment.

In addition to frequent neurovascular checks, the nurse must also assess for signs and symptoms of an embolism. With fractures, especially those in the long bones like the femur, there is an increased risk that a fat embolism, or clot, will form. This occurs because the break in the bone allows pieces of fatty tissue to leak out into the systemic circulation. The fat embolism can travel through the body's systemic circulation, get lodged in the brain or lungs, and quickly cause a life-threatening ischemic stroke or pulmonary embolism. These clots most commonly develop between 24 and 72 hours after the initial fracture, so the nurse should monitor closely for signs of neurological changes or shortness of breath (Adeyinka & Pierre, 2022).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

If the nurse assesses symptoms such as shortness of breath, chest pain, or neurological changes following a fracture, the nurse will hypothesize that the patient is potentially experiencing a fat embolism. If this condition is suspected, the nurse must act quickly to mitigate complications. Priority actions would include notifying the provider, calling a rapid response team if indicated, and applying oxygen as necessary. Additionally, the nurse should carefully follow orders given by the treating provider, such as administering medication or providing other interventions.

There are many important nursing interventions that should be implemented as part of the care provided to patients with bone fractures. First, the nurse will attempt to promote mobility of the affected extremity as much as possible. Though the patient may be in a cast or splint, there are typically certain exercises the patient should perform to maintain as much mobility as possible. The nurse can help educate patients about these exercises and ensure that the patient is prepared to perform them on their own at home upon discharge.

Another important aspect of nursing care for these patients is education about how to care for their cast at home. If the cast is not made of a water-safe material, the nurse should demonstrate how to wrap the cast with plastic before taking a shower so that the plaster does not get wet and re-mold itself. The nurse will also counsel the patient on the importance of not sticking any foreign objects inside the cast. The skin underneath the cast tends to become dry and itchy, and patients are often tempted to stick items inside to scratch the skin and relieve the itching. This can result in skin breakdown and should be avoided while the cast is in place.

Evaluation of Nursing Care for the Patient with Fractures

After removal of the cast or splint, the nurse should perform a thorough assessment of the fractured extremity to determine whether the treatment was successful. In some cases, the patient may require another cast or splint placement, but in most cases the bone will have healed completely.

Evaluating Outcomes

While evaluating the patient after cast removal, the nurse will assess for signs indicating that the treatment was effective. These signs include

- lack of deformities to the bone or extremity,
- decreased swelling,
- improved pain,
- ability to move distal parts of the affected extremity,
- normal skin color, and
- strong pulse distal to the fracture.

Additionally, a follow-up x-ray will be performed to evaluate the healing status of the fracture and determine whether further treatment is indicated.

Medical Therapies and Related Care

The specific treatment plan for a bone fracture depends on the anatomic location of the affected area. In some

cases, the fracture will heal on its own; in other cases, more invasive interventions such as immobilization, reduction, fixation, or surgery may be required. In addition to the manual treatments mentioned in subsequent sections, it is also important for the nurse to promote a diet that will aid in the healing of the bone fracture. Encouraging the patient to consume a well-rounded, healthy diet that is high in protein, which assists in bone and tissue healing.

Immobilization

For mild fractures, immobilization of the fracture with a cast or splint may be all that is required. The duration of the immobilization varies depending on the affected bone, but it typically ranges anywhere from three to eight weeks. Splints cover only part of the affected area and typically do not have to be worn as long as hard casts.

Closed Reduction

More-severe fractures may require the use of a closed reduction procedure. The goal of this procedure is to set the fractured bone and realign it into a normal position. The provider manually adjusts the bone from the outside to line up the broken parts of the bone correctly (Figure 13.11). Because this procedure can be quite painful, the patient will often receive a combination of local anesthesia, sedatives, and analgesics. After closed reduction is performed, a cast or splint for immobilization is applied.

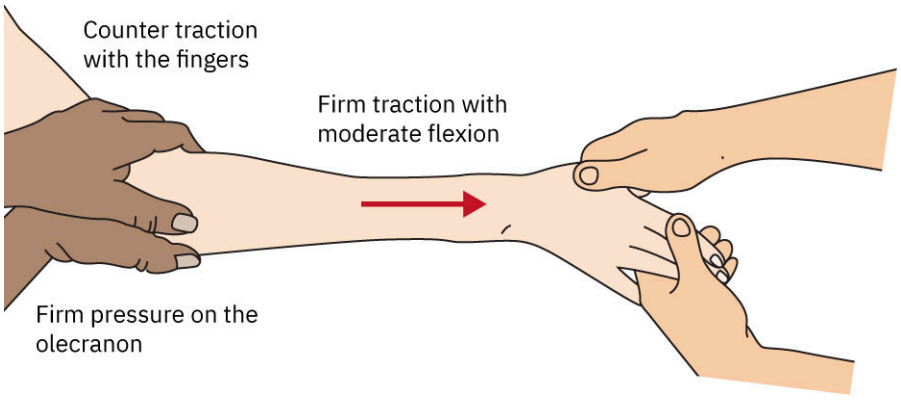

FIGURE 13.11 Closed reduction of a fracture of the lower arm requires traction and pressure on both ends to bring the bones in line. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Surgical Care

The most-severe fractures usually require surgical intervention. There are several types of surgery for fractures, including internal and external fixation and arthroplasty.

Internal Fixation

A surgery of **internal fixation** involves the placement of metal pieces into the bone to help it heal as it grows back together (Figure 13.12). The types of metal pieces vary depending on the fracture's location and size, but they can be rods, plates, screws, or pins. In some cases, the metal pieces are removed after healing occurs; in other cases, the metal pieces are left in place forever.

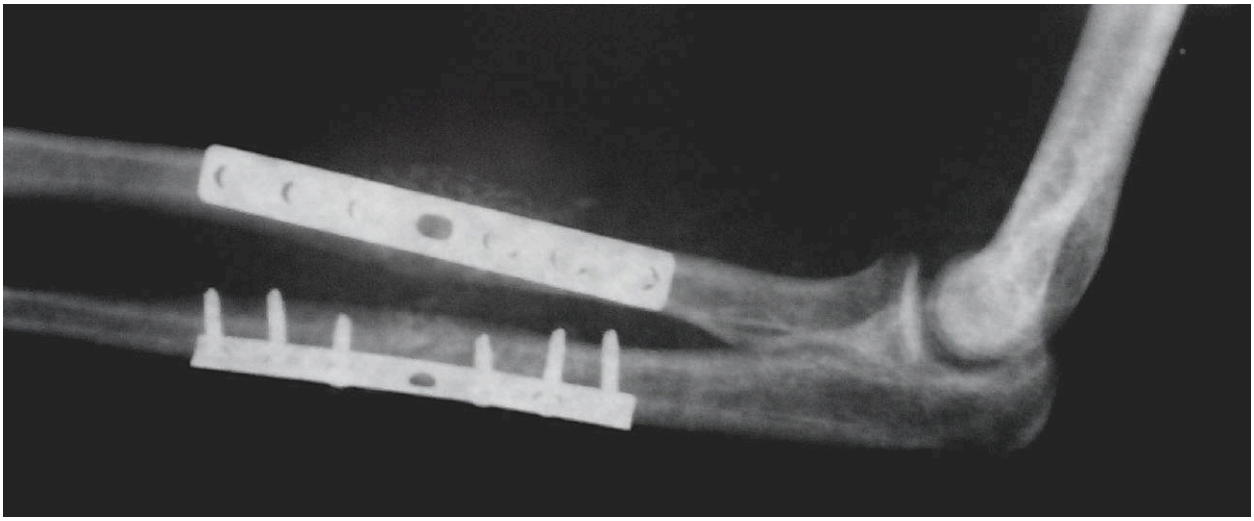

FIGURE 13.12 This x-ray shows an internal fixation of the radius and ulna. (credit: "X-ray3" by Mikael Haggström/Wikimedia Commons, Public Domain)

External Fixation

Another surgical procedure that can be performed to treat fractures is an **external fixation**, which involves the internal placement of screws on either side of the fracture by drilling pins into the bone and then connecting them to an external brace or bracket (Figure 13.13). The external brace is temporary but stays in place long enough for the fractured bone to heal. Typically, an internal fixation procedure is performed after removal of the external device to complete the healing process.

FIGURE 13.13 External fixation often requires a brace around the limb to stabilize the fracture and allow it to heal. ("Clinical picture showing the soft tissue defect healed at 6 months after the Papineau technique" by Koutsostathis et al./*Diabetic Foot and Ankle*, CC BY 2.0)

One of the most important aspects of nursing care for a patient with an external fixation device is performing meticulous pin care to prevent infection. The nurse should clean the pin sites daily with soap and water and dab to dry, as rubbing can create friction and skin breakdown. It is important for the nurse to monitor the pin sites carefully for signs of infection including redness, drainage, swelling, or pain. The nurse will follow any provider orders regarding special care, such as physical therapy or follow-up with the external fixator.

Arthroplasty

Joint replacement, known as **arthroplasty**, may be required if the fracture occurs in a joint such as the shoulder, elbow, hip, or knee. The fractured joint is removed from the body and replaced with an artificial joint, which is usually made of metal, plastic, or ceramic materials.

Compartment Syndrome

A common and serious complication that may occur with bone fractures and soft tissue injuries is compartment syndrome. With a fracture or injury to the surrounding tissue, pressure builds within the skin and muscles, leading to

decreased blood flow to the affected extremity (Figure 13.14). Without adequate blood supply, the extremity becomes malnourished and can quickly become necrotic without medical intervention. In severe cases, a **fasciotomy**, or incision into the skin and fascia to relieve pressure, will be required.

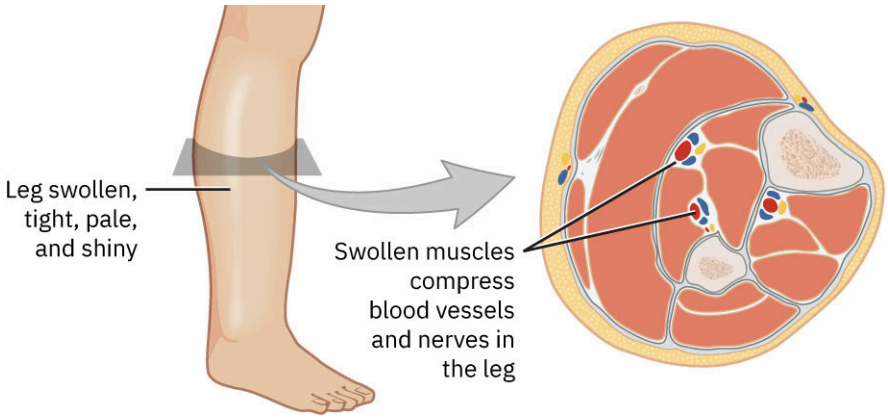

FIGURE 13.14 Compartment syndrome of the lower leg causes pressure to build within the skin and muscles, leading to decreased blood flow to the affected extremity. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Signs and symptoms of compartment syndrome include

- diminished distal pulses in the affected extremity,
- swelling and taut skin in the extremity,
- numbness or "pins and needles" feeling in the extremity, and
- difficulty moving the extremity.

If the nurse suspects that the patient is experiencing compartment syndrome, they must alert the treating provider immediately. If quick intervention does not take place, the limb is at risk of necrosis because the internal pressure of the extremity results in a diminished blood supply to the extremity.

13.4 Muscular Dystrophy

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for muscular dystrophy
- Describe the diagnostics and laboratory values of muscular dystrophy
- Apply nursing concepts and plan associated nursing care for patients with muscular dystrophy
- Evaluate the efficacy of nursing care for patients with muscular dystrophy
- Describe the medical therapies that apply to the care of muscular dystrophy

A **muscular dystrophy (MD)** is a rare genetic disorder that causes progressive muscle weakness over time (Figure 13.15). With over 30 specific types, MD has a wide range of variability in terms of age of diagnosis, severity, and affected muscles. However, all types are progressive, meaning they get more severe over time. Some of the more common types are briefly described in Table 13.4. In most cases, individuals diagnosed with MD will eventually be unable to walk and perform their own ADLs such as toileting or bathing.

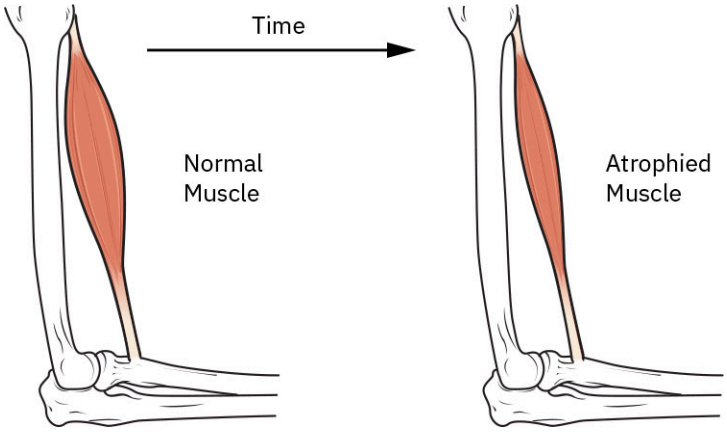

FIGURE 13.15 Progressive muscle weakness and atrophy occur over time with muscular dystrophy. (credit: modification of work from *Anatomy and Physiology*, 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Type	Description
Duchenne muscular dystrophy (DMD)	• DMD is the most-common type, affects 14 in 100,000 male individuals between the ages of 5 and 24. • It accounts for approximately half of the cases of MD. • It is an X-linked recessive genetic disorder, meaning that it primarily affects the male population. • It results from a complete absence of **dystrophin**, a protein involved in maintaining muscle strength and function. • Symptoms often become apparent during toddler years, when the child is beginning to walk.
Becker muscular dystrophy (BMD)	• BMD is less severe than DMD. • It results from insufficient function of dystrophin. • It usually appears around age 11, but it may occur as late as one's mid-twenties.
Myotonic dystrophy	• This is the most-common MD that is first diagnosed during adulthood (usually between 20 and 30 years of age). • It prevents muscles from relaxing following contraction.
Facioscapulohumeral muscular dystrophy (FSHD)	• FSHD affects the face, shoulders, and upper arms. • It often causes symptoms that affect the eyes first (e.g., difficulty opening eyelids). • Its onset is typically during adolescence, but it can be later. • Most affected individuals live a normal lifespan.
Limb-girdle muscular dystrophy (LGMD)	• LGMD results in progressive muscle loss and weakness, especially in the hips and shoulders. • Several different subtypes with varying levels of severity exist.

TABLE 13.4 Types of Muscular Dystrophies (Muntoni et al., 2023; National Institute of Neurological Disorders and Stroke, n.d.)

LIFE-STAGE CONTEXT

Muscular Dystrophy Diagnosis During Childhood

Most MDs are diagnosed during childhood, which increases the complexity of the disorder. The parents or caregivers of the child will be tasked with providing most of the care to the child in the home setting, highlighting the need for adequate education and training. Additionally, caregivers will likely need emotional support, as receiving a devastating diagnosis for their child can be life-altering. Nurses must not only treat the patient but also consider the needs of the parents and other involved caregivers and family members, such as siblings or grandparents.

Pathophysiology

The underlying pathophysiology of MD is caused by genetic mutations, either inherited or spontaneous. In most cases, the mutation that causes MD is inherited, meaning that it came from one or both parents. Though the specific pathophysiologic mechanism is still somewhat unknown, the mutation negatively affects muscle function, resulting in the degeneration of muscle fibers, decreased muscle mass, and progressive muscle weakness over time.

Clinical Manifestations

Clinical manifestations of MD vary depending on the specific type, but some of the more common findings include

- loss of reflexes,
- abnormal gait,
- frequent falls or clumsiness,
- difficulty standing from a sitting position or climbing stairs,
- posture changes,
- muscle weakness and atrophy,
- contractures,
- an abnormally curved spine, known as **scoliosis**,
- impaired breathing,
- enlarged calves, and
- inability to open or close the eyes.

Because most MDs are diagnosed in childhood, it is often the child's parents who notice the first signs that may indicate a muscular problem. Parents often report that their child is unable to run or jump, is "toe walking," falls frequently, or has trouble standing up from a sitting position on the floor.

Assessment and Diagnostics

The first step in diagnosing MD involves a thorough review of the patient's medical history. It is especially important to assess the patient's family history, as many MDs are known to be genetically inherited. Additionally, a comprehensive physical examination may reveal clinical manifestations associated with MD, including muscle weakness, abnormal gait, or posture changes.

Diagnostics and Laboratory Values

Because MD often occurs secondary to genetic mutations, genetic testing is one of the most definitive diagnostic tests for the condition. In some cases, muscle biopsies can be conducted to examine muscle tissue more closely for signs of the condition. Beyond genetic testing and muscle biopsies, there are no diagnostic tests specific to MD, but several other laboratory and diagnostic tests can be used to assist in making the diagnosis (Table 13.5).

Diagnostic Test	Expected Finding with Muscular Dystrophy
Serum creatine kinase (CK)	CK may be elevated due to muscle breakdown and damage.
Electrocardiogram (ECG)	Heart function may be altered or arrythmias may be present, especially in myotonic dystrophy.
Electromyography (EMG)	Changes in the pattern of muscular electrical activity may indicate a muscular disorder such as MD.
Pulmonary function tests (PFTs)	In more severe cases, PFTs reveal a suboptimal functioning of the lungs due to diaphragmatic muscle weakness.

TABLE 13.5 Diagnostic Tests Used to Assist in the Diagnosis of Muscular Dystrophy

Nursing Care of the Patient with Muscular Dystrophy

Most of the nursing care for patients with MD centers around maintaining the highest quality of life possible and minimizing the negative effects associated with progressive muscle weakness. While there is no definitive cure for MD, many nursing interventions seek to address specific challenges associated with muscle weakness, mobility issues, and potential complications (LaPelusa et al., 2024).

Recognizing Cues and Analyzing Cues

Because most cases of MD are diagnosed in childhood, it is often the parents who notice muscle abnormalities and bring in their children for further assessment and diagnosis. It is important for the nurse to communicate effectively with the parents and allow them to fully express their feelings and concerns. In addition to the information provided by the parents, the nurse will conduct a full physical assessment to determine if the child is exhibiting symptoms consistent with MD or a similar disorder. Cues that would indicate the child may have MD include an abnormal gait, muscle weakness, contractures, and an inability to stand from a sitting position.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Most of the nursing interventions for patients with MD center around maintaining muscle function and slowing the progression of the disorder. These interventions include

- assisting with ADLs as needed,
- promoting as much independence as possible,
- helping with range of motion (ROM) exercises,
- alternating rest and activity periods to combat fatigue and muscle weakness,
- teaching deep breathing and relaxation techniques,
- implementing fall-risk precautions as needed,
- providing emotional support and teaching patient positive coping skills, and
- coordinating care with other members of the health-care team, including physical and occupational therapists.

Evaluation of Nursing Care for the Patient with Muscular Dystrophy

Though MD is progressive, medical and nursing interventions can help slow the trajectory of the disorder. The nurse will need to evaluate the interventions to determine if the plan of care should be revised to ensure optimal patient outcomes.

Evaluating Outcomes

When evaluating outcomes for the patient with MD, the nurse will look for specific findings indicating the interventions have been successful. These findings include

- improved muscle strength,
- normal cardiac rhythm,

- adequate oxygenation status, and
- positive coping skills.

Medical Therapies and Related Care

There is no cure for MD, but some treatments may help with symptom relief. In many cases, long-term corticosteroids are used to help maintain muscle strength for as long as possible. However, the side effects of steroids include weight gain, weakened bones, and a decrease in immune function, all of which can be detrimental to the health of the patient. In these cases, the benefits of using long-term steroids must be weighed against the risks.

In recent years, several new medications have been developed specifically for the treatment of MD. One of these medications, eteplirsen (Exondys 51), works by targeting the specific genetic mutations that cause MD. In addition to these medications, patients with MD who have experienced heart damage may also require treatment with cardiac medications such as angiotensin-converting enzyme inhibitors (ACEIs) or beta blockers. Beyond pharmacological interventions, patients with MD also require therapy to prolong muscle function for as long as possible. Therapy interventions to prolong muscle function include

- physical and occupational therapy,
- ROM exercises,
- low-impact aerobic exercise (e.g., swimming, walking),
- braces, and
- mobility aids (e.g., canes, walkers, wheelchairs).

For patients with cardiac or respiratory issues secondary to MD, use of a ventilator or insertion of a pacemaker may eventually be required.

INTERDISCIPLINARY PLAN OF CARE

Interdisciplinary Care for Patients with MD

Nurses work with an interdisciplinary team and coordinate care for patients with MD.

- The provider orders the treatment plan, including medications and any specialty referrals needed to manage the patient's care.
- The nurse implements the provider's orders and educates the patient about their condition.
- The respiratory therapist provides set-up, maintenance, and instructions for any pulmonary machines, such as a sleep apnea or ventilator; they also educate the patient on pulmonary exercises, such as incentive spirometer, and breathing treatments.
- The case manager coordinates ancillary departments needed for a comprehensive plan of care, such as wound care or nutrition; they also coordinate resources and follow-up for the family once the patient is discharged.

13.5 Connective Tissue Disease

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for connective tissue disease
- Describe the diagnostics and laboratory values of connective tissue disease
- Apply nursing concepts and plan associated nursing care for patients with connective tissue disease
- Evaluate the efficacy of nursing care for patients with connective tissue disease
- Describe the medical therapies that apply to the care of connective tissue disease

Connective tissue, as its name implies, binds the cells and organs of the body together and functions in the protection, support, and integration of all parts of the body. Connective tissue performs many functions in the body; most importantly, it supports and connects other tissues. It is found in many places in the body, from the connective tissue sheath that surrounds muscle cells, to the tendons that attach muscles to bones, to the skeleton that

supports the positions of the body. Protection is another major function of connective tissue, in the form of fibrous capsules and bones that protect delicate organs. Specialized cells in connective tissue defend the body from microorganisms that enter the body. Transport of fluid, nutrients, waste, and chemical messengers is ensured by specialized fluid connective tissues, such as blood and lymph.

There are several disorders that affect connective tissues. In an **autoimmune** disorder, the body's immune system mistakenly attacks healthy cells. Two autoimmune disorders involving connective tissue, systemic lupus erythematosus and rheumatoid arthritis, are discussed in more detail in this section.

Systemic Lupus Erythematosus

The most common form of lupus, **systemic lupus erythematosus (SLE)** is an autoimmune disorder that results in widespread inflammation and tissue damage. Currently, about 1.5 million Americans have some type of lupus, with 70 percent of cases classified as SLE (Lupus Foundation of America, 2016). This disorder is most often diagnosed in female patients during their childbearing years, but it can affect anyone regardless of age or sex. Lupus is two to three times more common in underrepresented racial and ethnic groups, including Hispanic and Asian/Pacific Islander populations (Hasan et al., 2022).

Pathophysiology

The underlying pathophysiology of SLE is not well understood, but it has been shown to have an autoimmune cause. Specifically, the body develops antibodies that attack healthy body cells. Additionally, the body forms many antigen-antibody complexes that can get stuck in capillaries, resulting in **vasculitis**, or inflammation of the blood vessels, and eventual tissue damage. In addition to autoimmune causes, several environmental factors increase the risk for developing SLE, including:

- exposure to ultraviolet (UV) radiation,
- viral infections,
- cigarette smoking, and
- emotional or physical stress.

LIFE-STAGE CONTEXT

SLE and Pregnancy

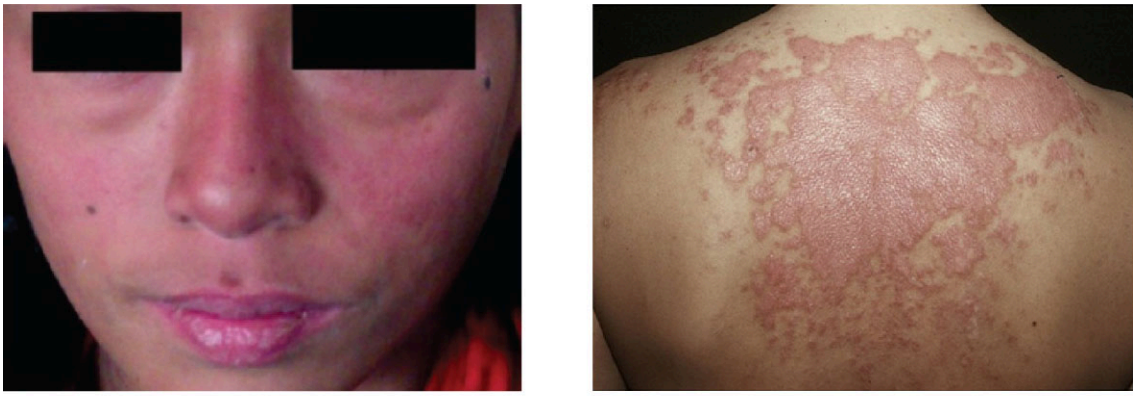
Patients diagnosed with SLE are often of childbearing age, which can cause severe anxiety and stress about their chances of having a healthy pregnancy and childbirth. Patients with SLE who become pregnant often require more intensive monitoring throughout the pregnancy to ensure the safety of both patient and child. Many of the medications prescribed for SLE are not safe during pregnancy, so it is important for the patient to maintain frequent communication with their primary care provider and obstetrician to find a suitable treatment plan.

Clinical Manifestations

The organs most-commonly damaged by SLE include the skin, joints, heart, lungs, kidneys, and brain, so most clinical manifestations will involve these body systems. Additionally, most cases of SLE involve alternating periods of illness ("flares") and improvement in symptoms ("remissions"). Common clinical manifestations of SLE include

- joint pain and swelling;
- fever;
- fatigue;
- cognitive impairment and neurological manifestations (e.g., headaches, personality changes, ischemic stroke, seizures);
- abnormal hair loss, or **alopecia**;
- mouth sores;
- "butterfly" rash on the face or "discoid" rash, usually on the face or trunk (Figure 13.16);
- inflammation of the nephrons of the kidneys, or **nephritis**, which causes renal damage and may lead to the development of hypertension;
- inflammation of the pleural tissue around the lungs, or **pleuritis**, which causes chest pain and pain with

respiration;
- inflammation of the pericardial sac around the heart, or **pericarditis**, which causes substernal chest pain;
- **Raynaud's syndrome**, a condition that occurs when the fingers become pale when exposed to cold or stress states;
- enlargement of the spleen, or **splenomegaly**; and
- swelling of the lymph nodes, or **lymphadenopathy**.



(a) (b)

FIGURE 13.16 (a) Butterfly rash across the nose and cheeks and (b) discoid rash on the back are commonly associated with SLE. (credit: (a) "Butterfly rash of lupus erythematosus" by Mikael Haggström/Wikimedia Commons, CC BY 4.0); (b) "Subacute cutaneous lupus erythematosus" by Uva et al./*Autoimmune Diseases*, CC BY 3.0)

Assessment and Diagnostics

Several conditions have similar clinical manifestations to SLE, so if any symptoms of SLE are assessed, further diagnostic and laboratory testing is warranted to rule out the other potential diagnoses. Many health-care providers and facilities use a standardized diagnostic tool to assess symptoms and laboratory values associated with SLE and assist in making a definitive diagnosis. One of these tools is the EULAR/ACR criteria.

LINK TO LEARNING

This table lists the EULAR/ACR Criteria (https://openstax.org/r/77EULAR_ACR) for classifying systemic lupus erythematosus (SLE).

Diagnostics and Laboratory Values

The most specific diagnostic test for SLE is the antinuclear antibody (ANA) test. This blood test looks for autoantibodies. An **autoantibody** is an antibody that attacks its own body cells; they are commonly associated with SLE. Though the presence of these autoantibodies does not always indicate SLE, they are present in most cases, so a positive test indicates the need for further diagnostic workup (LaPelusa et al., 2024). Though not specific to lupus, a complete blood count (CBC) is also indicated during the diagnostic process for SLE. Certain findings from the CBC, such as leukopenia and thrombocytopenia, may help confirm the diagnosis of SLE.

Nursing Care of the Patient with Systemic Lupus Erythematosus

The main goals of nursing care for patients with SLE are to manage symptoms, prevent or limit the effects of disease flares, and improve the patient's overall quality of life. Additionally, the nurse will often need to provide mental and emotional support for the patient because SLE can negatively affect many different aspects of the patient's life.

Recognizing Cues and Analyzing Cues

The nurse must remain attentive for clinical signs indicating the patient with SLE may be experiencing a disease flare. Most often, this is exhibited with changes in the skin, such as butterfly rash across the face, discoid rash on the trunk, or Raynaud's syndrome in the fingers. It is also important for the nurse to obtain a thorough subjective report of symptoms from the patient, as they may experience fatigue, joint pain, or hair loss as part of a flare. The nurse should immediately report any significant symptoms indicating a flare so the provider can initiate treatment, thereby slowing the progression of the disease and preventing organ and tissue damage.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

One of the main nursing interventions for patients with SLE is the administration of medications to treat symptoms. These include NSAIDs, corticosteroids, immunosuppressants, and biologic medications. The nurse will also provide the patient with extensive education about the prescribed medications. Most of the medications prescribed for SLE have negative side effects; the nurse must teach the patient about these side effects while still stressing the importance of taking the medications as prescribed. Because SLE is a lifelong condition, the nurse will also provide education about the importance of maintaining regular follow-up appointments and self-monitoring for symptoms of disease flares.

Evaluation of Nursing Care for the Patient with Systemic Lupus Erythematosus

Because there is no cure for SLE, it is important that the nurse, provider, and patient maintain frequent communication about the patient's health status to determine the effectiveness of the plan of care. In some cases, the medications prescribed for SLE may no longer be effective, warranting the need for changes to the type, dose, or frequency of the drug or for more-intensive treatment options.

Evaluating Outcomes

When evaluating a patient with SLE to determine the effectiveness of their plan of care, the nurse should assess for signs indicating the treatment interventions are working. These signs include

- less-frequent disease flares or fewer severe symptoms during flares,
- improved skin appearance,
- less (or no) joint pain,
- hair regrowth, and
- normal kidney function, as evidenced by normal serum creatinine and blood urea nitrogen (BUN) levels.

Medical Therapies and Related Care

There is currently no cure for SLE, but there are several supportive treatments for symptoms that will assist in improving the patient's quality of life. First and foremost, anti-inflammatory medications such as NSAIDs are used to help reduce associated pain, fever, and inflammation. Corticosteroids are also often prescribed to limit inflammation associated with SLE. These can be prescribed orally but may also be administered as a topical cream to directly treat rashes or other skin conditions that occur with SLE. Because SLE is an autoimmune disorder, immunosuppressant medications may also be prescribed. These medications work by suppressing the patient's immune system to keep it from attacking its own healthy body cells. Lastly, B-lymphocyte stimulator (BlyS) protein inhibitor is often used to decrease the lifespan of abnormal antibodies, helping to prevent the autoimmune attacks that occur with the condition. In some cases, medications lose their effectiveness and organ damage becomes too severe; when this happens, organ transplantation—most often involving the kidneys—may be necessary.

Rheumatoid Arthritis

The autoimmune disorder that causes inflammation of the synovial joints in the body is called **rheumatoid arthritis (RA)**. This condition affects about 1 percent of the global population, including about 1.3 million American adults—a significant number, considering this disorder is a major cause of work disability and can substantially impact overall quality of life (Xu & Wu, 2021). Though RA can affect both sexes, it is two times more prevalent in females than in males (Chauhan et al., 2023).

Pathophysiology

RA is a chronic inflammatory disease of the joints. It is thought to be genetic in nature. Certain genetic mutations predispose individuals to developing this condition, and these mutations can be passed from generation to generation. In an individual with genetic mutations that put them at risk for developing RA, certain environmental triggers such as cigarette smoking or asbestos exposure can result in the development of the disorder. The environmental trigger starts the process of the body making autoantibodies that begin to attack and destroy the body's joints, causing widespread inflammation.

Clinical Manifestations

This condition can affect all the joints in the body, but the most-commonly affected joints are in the hands. Clinical manifestations associated with RA include

- joint pain and swelling,
- joint stiffness that is typically worse in the morning,
- limited range of motion, and
- rheumatoid nodules (Figure 13.17).

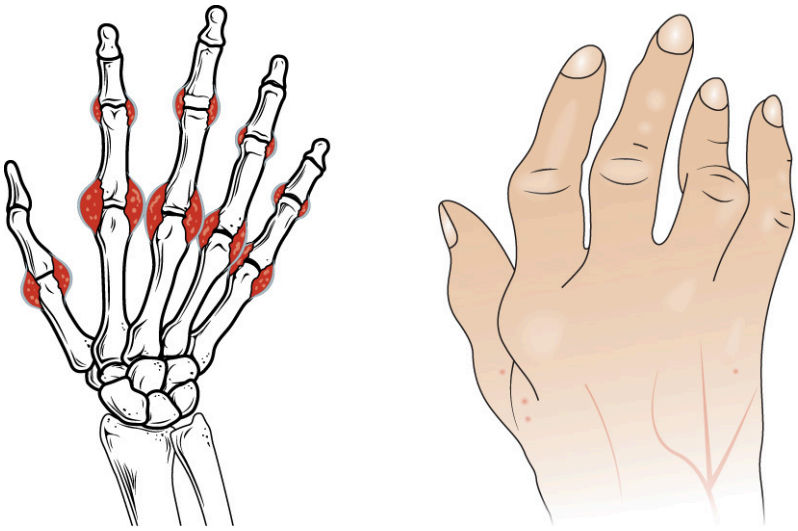


FIGURE 13.17 Nodules can form on the knuckle joints of the hands in rheumatoid arthritis. (credit: modification of work from *Anatomy and Physiology*, 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Assessment and Diagnostics

During the physical assessment, the nurse should first ask the patient about their symptoms, including any joint pain, swelling, or stiffness, and confirm that these symptoms are more severe upon waking in the morning. After gathering a history of the patient's symptoms, the nurse should perform a visual inspection of the hands and feet to look for the presence of RA nodules. As part of the physical assessment, the nurse should check the patient's range of motion and determine whether it is limited in any joints. Bilateral grip strength should also be assessed to see if the arthritis has diminished the patient's ability to use their hands effectively. During palpation of the joint, the nurse will note any areas that feel "boggy," which may indicate the presence of RA.

Diagnostics and Laboratory Values

A few different laboratory tests can assist in diagnosing RA. First, a blood sample can be taken to determine the presence or absence of rheumatoid factor (RF), which is an antibody found in nearly 90 percent of patients with RA (Chauhan et al., 2023). Additionally, the blood can be tested for erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), both of which indicate elevated systemic inflammation. In addition to blood tests, imaging such as x-ray, ultrasound, or MRI may be used to look for bone erosion associated with RA. However, it is important to note that imaging tests will not show bone damage until the disorder has progressed significantly, so a normal imaging test does not rule out RA.

Nursing Care of the Patient with Rheumatoid Arthritis

Unfortunately, there is no cure for RA. The main goals of nursing care are to manage symptoms, limit damage to joint tissue, and improve overall quality of life.

Recognizing Cues and Analyzing Cues

First and foremost, it is important for the nurse to conduct a thorough physical examination to assess for joint pain or swelling and other symptoms that may indicate the presence of RA. The main cue that the nurse should assess for is the hallmark sign of RA: joint pain and stiffness that are worse in the morning.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

After analyzing the aforementioned cues, the nurse may hypothesize that the patient has RA. One of the main nursing interventions for patients with RA involves the administration of disease-modifying antirheumatic drugs (DMARDs), nonsteroidal anti-inflammatory drugs (NSAIDs), and corticosteroids. The nurse will work with the provider and patient to determine an effective dose and tapering plan and provide counseling about the negative side effects associated with long-term use of corticosteroids (e.g., weight gain, infections). A tapering plan for

corticosteroids is important to prevent adrenal insufficiency, which can result in severe fatigue and other side effects. Other nursing interventions to promote patient comfort include the application of cold and heat, the initiation of physical therapy and other exercises as tolerated, and alternating rest and activity periods to limit stress on the joints.

Evaluation of Nursing Care for the Patient with Rheumatoid Arthritis

It is important for the nurse, provider, and patient to maintain frequent communication about the patient's health status to determine the effectiveness of their treatment plan and disease management. Each nursing intervention will be evaluated for effectiveness or the need for revision.

Evaluating Outcomes

When evaluating a patient with RA to determine the effectiveness of their plan of care, the nurse should assess for signs indicating the treatment interventions are working. These signs include

- improved range of motion,
- decreased joint pain, swelling, and stiffness,
- improved grip strength, and
- lack of reported side effects of medications.

Medical Therapies and Related Care

The main pharmacological treatments for RA involve DMARDs, NSAIDs, or corticosteroids. DMARDs are the only kind of medication that act to slow the progression of the disease; they interfere with inflammatory pathways that cause disease symptoms. The main concern associated with this class of medications is that it greatly increases the patient's risk for developing infections. NSAIDs are used to treat the pain and inflammation associated with RA, but they have no effect on the progression of the disease. Corticosteroids are used to reduce the inflammation associated with disease flareups; long-term use should be avoided when possible, as their side effects include weight gain, osteoporosis, and increased risk of infection.

13.6 Soft Tissue Injuries

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for soft tissue injuries
- Describe the diagnostics and laboratory values associated with soft tissue injuries
- Apply nursing concepts and plan associated nursing care for patients with soft tissue injuries
- Evaluate the efficacy of nursing care for patients with soft tissue injuries
- Describe the medical therapies that apply to the care of soft tissue injuries

Soft tissue injuries affect multiple parts of the body, including muscles, tendons, and ligaments. These types of injuries are common because they occur by many different mechanisms, including athletics, trauma, falls, and normal aging. There are several different types of soft tissue injuries, including sprains, strains, contusions, tendinitis, and bursitis (Table 13.6).

Type of Injury	Description	Areas Commonly Affected
Sprain	Overstretching or tearing of a ligament	• Ankles • Knees • Wrists
Strain	Overstretching or tearing of a muscle or tendon	• Back • Leg (most often the hamstring)

TABLE 13.6 Common Soft Tissue Injuries

Type of Injury	Description	Areas Commonly Affected
Contusions (bruises)	Direct blow(s) to a body part (often with a blunt object), causing damage to underlying muscle and tissue without breaking the skin	• Any part of the body that is hit with the object
Tendinitis	Inflammation or irritation of a tendon from overuse	• Shoulders • Elbows • Feet • Knees • Ankles
Bursitis	Inflammation of a bursa, producing small, fluid-filled sacs (often co-occurs with tendinitis)	• Shoulders • Elbows • Hips • Knees • Heels

TABLE 13.6 Common Soft Tissue Injuries

Pathophysiology

The underlying pathophysiology of soft tissue injuries varies depending on the specific type of injury. Strains and sprains are most often the result of playing sports, as movements such as twisting, turning, and pulling may stretch or tear muscles, ligaments, or tendons. Bruising, or **contusion**, typically occurs from direct blows to the body, such as those obtained from falling or while playing contact sports. The overuse of a tendon causes **tendinitis**, inflammation of a tendon, so this injury is commonly seen in athletes who repeatedly use the same muscles and tendons: for example, tennis players swinging a racquet or baseball pitchers throwing a ball. Usually, a co-occurring condition with tendinitis is bursitis. As the overused tendon becomes inflamed, fluid builds up in the neighboring bursa, resulting in **bursitis**, which is inflammation of the bursa.

Clinical Manifestations

Clinical manifestations of soft tissue injuries vary depending on the area of the body affected and the type of injury that occurred. Some of the most common clinical manifestations associated with soft tissue injuries include

- swelling,
- redness or bruising on the skin,
- pain,
- muscle spasms, and
- muscle weakness.

Assessment and Diagnostics

Most often, physical assessment of the affected part of the body is enough to confirm a diagnosis of a soft tissue injury. For injuries that are less obvious upon visual inspection, imaging studies such as CT or MRI may be indicated. X-rays may be used if bone damage is suspected, but they do not show soft tissue injury as well as other imaging modalities do. There are no specific diagnostic tests that are used to confirm soft tissue injury. In some cases, such as traumas or falls, tests such as hemoglobin and hematocrit may be indicated to monitor for blood loss.

Nursing Care of the Patient with Soft Tissue Injuries

The main goals of nursing care for patients with soft tissue injuries are to manage symptoms and heal the affected part of the body. Patient education is a large component of nursing care for these patients to assist in the healing of the affected muscle, tendon, or ligament.

Recognizing Cues and Analyzing Cues

The nurse must remain attentive for clinical signs indicating the patient is experiencing a soft tissue injury. Most often, the patient will present with pain and swelling of the affected area and report having recently participated in an athletic event or experienced a fall or other trauma. With these cues present, the nurse will hypothesize that the patient has experienced some kind of soft tissue injury; the nurse can then ask more specific questions to determine which kind of injury they have. For example, if a patient experiencing shoulder pain reports they are an avid tennis player, the nurse may hypothesize that they have tendinitis in the shoulder from overuse.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

One of the main nursing interventions for patients with soft tissue injuries is using the "RICE" acronym, which stands for rest, ice, compression, and elevation. The nurse will encourage the patient to take a break from the activity that caused the injury and apply ice packs for 20 minutes at a time several times per day. Additionally, the nurse should apply a compression bandage to limit swelling and elevate the affected injury higher than the level of the patient's heart to reduce swelling and promote circulation to the joint. For sprains, the patient may require application of a brace to stabilize the joint. The nurse should assist the patient in applying the brace for the first time and make sure the patient is able to do it themselves upon discharge home.

Evaluation of Nursing Care for the Patient with Soft Tissue Injuries

Most types of soft tissue injuries are self-limiting, meaning they will improve over time on their own. To ensure the injury is improving, the nurse should schedule a follow-up appointment after discharge. In some severe cases where improvement is not seen at the follow-up appointment, surgery or other intervention may be required, but typically using RICE is enough to produce significant improvement.

Evaluating Outcomes

When evaluating a patient with a soft tissue injury to determine the effectiveness of their plan of care, the nurse should assess for signs indicating that the treatment interventions are working. These signs include

- decreased swelling,
- less self-reported pain,
- improved bruising, and
- improved range of motion.

Medical Therapies and Related Care

In addition to RICE, treatment for soft issue injuries often involves the administration of NSAIDs, which aim to help reduce swelling and pain. In more severe cases of pain, opioid medications may be prescribed, but this is not common. Most importantly, the patient should be educated on strategies to prevent these kinds of injuries in the future. Prevention strategies include

- using proper equipment (e.g., weights, shoes, other sports equipment),
- warming up before participating in physical activity,
- staying hydrated,
- cooling down after physical activity,
- stretching before and after physical activity, and
- resting during physical activity as needed.

Summary

13.1 Osteoporosis and Osteopenia

Osteoporosis is a bone disease in which a person's bone mineral density and bone mass decreases, causing changes to the quality or structure of the bone. Osteopenia, a decrease in bone mineral density, is the precursor condition to osteoporosis.

The underlying pathophysiology of osteoporosis involves too much resorption of small amounts of minerals from the bone over time. Common clinical manifestations of osteoporosis include bone fractures, back pain, kyphosis, and a loss of total height over several years. The gold standard diagnostic test for osteopenia and osteoporosis is the dual-energy x-ray absorptiometry (DEXA or DXA) scan, which uses low-dose radiation x-rays to determine bone density of the hip, wrist, or spine. Treatment options for osteoporosis involve a combination of modifying lifestyle risk factors and prescribing pharmacological interventions.

13.2 Osteoarthritis

OA is a degenerative joint disorder that causes the cartilage to gradually become thinner. As the cartilage layer wears down, more pressure is placed on the bones, causing pain. Common clinical manifestations of OA include joint pain and swelling, limited range of motion, muscle weakness, and "grating" sensations with joint movement. Diagnostic tests for OA include physical examination and assessment, imaging, arthrocentesis, and serum inflammatory markers. Treatment for OA includes both pharmacological interventions (e.g., NSAIDs, analgesics) and nonpharmacological interventions (e.g., exercise, assistive devices).

13.3 Bone Fractures

Fractures, or breaks in the bone structure, are one of the most common types of musculoskeletal traumas. When a bone fracture occurs, the soft tissue surrounding the bone is also usually affected, potentially resulting in soft tissue injuries such as edema, hemorrhage, tendon damage, or severed nerves. The specific clinical manifestations of fractures will vary depending on the anatomic location affected, but they usually include pain, edema, inability to move the affected part, bruising, and extremity deformities. The only definitive way to diagnose a bone fracture is to visualize the break in the bone structure, which can be done with imaging studies including x-ray, CT scan, and MRI. In some cases, the fracture will heal on its own; in other cases, more invasive interventions such as immobilization, reduction, fixation, or surgery may be required.

13.4 Muscular Dystrophy

Muscular dystrophy (MD) is a rare genetic disorder that causes progressive muscle weakness over time; over 30 specific types exist. The underlying pathophysiology of MD is caused by genetic mutations, either inherited or spontaneous. Clinical manifestations of MD vary depending on the specific type, but common findings include muscle weakness and atrophy, contractures, and frequent falls or clumsiness. Because most MDs are diagnosed in childhood, it is often the child's parents who notice the first signs that may indicate a muscular problem. Treatment for MD involves a combination of pharmacological interventions (e.g., long-term corticosteroids) and nonpharmacological interventions (e.g., physical and occupational therapies).

13.5 Connective Tissue Disease

Systemic lupus erythematosus (SLE) is the most common form of lupus, an autoimmune disorder that results in widespread information and tissue damage. The organs most-commonly damaged by SLE include the skin, joints, heart, lungs, kidneys, and brain, so most clinical manifestations will involve these body systems. The most specific diagnostic test for SLE is the antinuclear antibody (ANA) test, which looks for autoantibodies commonly associated with lupus. The main goals of nursing care for patients with SLE are to manage symptoms, prevent or limit the effects of disease flares, and improve the patient's overall quality of life. Treatment for SLE includes the use of anti-inflammatory medications such as NSAIDs and corticosteroids, as well as immunosuppressants and biologic medications.

Rheumatoid arthritis (RA) is an autoimmune disorder that causes inflammation of the synovial joints in the body. RA can affect all the joints in the body, but it most-commonly affects the joints in the hands. Symptoms include joint pain, swelling, and stiffness that is worse in the morning. Diagnostic tests for RA include rheumatoid factor (RF),

erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP), in addition to imaging such as x-ray, ultrasound, or MRI. Pharmacologic treatment for RA includes use of disease-modifying antirheumatic drugs (DMARDs), nonsteroidal anti-inflammatory drugs (NSAIDs), and corticosteroids.

13.6 Soft Tissue Injuries

There are several different types of soft tissue injuries, including sprains, strains, contusions, tendinitis, and bursitis. The most common clinical manifestations associated with soft tissue injuries include swelling, redness, pain, muscle weakness, and spasms. Most often, physical assessment of the affected part of the body is enough to confirm a diagnosis of a soft tissue injury. For injuries that are less obvious upon visual inspection, imaging studies such as CT or MRI may be indicated. The main goals of nursing care for patients with soft tissue injuries are to manage symptoms and heal the affected part of the body. One of the main nursing interventions for patients with soft tissue injuries is using the "RICE" acronym, which stands for rest, ice, compression, and elevation.

Key Terms

alopecia abnormal hair loss
arthrocentesis joint aspiration
arthroplasty joint replacement
autoantibody antibody that attacks its own body cells
autoimmune disorder condition in which the body's immune system mistakenly attacks healthy cells
bone spur bony projection that develops along bone edges
bursitis inflammation of the bursa
compartment syndrome condition caused by increased pressure within an area of tissue and resulting in muscle and nerve damage
contusion bruising
dystrophin protein involved in maintaining muscle strength and function
external fixation internal placement of screws on either side of a fracture by drilling pins into the bone and then connecting them to an external brace or bracket
fasciotomy incision into the skin and fascia to relieve pressure
fracture break in bone structure
internal fixation placement of metal pieces into the bone to help it heal as it grows back together
kyphosis excessive curvature of the upper spine
lymphadenopathy swelling of the lymph nodes
mobility ability of a patient to change and control their body position
muscular dystrophy (MD) rare genetic disorder that causes progressive muscle weakness over time
nephritis inflammation of the nephrons of the kidneys
osteoarthritis (OA) degenerative joint disease disorder that involves the wearing down of joint cartilage and tissue over time
osteoclast cell that breaks down bones
osteopenia decrease in bone mineral density
osteoporosis bone disease caused by a significant decrease in bone density and mass
pericarditis inflammation of the pericardial sac around the heart
pleuritis inflammation of the pleural tissue around the lungs
Raynaud's syndrome condition that occurs when the fingers become pale when exposed to cold or stress states
resorption breakdown and reabsorption over time of small amounts of minerals from the bone
rheumatoid arthritis (RA) autoimmune disorder that causes inflammation of the synovial joints in the body
scoliosis abnormally curved spine
splenomegaly enlargement of the spleen
systemic lupus erythematosus (SLE) autoimmune disorder that results in widespread inflammation and tissue damage
tendinitis inflammation of a tendon from overuse
vasculitis inflammation of the blood vessels

Assessments

Review Questions

1. The nurse is caring for a patient who is concerned about developing osteoporosis. What risk factor for osteoporosis should the nurse mention to the patient?
    a. male sex
    b. high body mass index
    c. regular exercise
    d. postmenopausal status

2. What assessment finding should the nurse anticipate when assessing a patient diagnosed with osteoporosis?
    a. scoliosis
    b. headache
    c. lower-back pain
    d. tachycardia

3. The nurse is reviewing medications with a nursing student before administering them to a patient. When asked about alendronate, a bisphosphonate, what statement by the nursing student indicates an understanding of how this medication treats osteoporosis?
    a. “This medication acts as a calcium supplement.”
    b. “Alendronate inhibits cells that break down my bones.”
    c. “This drug mimics effects of estrogen to protect my bones.”
    d. “This medication works by increasing bone marrow density.”

4. What factor increases the risk for developing osteoarthritis (OA)?
    a. male sex
    b. adolescent age
    c. underweight status
    d. overuse of finger joints

5. The nurse is caring for a patient who presents to the clinic and reports swelling and pain in their fingers over the last few months, which is worse in the mornings. What diagnostic test would the nurse anticipate being ordered?
    a. CT scan
    b. urinalysis
    c. lumbar puncture
    d. C-reactive protein

6. Nursing care of a patient with osteoarthritis should include what action?
    a. limit range of motion (ROM)
    b. promote dependence for ADLs
    c. implement comfort measures
    d. use opioids for pain control

7. What type of fracture results in the formation of several small bone fragments?
    a. spiral
    b. oblique
    c. greenstick
    d. comminuted

8. What terms are included in the 5 P’s of neurovascular assessments? Select all that apply.
    a. pain
    b. position

c. paresthesia
d. pregnancy
e. pallor

9. What treatment option for bone fractures involves the insertion of screws that are attached to a metal brace outside the body?
a. immobilization
b. closed reduction
c. internal fixation
d. external fixation

10. After removal of a cast, what finding does the nurse recognize to indicate that the treatment was effective?
a. increased pain
b. no visible bone deformities
c. skin pallor
d. strong pulses proximal to the fracture

11. What is the most common cause of muscular dystrophy (MD)?
a. viral infections
b. genetic mutations
c. immunosuppression
d. childhood cancers

12. What type of MD results in an inability to relax the muscles after contraction?
a. myotonic dystrophy
b. Duchenne muscular dystrophy
c. limb-girdle muscular dystrophy
d. facioscapulohumeral muscular dystrophy

13. What is the main function of connective tissue?
a. neurological regulation
b. protection of internal organs
c. cardiovascular support
d. bone formation

14. What factor increases the risk of developing SLE?
a. bacterial infections
b. history of cancer
c. exposure to UV radiation
d. vasculitis

15. What is the priority diagnostic test for SLE?
a. hemoglobin
b. white blood cell count
c. antinuclear antibody
d. muscle biopsy

16. The nurse is collecting a medical history from a patient who presents with new-onset joint stiffness and swelling. The nurse suspects RA. What information, if provided in the patient's medical history, would help confirm this diagnosis?
a. history of breast cancer
b. occupational exposure to asbestos
c. previous exposure to Epstein-Barr virus

d. history of systemic lupus erythematosus (SLE)

17. The nurse is reviewing lab results for a patient being worked up for RA. What abnormal lab finding would be most consistent with a diagnosis of RA?
a. decreased C-reactive protein (CRP)
b. elevated erythrocyte sedimentation rate (ESR)
c. decreased red blood cell count
d. elevated hemoglobin and hematocrit

18. What medical therapy is priority for treating SLE?
a. NSAIDs
b. corticosteroids
c. immunosuppressants
d. B-lymphocyte stimulator (BlyS) protein

19. The nurse is caring for a patient who has presented to the emergency room after a soccer game and reported a sore ankle. What condition does the nurse suspect is most likely?
a. sprain
b. contusion
c. bursitis
d. tendinitis

20. The nurse is caring for a patient admitted for a back muscle strain. What medication does the nurse anticipate is most likely to be ordered for the patient?
a. penicillin
b. ibuprofen
c. oxycodone
d. azithromycin

21. Due to the self-limiting nature of soft tissue injuries, how can the nurse evaluate efficacy of home therapies like RICE?
a. Assume the patient is better if they do not call back.
b. Ensure follow-up appointments are scheduled.
c. Connect the patient with a home care nurse.
d. Call the patient daily to monitor symptoms.

Check Your Understanding Questions

1. What components of the Fracture Risk Assessment (FRAX) Tool indicate that a patient is at higher risk for experiencing a fracture related to osteoporosis?

2. What assessment findings would indicate that interventions have been effective for a patient being treated for osteoarthritis?

3. What lifestyle modifications would you suggest to a patient with osteoarthritis?

4. What assessment findings would cause you to worry about the development of common complications after a bone fracture?

5. What clinical manifestations would the nurse anticipate being reported by the parents of a child with suspected MD?

6. What diagnostic tests would you anticipate being ordered for a patient with suspected MD?

7. What clinical manifestations would display to the nurse the efficacy of nursing care for a patient with MD?

8. What assessment findings would you anticipate in a patient who presents with SLE?

9. The nurse is providing discharge education to a patient newly diagnosed with RA. The patient has been prescribed a course of corticosteroids. What information should the nurse include in the teaching?
10. The nurse plans to revise the plan of care for a patient with RA based upon their evaluation findings. What clinical findings might the nurse see in the evaluation that prompt this revision?
11. What assessments will the nurse perform on a patient with a suspected soft tissue injury?
12. What education is important for the nurse to provide to a patient upon discharge after being treated for a sprained ankle?

Reflection Questions

1. What assessment findings would indicate that a patient with osteoporosis is benefiting from their treatment plan?
2. What is the significance of females having a higher prevalence of osteopenia than males?
3. What is the most definitive diagnostic for MD?
4. How would you handle a conversation with a young female patient with SLE who is concerned about the chances of having a healthy pregnancy?
5. What joints are commonly affected with tendonitis, and what are the likely causes?

What Should the Nurse Do?

You are caring for a 27-year-old male patient who presents to the emergency room after a fall during a soccer game. The patient reports that they cannot move their ankle, which has been becoming progressively more swollen in the last hour since the fall. Upon assessment, you notice that the patient's foot is turning purple and the patient is losing the ability to wiggle their toes on command.

1. What kind of injury do you suspect the patient has?
2. What kind of diagnostic test do you anticipate for the patient?
3. Based on the assessment findings, are you concerned about anything at this point?

The nurse is caring for a 2-year-old patient who is brought to the clinic by their parents for frequent falls at home. After assessing the patient and running diagnostic tests, the patient is diagnosed with Duchenne muscular dystrophy (DMD).

4. What other clinical manifestations would you warn the parents that the child may experience over the course of their life?
5. What resources would you provide to the parents to assist them with their child's new diagnosis?
6. The parents fear that since the disease cannot be cured, their child will suffer. What can you mention as possible treatments?

The nurse is caring for a 32-year-old female patient recently diagnosed with SLE.

7. What treatments would the nurse anticipate being ordered for the patient?
8. What considerations and side effects of the treatment options should the nurse discuss with the patient?

Competency-Based Assessments

1. Create a care plan for a patient with osteoporosis. The care plan should include at least three specific nursing interventions and expected outcomes.
2. Develop a chart outlining the diagnostics used to diagnosis and monitor treatment of osteoarthritis.
3. Develop a presentation outlining and describing the medical therapies for a patient with a long bone fracture.
4. Develop a brief presentation outlining interventions a patient can do in their home to reduce RA flare-ups.
5. Develop a flyer with the acronym commonly used as a nursing intervention for the treatment plan of a soft tissue injury.

CHAPTER 14
Integumentary System

FIGURE 14.1 Dermatological conditions often produce symptoms of itching and rashes. (credit: modification of "Woman Scratching Skin" by NIAID/Flickr, CC BY 2.0)

CHAPTER OUTLINE

INTRODUCTION A nurse is admitting a patient with an unknown skin condition for further evaluation by the health-care provider. The patient's skin is red and flaking. What are the nurse's next steps when gathering pertinent information on this patient? When completing the physical assessment, what other information might the nurse need to assist the health-care provider with this patient's diagnosis? Once the cause and diagnosis are determined, what nursing interventions would the nurse implement for this patient? This chapter reviews common dermatological conditions encountered in the health-care setting. After reading this chapter, you will better understand how to recognize and analyze cues of a patient's integumentary conditions. Also, you will be able to determine a priority nursing diagnoses, create a nursing care plan, generate nursing interventions, and expected outcomes related to your interventions.

14.1 Integumentary Disorders

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations of atopic dermatitis and eczema
- Describe the diagnostic and laboratory values related to specific diseases of the integumentary system
- Apply nursing concepts and plan associated nursing care for the patient with various integumentary disorders
- Evaluate the efficacy of nursing care for patients with integumentary disorders
- Describe the medical therapies that apply to treating various integumentary disorders

The **integumentary system** is the body's largest organ. It comprises the skin, hair, nails, and integumentary (exocrine) glands. The **exocrine glands** secrete their substances through ducts onto the skin's epithelial surface, whereas endocrine glands release their substances directly into the bloodstream. Some examples of the skin's exocrine glands are sweat glands and sebaceous glands, which produce **sebum**, the oil that keeps the skin moisturized. More information about endocrine glands can be found in Chapter 21 Endocrine System and Endocrine System Disorders.

The main function of the integumentary system is to protect the body from outside organisms such as bacteria and viruses. It also helps regulate the body's temperature (MedlinePlus, 2023). Integumentary conditions may also be called dermatological conditions, given the layers of the skin being discussed. Nurses and health-care professionals encounter various dermatological conditions throughout their careers, and some conditions are more common than others. It is important to understand the causes behind these conditions, their clinical manifestations, and relevant nursing interventions.

Integumentary Anatomy Overview

The skin comprises three layers: the epidermis, the dermis, and the hypodermis (Figure 14.2). The **epidermis** is the outermost layer, made of epithelial cells, and is the body's first defense against organisms. The **dermis** is the middle layer, just below the epidermis, and is made up of connective tissue that supports the epidermis. Lastly, the **hypodermis**, commonly referred to as the subcutaneous tissue, is the bottom layer that is made of adipose and areolar tissue that cushions the underlying organs (Kim and Dao, 2023).

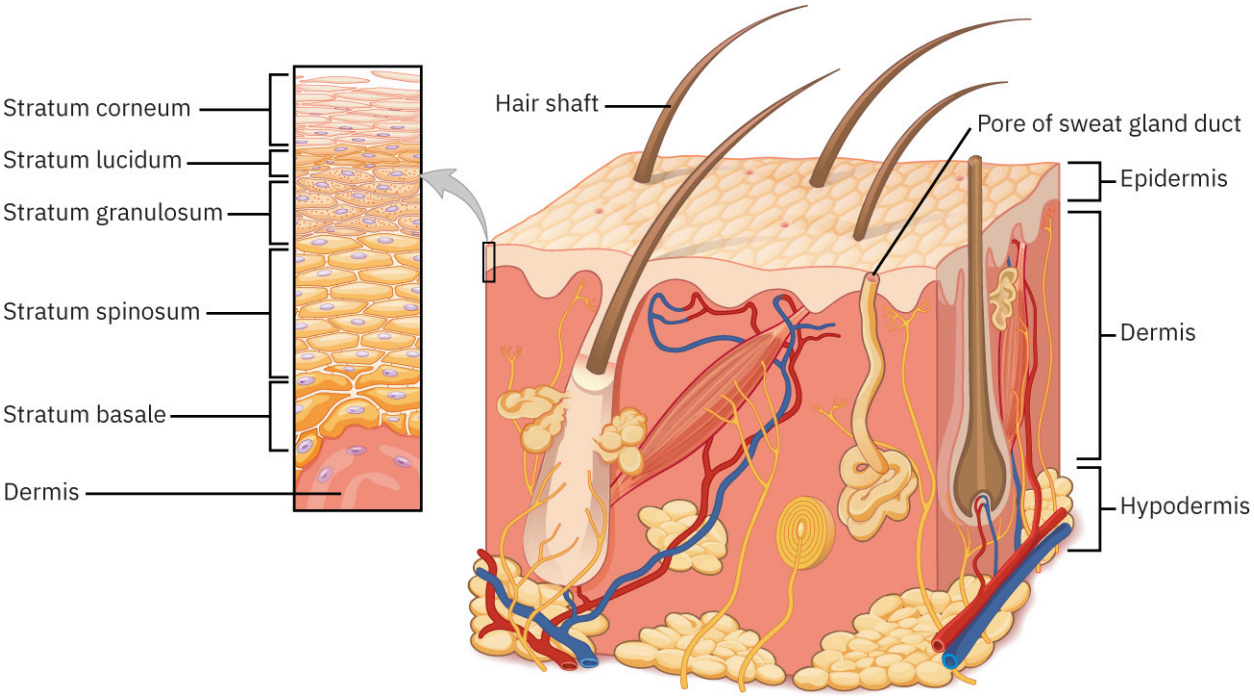

FIGURE 14.2 The three layers of the skin—the epidermis, the dermis, and the hypodermis—contain hair follicles, glands, vessels, and nerve endings. The skin also contains sweat glands that produce sweat and sebaceous glands that secrete sebum. (modification of work from OpenStax *Anatomy and Physiology*, 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The hair shaft comes through the epidermis, from the roots in the dermis. Hair and nails are formed from **keratin**, a skin protein. Sebaceous glands excrete sebum to keep the skin soft and protect against water loss. The sweat glands excrete salt and water to cool the body when its temperature increases (Kim and Dao, 2023). For more information about the skin breakdown and healing, refer to Chapter 28 Inflammation and Healing.

Atopic Dermatitis (Eczema)

A type of eczema, **atopic dermatitis** (AD) is a chronic skin condition in which a person has a dysfunctional skin barrier that allows outside substances to penetrate the skin easily, which results in dry and red areas of skin. Because it is the most common type of eczema, the two terms are commonly interchanged. Although this condition is more common in children, it is also common in adults (Nemeth & Evans, 2022). According to the Centers for Disease Control and Prevention, 7.3% of adults and 10.8% of children in the United States have atopic dermatitis (Centers for Disease Control and Prevention, 2023).

Pathophysiology

In AD, the skin is more susceptible to pathogens (e.g., bacteria) and is easily irritated by allergens. The skin is also more susceptible to water loss (Nemeth & Evans, 2022).

There are several risk factors for AD, including genetics or a family history of AD, a compromised immune system, and epidermal dysfunction. The full disease process is not entirely clear, and research is ongoing (Kim et al., 2019). However, the prevailing opinion is that a specific gene is linked to development of AD, causing corneocytes (cells that make up the outer layer of skin) in the skin to not be as tightly packed and creating separation in the skin barrier (Nemeth & Evans, 2022). Looking at immune system dysfunction, there is often an imbalance of T cells, which causes cytokine release and inflammatory response. Epidermal abnormalities of the skin's epithelial cells also contribute to eczema and its symptoms (Kim et al., 2019).

Clinical Manifestations

The most common clinical manifestation of AD is itching, and the patient's skin may appear scaly (Figure 14.3), with small areas of **excoriation**, where the skin is broken from scratching and may bleed or ooze in severe cases. Other symptoms may be red and/or dry patches of skin, skin thickening, and **lichenification**, where the skin becomes thick and leathery over time in an area that is frequently scratched. Atopic dermatitis can occur anywhere on the body, but it is most commonly found where joints are flexed, such as behind the knees and the antecubital fossa, as well as the wrists, ankles, and elbows (Nemeth & Evans, 2022). An AD flare-up can be triggered by allergens or stress, or with no warning.

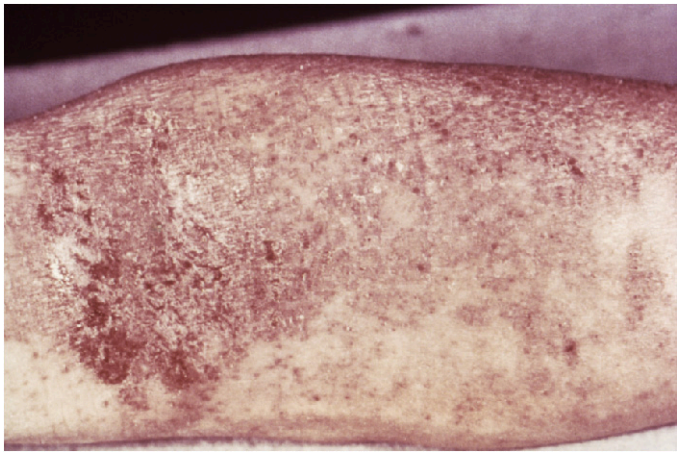

FIGURE 14.3 The erythematous, crusty rash that is typical of AD. In this image, the rash on the backside of the knee, which is a common location of AD. (credit: "ID# 4506" by CDC/Public Health Image Library, Public Domain)

Assessment and Diagnostics

The nurse will most likely notice small areas on the skin with abnormal redness. The nurse should ask the patient about a familial or personal history of AD and ask if the patient has any specific triggers that cause symptoms. The nurse should also ask about symptom onset, location, duration, and rash characteristics, as well as about alleviating or aggravating factors as well as timing and severity of symptoms.

Usually, a diagnosis of AD is based on the patient's symptoms and clinical presentation. Laboratory testing is not indicated unless allergens are suspected to be the cause (Nemeth & Evans, 2022). The health-care provider may ask about steroid use or environmental triggers, like cigarette smoke, soaps, or detergents. If a diagnosis is still not clear, the health-care provider may order a skin biopsy of the rash (National Institute of Arthritis and Musculoskeletal and Skin Diseases, 2022). If allergies are suspected, the health-care provider may order a scratch test for allergies. If health-care provider suspects immune system problems, tests for immunoglobins, an antinuclear antibody test, or other bloodwork may be helpful. The nurse can look for these results in the patient's chart.

Nursing Care of the Patient with AD

When caring for a patient with AD, it is important to understand the patient's past medical history. Be sure to ask the patient if they have a family history of atopic dermatitis, because the condition can be linked to a specific inheritable gene. The nurse can provide both pharmacological and nonpharmacological interventions, with a health-care provider's order, to assist with symptom relief and treating AD. Pharmacological interventions include topical emollients or antibiotics and oral antihistamines for itching. Nonpharmacological interventions include removing possible triggers and promoting hydration and skin integrity.

Recognizing and Analyzing Cues

The nurse may notice the patient is itchy and has areas of dry skin. Some areas may appear **erythematous** (abnormally red) and with mild to moderate excoriation. If the patient is scratching the areas frequently, the nurse may recognize skin thickening, oozing, weeping, or bleeding. The nurse should ask the patient the following questions:

- When did the symptoms start?
- Does anything aggravate the symptoms?
- Have you tried any treatments, and have they worked?
- Do you have any known environmental allergies?
- Does anyone in your family have similar symptoms or been diagnosed with eczema?

The patient may mention a specific trigger that causes their skin to break out, such as certain detergents or animal dander; however, there is not always a specific trigger. All the mentioned clinical manifestations can indicate AD, psoriasis, hives, skin allergies, or other skin disorders (Nemeth & Evans, 2022).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The priority nursing hypothesis related to AD is typically impaired skin integrity. If specific environmental allergens have been identified, the nurse should educate the patient to avoid these. If the triggers cannot be removed or the patient is experiencing itching, the nurse can request an order from the health-care provider for bedtime oral antihistamines. Oral antihistamines are preferred to be administered at bedtime because they act more as a sedative than itch relief; if administered during the daytime, they can cause unwanted drowsiness.

Because AD causes water loss from the skin, hydration is key. The nurse promotes a daily skin-moisturizing routine with oil-based ointments and lotions instead of water-based lotions. Water-based lotions do not hold the skin's moisture as long as oil-based ointment. Lotions should be fragrance-free because fragrances can sometimes be a trigger to AD. A daily moisturizing regimen may not be enough to help the patient's skin condition from worsening. Therefore, the nurse would discuss this with the provider and request an order for a topical anti-inflammatory or steroid (Kim, 2023).

Because AD is caused by dysfunction of the skin barrier, the patient is more likely to develop secondary fungal or bacterial infections, such as with *Staphylococcus aureus* (Nemeth & Evans, 2022). The nurse should frequently examine the patient's skin for signs and symptoms of infection. Signs and symptoms to look for include increased redness, swelling, and pus or unusual colored discharge from the areas; sometimes, yellow crusts will form over the areas of excoriation (MedlinePlus, 2023). If the nurse notes signs of infection, they should alert the health-care provider, and a topical and/or oral medication may be prescribed to treat for secondary infection. Topical mupirocin is commonly prescribed for bacterial infections and ketoconazole for fungal infections (Nemeth & Evans, 2022).

Evaluation of Nursing Care for the Patient with AD

After the nurse has implemented interventions, they must evaluate their effectiveness. The nurse observes for signs

of improvement to the patient's skin, including no new impairment of skin integrity.

CULTURAL CONTEXT

Skin Tone Variations and Symptom Presentation in Atopic Dermatitis

Atopic dermatitis (AD) can manifest differently depending on the patient's skin tone. In lighter skin tones, AD typically presents as red, inflamed patches. However, in darker skin tones, these patches may appear darker, greyish, or purplish rather than red. Postinflammatory hyperpigmentation, which leaves dark spots where the eczema was active, is more common in individuals with darker skin tones.

Hair Texture and Scalp Care

Patients with different hair textures may experience atopic dermatitis on the scalp differently. For those with coarser or curly hair, AD symptoms on the scalp might be overlooked due to the density and texture of the hair. Special attention should be given to thoroughly examining the scalp and providing tailored advice on managing scalp dermatitis without causing damage to the hair. This may include recommending specific hair-care routines or products that are gentle on both the skin and hair.

Cultural Practices and Treatment Adherence

Cultural beliefs and practices can influence how patients perceive and manage AD. Some cultures may prefer natural or home remedies versus prescribed medications, which can affect treatment adherence. Nurses should engage in open, respectful conversations to understand the patient's cultural preferences and integrate culturally acceptable treatment options. Providing education on the effectiveness and safety of prescribed treatments while also respecting traditional practices can enhance adherence and outcomes.

Effect on Nurse-Patient Communication

Effective communication is essential for understanding and addressing cultural differences in managing AD. Nurses should use culturally sensitive language and ask open-ended questions to better understand the patient's experiences and preferences. Providing educational materials in the patient's preferred language and considering literacy levels can also improve aid understanding and management of the condition.

Evaluating Outcomes

When evaluating desired outcomes, the nurse should ensure that the patient's AD is improving. The patient would report decreased itching, and the areas of healing AD would show decreased redness. If the patient had previous signs of infection, the nurse would expect the patient's skin to improve in appearance, showing decreased redness, swelling, and discharge from the infected areas. The nurse would still encourage a daily moisturizing regimen for the prevention of AD flares (National Institute of Arthritis and Musculoskeletal and Skin Diseases, 2022).

Medical Therapies and Related Care

Suppose symptoms do not seem to be improving or are worsening. In that case, the nurse can also recommend that the provider refer the patient to a dermatologist, who is a doctor specializing in treating skin disorders. If an allergy is suspected to be triggering AD flares, the nurse should be aware that the patient may need to see an allergist. Sometimes AD can lead to secondary infections; in those cases, the nurse should ask for help from a wound care or infectious disease provider (National Institute of Arthritis and Musculoskeletal and Skin Diseases, 2022). To promote wound healing, the nurse can also seek recommendations from a nutritionist. A high-protein diet can promote wound healing, as can dietary supplements. The nutritionist may also be able to identify foods that are causing skin reactions. Some common foods are wheat, eggs, and dairy products (Bemak, 2018).

Psoriasis

The chronic dermatological disorder characterized by the proliferation of skin cells and chronic inflammation is called **psoriasis** (Nair & Badri, 2023) (Figure 14.4). It affects more than 7.5 million people in the United States, about 3% of the population (Armstrong et al., 2021).

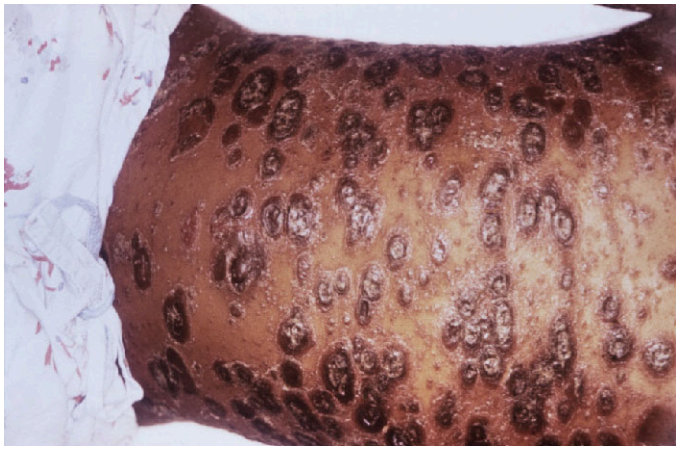

FIGURE 14.4 Numerous red, elevated, scaling lesions due to psoriasis. (credit: "ID# 5503" by CDC/Gavin Hart/Public Health Image Library, Public Domain)

Pathophysiology

Psoriasis is characterized by the proliferation of skin cells, specifically keratinocytes, which are activated by T cells infiltrating the skin. The proliferation of keratinocytes causes thickened skin or areas of thick plaques to form. A **plaque** is a raised lesion on the skin. This can lead to **epidermal** hyperplasia, thickening of the epidermis, and **parakeratosis**, a condition in which keratinocytes do not fully reach maturity. It also causes a skin inflammatory immune response through the cytokine response (Nair & Badri, 2023).

Psoriasis is an autoimmune disorder. An autoimmune disorder occurs when the body attacks its own cells and natural defenses. Because this condition affects the entire body, people with psoriasis may present not only with skin issues but also joint pain, nail changes, and poor sleep. It has also been linked to several inherited genes (Rendon & Schakel, 2019). The pathogenesis of psoriasis is unclear, although there is some indication that triggers (e.g., allergies, stress, dry skin, injuries) can potentiate a flare (MedlinePlus, 2022).

Clinical Manifestations

There are many types of psoriasis; the most common is plaque psoriasis. When observing plaque psoriasis, there are often well-defined thick patches of reddened skin with a silverly scale appearance. Common areas where plaque psoriasis is found are the elbows and knees, but it can be found anywhere on the body, like the scalp and soles of the feet (MedlinePlus, 2022). Other types of psoriasis will present with varying signs (e.g., itching, dry or scaly skin, joint achiness, thickened nails), depending on the type of psoriasis (Nair & Badri, 2023). These are summarized in Table 14.1.

Type	Clinical Manifestation	Common Location(s)	Image
Plaque psoriasis	Dry, itchy, raised skin plaques Varies in number Varies in color	Elbows, knees, lower back, scalp	 (credit: CDC/ Dr. N.J. Fiumara/Public Health Image Library, Public Domain)
Nail psoriasis	Nail pitting Abnormal nail growth Nail discoloration Nail separation from nail bed (**onycholysis**) Crumbling nails	Fingernails, toenails	 (credit: "Psoriasis fingernail" by "Fluzwup"/Wikipedia, Public Domain)
Guttate psoriasis	Small, drop-shaped scaling spots	Trunk, arms, legs	 (credit: modification of "Figure 1 Small, red, drop-like lesions of Guttate psoriasis located at the hand (A)" by Theocharis Koufakis and Ioannis Gabranis/National Library of Medicine, CC BY 2.0)
Inverse psoriasis	Inflamed, smooth patches	Groin, buttocks, breasts	 (credit: CDC/ Dr. Gavin Hart/Public Health Image Library, Public Domain)

Type	Clinical Manifestation	Common Location(s)	Image
Pustular psoriasis	Pus-filled blisters Varies in patch size	Palms, soles	 (credit: Roland Tanglao/Flickr, CC BY 2.0)
Erythrodermic psoriasis	Peeling rash Itchy or burning Short or long-term	Entire body	 (credit: CDC/ Public Health Image Library, Public Domain)

TABLE 14.1 Type of Psoriasis (Mayo Clinic, 2024)

Assessment and Diagnostics

While assessing the skin, the nurse can recognize psoriasis by identifying well-defined thick patches of reddened skin with a silvery scale appearance. Because psoriasis has a genetic component, the nurse should ask the patient about any familial history of psoriasis or skin conditions. The nurse asks if anything triggers the patches to appear or itch and if the patient has any autoimmune disorders. Some laboratory tests the health-care provider may have already ordered are a complete blood cell count (CBC), rheumatoid factors, erythrocyte sedimentation rate (ESR), and uric acid level. The nurse can look for previous results in the patient's chart.

Typically, a diagnosis of psoriasis is based on the patient's symptoms, clinical presentation, and how the skin condition appears, such as whether it is macular or popular. A skin biopsy may be taken for an accurate diagnosis, because psoriasis can resemble other skin conditions. The health-care provider can order additional blood tests to help determine the cause or exact etiology; these tests may include renal and liver function panels, a pregnancy test, and hepatitis serology (Nair & Badri, 2023). Elevated rheumatoid factor level, uric acid levels, and ESR can indicate psoriasis.

Nursing Care of the Patient with Psoriasis

When caring for patients with psoriasis, the nurse recognizes and analyzes patient cues and implements nursing interventions. Nursing care for patients with psoriasis involves recognizing and analyzing various patient cues, including skin assessment, symptom severity, and psychosocial effects. Interventions focus on skin care management with moisturizers and topical treatments, systemic and phototherapy monitoring, and symptom-relief strategies for itching and pain. Nurses also provide education on trigger avoidance and healthy lifestyle modifications, and offer psychosocial support through counseling and support groups. By coordinating with interdisciplinary teams and advocating for patients, nurses ensure comprehensive care that improves patient outcomes and quality of life.

LINK TO LEARNING

Health-care providers often use the Psoriasis Area and Severity Index (PASI) tool (https://openstax.org/r/77Psoriasis) to determine the severity of a patient's psoriasis when prescribing medication and appropriate treatment. This helps determine and guide the appropriate treatment. Nurses can use this also use this tool as a reference to help guide their nursing interventions and expected outcomes. They can look through the health-care providers notes to determine the patient's PASI score.

Recognizing and Analyzing Cues

The patient may report itchy and dry skin. The nurse should assess the patient for psoriatic plaques on the elbows, knees, or other areas of the body and ask the patient about their family history of skin disorders. The nurse can ask the patient when the symptoms started, if they are reoccurring, and if there are any specific triggers. They can also ask what treatments the patient has tried and if they helped (Nair & Badri, 2023). If the patient reports a familial history of psoriasis and the nurse notices the silvery patches of skin, this may indicate the patient has a form of psoriasis.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The priority nursing hypothesis for psoriasis is impaired skin integrity. Both pharmacological and nonpharmacological interventions are aimed at providing symptom relief and treatment. The nurse promotes a daily skin moisturizing routine with oil-based emollients and moisturizers to create a skin barrier and aid skin healing. Topical treatments, such as ointments or creams, are used in mild cases of psoriasis. Some examples include cortisone creams, coal tar, retinoids, or dithranol. Coal tar is a medicine used to help with skin itching and dryness by slowing skin cell growth (Nair & Badri, 2023).

Another treatment the provider might prescribe is **phototherapy**, which is ultraviolet light exposure to the skin. The nurse would ensure the patient receives this treatment by coordinating with the health-care team for phototherapy scheduling. For more severe cases of psoriasis, a systemic medication (e.g., methotrexate) may be prescribed by the provider to suppress the patient's immune system. Because psoriasis is an autoimmune condition, suppressing an inflammatory response with medications can help resolve symptoms. Some providers may also prescribe biologics, like infliximab or adalimumab (MedlinePlus, 2022). If the patient is prescribed any systemic medications, the nurse would administer these as prescribed and monitor the patient's liver and renal function, because these medications can increase values of biomarkers (e.g., alanine aminotransferase [ALT] levels, ESR). If the patient's immune system is impaired, infections are more likely to develop (Nair & Badri, 2023). Therefore, the nurse would also monitor for serious infections like tuberculosis and hepatitis.

LINK TO LEARNING

Read this article to learn more about biologics (https://openstax.org/r/77Biologics) and their role in treating psoriasis.

If the patient has identified specific triggers such as cold and dry conditions, drinking excessive amounts of alcohol, or stress, the nurse should educate the patient to avoid these. The nurse should educate the patient on stress-reducing techniques that can reduce psoriasis flares (MedlinePlus, 2022). The nurse should also educate the patient about worsening symptoms (e.g., redness, swelling, unusual discharge) to monitor that might indicate infection due to impaired skin integrity. If the patient or nurse notices any of these issues, the nurse should alert the health-care provider, who may prescribe topical antibiotics, such as mupirocin (Nair & Badri, 2023).

Evaluation of Nursing Care for the Patient with Psoriasis

Once the nurse has implemented pharmacological and nonpharmacological interventions, they must evaluate the effectiveness of the interventions. The nurse observes signs of improvement to the patient's skin and symptoms and assesses for no new or worsening signs of impaired skin integrity.

Evaluating Outcomes

Psoriasis is a chronic disease, meaning the patient will have periods of remission, when they have little to no symptoms. The nurse should see a desired outcome of treatment, including skin healing, improvement of patchy areas, and decreased skin thickness, redness, and scaly appearance. The patient's skin should also not show any signs or symptoms of infection, impaired skin integrity, or inflammation. If the patient was prescribed any medications, the nurse should reinforce medication compliance by educating the patient on the importance of continuing the treatment regimen. If the patient is taking systemic medications, the nurse would expect the patient's renal and liver function test results to be within normal limits. Renal function tests might include glomerular filtration rate (GFR) or creatinine level. Liver function tests include measuring ALT, aspartate aminotransferase (AST), and alkaline phosphatase (ALP) levels to make sure liver function is not impaired while the patient is receiving biologic medications. In addition, the patient would not show any signs of serious infection, like tuberculosis or hepatitis (Nair & Badri, 2023).

If additional areas of psoriasis form or worsening of symptoms or erythema are noted, the nurse should alert the health-care provider and suggest additional treatment, like adding systemic medication, if not already prescribed. The nurse would also evaluate the effectiveness of their education, ensuring the patient understands the importance of adhering to medications and avoiding triggers (Nair & Badri, 2023).

Medical Therapies and Related Care

Treatment of psoriasis often involves a dermatologist; if the patient has not already been referred to one, the nurse may suggest a referral. Psoriasis can cause secondary infections that may require assistance from a wound care nurse or infectious disease specialist, especially if the patient takes biologics or systemic medications. If an allergy is a suspected trigger, the nurse sends a referral to an allergist from the health-care provider. Depending on the area and type of psoriasis, additional referrals to a rheumatologist for autoimmune causes, and nephrologist, for kidney causes, may be warranted. If the patient's psoriasis is around or near the eyes, a referral to an ophthalmologist is needed (Nair & Badri, 2023).

14.2 Burns

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the incidence and prevalence of burn injuries
- Discuss the pathophysiology, risk factors, and clinical manifestations of burns
- Describe the diagnostic tests used and laboratory values observed for burn injuries
- Apply nursing concepts and plan associated nursing care for the patient with burns
- Evaluate the efficacy of nursing care for patients with burns
- Describe the medical therapies that apply to burn injuries

A **burn** is an injury to the skin from heat or chemicals. It can occur due to a variety of reasons, including hot liquids, electricity, fire, or heat or sun exposure. Depending on the type and severity of the burn, a patient can have life-threatening or serious complications, such as secondary infections, hypovolemia, hypothermia, and sepsis. As a nurse, you must understand the different types of burns, assessment techniques, and appropriate nursing care.

Incidence and Prevalence

As of 2023, the World Health Organization estimated that, globally, approximately 180,000 deaths occur every year from burn injuries (World Health Organization, 2023). The American Burn Association reported in their 2018 update that approximately 486,000 burn injuries occur every year in the United States (American Burn Association, 2018). Thermal injury is the main cause overall, accounting for 86% of burns, whereas electrical (4%) and chemical (3%) burns make up only a small portion of burn injuries.

Injuries from flames and scald burns are the most common across the population. Flame burns are more common in adults; children (aged <5 years) are more likely to suffer scald injuries. Notably, burn occurrences disproportionately affect individuals from low- and middle-income backgrounds, particularly in regions with fewer economic resources (Schaefer & Szymanski, 2023).

Severity and Survival

Burns can range from minor to severe, with the mortality rate increasing along with the severity of the burn. Mortality ranges from 3% to 55% with more severe burns leading to death. For adults, severe burns are usually those that cover more than 20% of the body or total body surface area (TBSA). For children, a burn covering more than 10% of their TBSA is considered severe (Gauglitz & Williams, 2023).

All burns must be thoroughly assessed to determine thickness, the percentage of TBSA involved, and if there are any life-threatening complications. Methods of calculating TBSA are discussed later in this chapter. Nurses should follow the ABCDE assessment method when initially triaging and caring for a burn patient. The ABCDE method stands for (in order of priority):

1. Airway: patency
2. Breathing: oxygen saturation and respiratory rate
3. Circulation: blood pressure, heart rate, and fluid resuscitation
4. Disability: neurological status
5. Exposure: temperature

For burns, ABC, followed by fluid resuscitation, take priority. More about the ABCDE can be found in the Chapter 33 Emergency Care chapter. For example, when using this method, the nurse would prioritize airway assessment and management ahead of any issues with circulation.

There are specialized burn injury hospitals and facilities throughout the country. However, not all patients come to burn centers for initial treatment. Therefore, a nurse in a typical emergency department should work with the health-care team to determine the severity of the patient's burn injuries and discuss if the patient needs to be transferred to a burn facility (Gauglitz & Williams, 2023).

LINK TO LEARNING

The American Burn Association has a website where you can find burn center locations (https://openstax.org/r/77BurnCenter) throughout the country.

Emergent Care

Following the ABCDE assessment method, the health-care team (i.e., nurse, respiratory therapist, health-care provider) will simultaneously assess the patient's airway for patency and then address the patient's breathing. Then, the team will assess the patient's respiratory rate and oxygen saturation, along with any other compromising issues (e.g., smoke inhalation) to determine if the patient requires oxygen treatment. Depending on the severity of the burn injury, the health-care provider may have to intubate the patient and provide respiratory support with a ventilator.

After establishing the patient's airway, the patient's circulation would be assessed, and fluid resuscitation may be indicated; obtaining intravenous (IV) access and controlling areas of hemorrhage are top priorities in burn care. Fluid resuscitation is necessary for the body and skin's hydration status because much of the vascular volume is lost through the skin with a burn. Adequate IV fluids are also needed to maintain vital signs within normal limits, including blood pressure support through intravascular volume. The nurse would then assess and address concerns related to disability or the patient's neurological status. Lastly, the nurse would collaborate with the health-care team to determine exposure. Exposure includes assessing the patient's temperature and skin, determining if warming measures are needed, assessing thickness of the burns, and calculating the TBSA (Gauglitz & Williams, 2023). For more information about the ABCDE triage method and interventions, see Chapter 33 Emergency Care.

Type of Burn Injuries

Burns can occur from different heat sources, causing different types of burn injuries. The main types of burns are thermal, chemical, electrical, and radiation. A **thermal burn** is the most common type of burn and is caused by an external heat source, like flames, steam, or hot liquids. A **chemical burn** is caused by hazardous chemicals, like acids or strong detergents. An **electrical burn** is caused by exposure to electricity or electrical currents. A **radiation burn** occurs from exposure to radiation sources, such as sunlight or machines that emit radiation, during some

cancer treatments (Warby & Maani, 2022). Burns are also classified by severity, ranking from least severe to most severe. These range from first-degree to sixth-degree burns and are further outlined in the following sections.

First-Degree Burns

A **first-degree burn** is the most superficial type of burn and is considered minor. It affects only the epidermis, or the outermost layer of the skin. First-degree burns are also called superficial thickness burns. An example of a first-degree burn would be a sunburn without any blisters, or one caused by touching a hot pot on the stove and quickly letting go (Warby & Maani, 2022).

Pathophysiology

First-degree burns affect only the skin's epidermal, or outermost, layer. When a burn source affects the skin, it causes protein denaturation or breaking of the protein linkages of the epidermis. Collagen, which helps the skin's elasticity, is also damaged. This causes the skin cells to die, a condition called necrosis (Pencle et al., 2022). After the burn injury occurs, three zones of injury arise: the zones of coagulation, statis, and hyperemia (Figure 14.5). The **zone of coagulation** is the central area of a burn where tissue has been irreversibly damaged and coagulated. The **zone of stasis** is the area surrounding a burn where the tissue has decreased perfusion, but the skin is still potentially viable. This is important for wound healing. Lastly, the **zone of hyperemia** is the outermost area of a burn where tissue is inflamed and has increased blood flow, typically recovering without intervention (Jeschke et al., 2020).

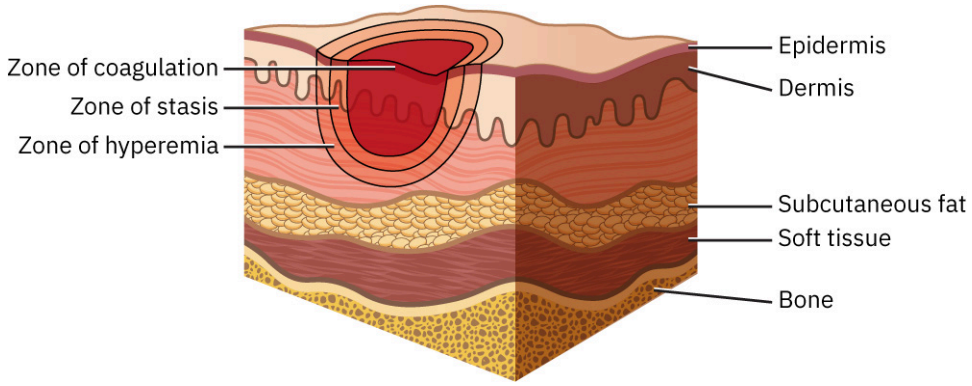

FIGURE 14.5 This image shows the zones of injury when a burn occurs. The zone of coagulation is the area with the most damage and is centrally located. The zone of stasis has decreased tissue perfusion, but the skin will still potentially heal. The zone of hyperemia is the outer layer, which is the extent of the tissue perfusion. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Clinical Manifestations

Clinical manifestations of first-degree burns include erythema, or redness, to the burned area, which can appear red or pink (Figure 14.6). Examples are a sunburn that does not blister or a minor burn from a stovetop. These burns may have minor skin swelling and are dry; they do not appear moist. First-degree burns will not form blisters and usually heal without scars. Pain associated with first-degree burns can be mild to moderate, depending on the area affected (Warby & Maani, 2022).

FIGURE 14.6 A first-degree burn appears pink, and the skin is dry. (credit: "Sunburn" by Beatrice Murch/Flickr, CC BY 2.0)

Assessment and Diagnostics

The nurse should assess the patient's skin for the characteristics of a first-degree burn. The nurse should ask the patient how and when they were burned, what caused the burn (i.e., source), and if they have any pain (Pencle et al., 2022).

Diagnosis of first-degree burns is based on clinical presentation. In a light-skinned patient, the nurse would note pink to red skin; if the patient's skin is darker, the burn may be reddish to brown. The burn will appear dry, without blisters, and only affects the top layer of skin. The nurse should also calculate the TBSA of first-degree burns using the Rule of Nines. The Rule of Nines is a quick tool that assigns a certain percentage to a body area, based on the surface area, so the person calculating can quickly estimate TBSA (Figure 14.7). Most first-degree burns are treated outside of the hospital setting and do not require additional diagnostic tests or laboratory and blood work (Pencle et al., 2022).

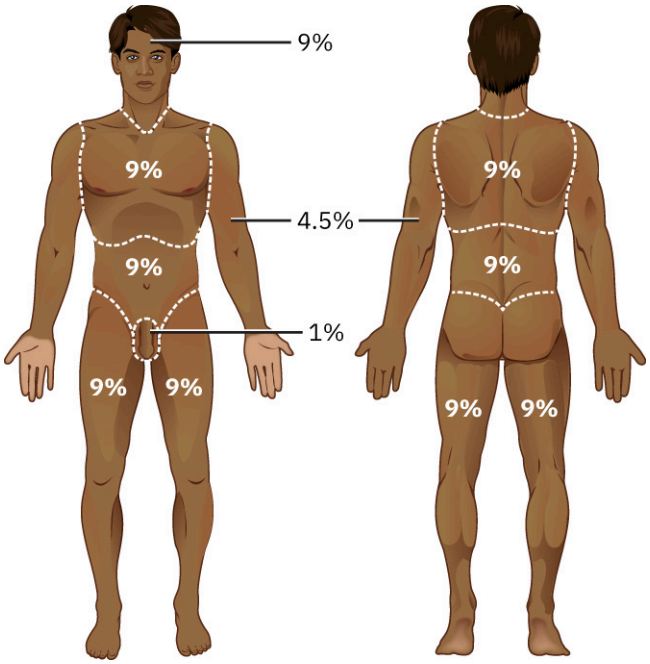

FIGURE 14.7 The Rule of Nines is used to calculate the TBSA that is covered in burns. Anterior and posterior portions are separate, and the areas are summed to a total score. For example, if a person is burned on their anterior and posterior bilateral upper arms, the TBSA would total 18% (4.5% for left anterior arm + 4.5% for left posterior arm + 4.5% for right anterior arm + 4.5% for right posterior arm). (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Nursing Care of the Patient with First-Degree Burns

When caring for a patient with a first-degree burn, it is important to understand how the burn occurred, the heat

source, and the patient's symptoms. The nurse will also assess and document the burn area(s) and calculate the TBSA affected by the burns, if extensive. The nurse will also provide pharmacological and nonpharmacological interventions and wound care education as ordered (Pencle et al., 2022). Nursing care for the patient presenting with a burn should follow these steps:

1. Identify heat source and take the patient's vital signs.
2. Address airway and breathing problems, if any.
3. Classify burns as first, second, or third degree.
4. Calculate the TBSA.
5. Provide remaining nursing interventions following the ABCDE model.

INTERDISCIPLINARY PLAN OF CARE

Interdisciplinary Care of the Burn Patient

Team members may include:

- Burn surgeon: Leads the medical management, performs surgeries for debridement and grafting, and oversees overall treatment plan
  - Interventions include surgical interventions, wound care, monitoring for complications, and coordinating with other team members for comprehensive care.
- Wound nurse or burn nurse: Provides specialized wound care, pain management, and education on burn care
  - Interventions include dressing changes, administering medications, monitoring vital signs, and patient and family education on wound care and prevention of infection.
- Physical therapist: promotes mobility, prevents contractures, and enhances functional recovery
  - Interventions include range of motion exercises, strength training, mobility aids, and positioning techniques to prevent deformities.
- Occupational therapist: Assists in regaining independence in daily activities and improving fine-motor skills
  - Interventions include activities of daily living (ADLs) training, splinting, adaptive equipment, and techniques to improve dexterity and coordination.
- Social worker: Provides psychosocial support, resources for coping, and assistance with discharge planning
  - Interventions include counseling, connecting with support groups, coordinating community resources, and addressing financial or housing concerns.
- Nutritionist: Ensures optimal nutritional support for wound healing and overall recovery
  - Interventions include nutritional assessment, high-protein diet plans, vitamin and mineral supplementation, and monitoring for malnutrition.
- Psychologist/psychiatrist: Addresses mental health issues such as anxiety, depression, and post-traumatic stress disorder (PTSD) related to the burn injury.
  - Interventions include psychological assessments, therapy sessions, support groups, and medication management if needed.
- Respiratory therapist: Manages respiratory complications, especially in patients with inhalation injuries
  - Interventions include monitoring respiratory status, providing oxygen therapy, ventilator support, and pulmonary rehabilitation exercises.

Recognizing and Analyzing Cues

When recognizing cues, the patient may report that they received a burn to their skin. Additionally, the nurse may notice a pink to red or brown area that appears dry and mildly swollen. Some skin conditions, like birthmarks, can be mistaken for burns, so the nurse should ask the patient about all areas. Also, the nurse analyzes these clues by asking the patient how they received a burn, when the burn occurred, and their pain level. If the patient can speak, the nurse can use the numeric pain scale. If the patient is unconscious or nonverbal, the nurse can assess the patient's vital signs (e.g., tachycardia or tachypnea) in conjunction with the approved facility pain scale, such as FACES or Pain Assessment in Advanced Dementia (PAINAD) Scale. The nurse should also ask the patient if they have tried any over-the-counter remedies or taken any medications for pain relief (Pencle et al., 2022).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The priority nursing hypothesis for first-degree burns is impaired skin integrity related to the burn injury. When generating solutions, the nurse can determine pharmacological and nonpharmacological interventions to promote impaired skin integrity with the outcome of the burn healing. First-degree burns are considered minor and can be treated mainly using the "Cs" of burn care (Schaefer & Szymanski, 2023):

- Cooling: In small areas, tap water or saline solution may help to prevent the burn from progressing burning and to reduce pain.
- Cleaning: Burns should be cleaned using a mild soap and water or a mild antibacterial wash. Large blisters are generally debrided. Small blisters and blisters involving the palms or soles are left intact.
- Covering: The burn may be covered using an absorbent dressing or specialized burn dressing over a topical antibiotic ointment or cream. A pharmacological intervention would be applying topical medications, such as silver sulfadiazine or aloe vera; an example of a nonpharmacological intervention is topical petroleum ointment.
- Comfort: For pain, over-the-counter pain medications (e.g., acetaminophen, ibuprofen) or prescription pain medications can be used. Some burned areas may be supported using splints, which may provide some comfort to the patient.

If the burn was due to sun exposure, the nurse educates the patient on preventive skin care, like applying sunscreen and avoiding sunlight during the hotter hours of the day.

Evaluation of Nursing Care for the Patient with First-Degree Burns

The nurse will evaluate the effectiveness of the pharmacological and nonpharmacological interventions related to impaired skin integrity. The nurse would expect a first-degree burn to fully heal within 5 to 10 days (Warby & Maani, 2022).

Evaluating Outcomes

The desired outcome is that the patient will not experience any signs of impaired skin integrity related to the burn injury. In a light-skinned person, the area would not be red or pink; in a dark-skinned person, erythema is not always apparent. In all patients, there should be no signs of infection. The skin would be completely healed, without a permanent scar in most cases. The patient would also note they have little to no pain to the area (Pencle et al., 2022).

Medical Therapies and Related Care

First-degree burns usually heal without complications. However, the health-care provider may refer the patient to wound care, if needed. Usually, this would be needed if the wound is not healing as expected or appears to become infected. Depending on the location of the burn, the patient may need home health assistance with wound care if they live at home alone. The nurse would recommend a referral to either home health or a case manager to coordinate wound care (Pencle et al., 2022).

Second-Degree Burns

A **second-degree burn** is a type of partial-thickness burn involving the epidermis and the dermis, which appears as red and blistering and can be very painful (Warby & Maani, 2022). Second-degree burns most often occur from hot liquids (e.g., hot grease, microwaved water), chemicals, or radiation.

Pathophysiology

Second-degree burns affect the skin's epidermis and part of the dermis. They can affect the superficial dermis or penetrate deeper. Similar to first-degree burns, protein denaturation—breaking of the protein bonds—occurs and collagen is damaged. Depending on how far the burn extends into the dermis, the skin can lose fluid and have decreased thermal regulation and sensation. With larger burns, covering greater than 20% of a person's body surface area, the body may produce a systemic inflammatory response, whereby fluid loss and shifts occur throughout the body. This can lead to septic or hypovolemic shock (Schaefer & Tannan, 2023).

Clinical Manifestations

Clinical manifestation of second-degree or partial-thickness burns includes erythema, blisters, and a wet appearance (Figure 14.8). The skin may swell and skin erythema will be blanchable with pressure. Blanching occurs

when the skin temporarily turns white after pressure is applied. Second-degree burns usually produce moderate to severe pain. This is because the patient's epidermis and dermis are damaged and nerve endings can be exposed and destroyed (Warby & Maani, 2022).

FIGURE 14.8 A second-degree burn appears wet. It will blister and be fluid-filled. (credit: "Second Degree Burn on Shoulder" by "Edge1665"/Wikimedia Commons, CC0 1.0)

Assessment and Diagnostics

The nurse should assess the patient's skin for the characteristics of a second-degree burn. The nurse gathers valuable information from the patient, detailing how and when the burn occurred, the heat source, and the patient's pain level (Pencle et al., 2022).

Assessment and diagnosis of burns are based on visualization of the skin and clinical presentation. The nurse would note the level of involvement of the patient's epidermal and dermal layers. The nurse would calculate the TBSA of second-degree burns to determine the percentage of the patient's body that is affected by burns (Schaefer & Szymanski, 2022).

Depending on the extent of the burns, the patient may require inpatient treatment. Additional laboratory and diagnostic tests may be ordered, including a CBC, comprehensive metabolic panel (CMP), arterial blood gases analysis, and other diagnostic tests. These tests assess the patient's overall condition, including oxygenation, kidney function, infection and other responses. If a smoke inhalation injury is suspected, chest X-rays and electrocardiograms (ECGs) may be ordered as well. The chest x-ray may show lung injury, whereas the ECG can show slight changes to cardiac function (Rice & Orgill, 2023).

Nursing Care of the Patient with Second-Degree Burns

When caring for a patient with a second-degree burn, the nurse must recognize and analyze patient cues. The nurse will carefully prioritize nursing hypotheses and generate both pharmacological and nonpharmacological solutions.

Recognizing and Analyzing Cues

The nurse will first start by recognizing patient cues and gathering relevant information. The nurse should obtain a history of the burn, take the patient's vital signs, and assess the patient's pain level, which will likely be moderate to

severe. When assessing the burns, the nurse would look for the characteristics of a second-degree burns. The nurse would then analyze these cues to determine a priority nursing hypothesis.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

After the nurse has gathered and analyzed cues, they will determine the priority nursing hypothesis. Typically, the priority nursing hypothesis is impaired skin integrity for second-degree burns. However, if the extent of the burns covers a large percentage of the patient's body or if their vital signs are unstable, other nursing hypotheses may be a priority, like airway, breathing, or circulation issues. The nurse would follow the ABCDE assessment method when prioritizing. For example, if the patient has experienced smoke inhalation, impaired gas exchange might be the priority nursing hypothesis over impaired skin integrity (Rice & Orgill, 2023).

The nurse should then generate solutions for the priority hypothesis of impaired skin integrity by providing pharmacological and nonpharmacological interventions. Some solutions are wound care, pain control, and infection prevention. Any clothing or jewelry should be removed from areas near the burn. The nurse would then cool the patient's skin by either applying water or a saline solution and gauze. This prevents the burn injury area from extending deeper and supports skin cell repair. The nurse would then cleanse the burn with an antibacterial wash. If the health-care provider orders it, the nurse may remove larger blisters by gently applying pressure with gauze while leaving smaller ones intact. The nurse will then apply a topical ointment, like silver sulfadiazine or mupirocin, as ordered, and a nonadherent dressing to the burn areas, serving as barriers and protectants (Schaefer & Szymanski, 2022).

The nurse can also provide pain relief with ordered pain medications, such as IV morphine or other opioids. Ideally, the nurse would administer pain medications at least 30 minutes before providing burn care or completing dressing changes, because second-degree burns can be extremely painful. The nurse would assess the patient's burn injuries during dressing changes, ensuring there are no signs and symptoms of infection, and alert the health-care provider of any changes. Symptoms of infection may include fever, increased erythema, or yellow and foul-smelling discharge from the wound. Depending on the TBSA percentage of burns, the nurse may also need to provide IV fluid replacement. Burns covering a larger portion of the patient's body can lead to hypovolemia or fluid volume deficit (Rice & Orgill, 2023).

Evaluation of Nursing Care for the Patient with Second-Degree Burns

Next, the nurse will evaluate the effectiveness of interventions related to impaired skin integrity. Second-degree (or partial-thickness) burns usually heal within 3 weeks, and scarring is minimal (Warby & Maani, 2022).

Evaluating Outcomes

When evaluating outcomes related to impaired skin integrity, the nurse determines if their interventions were effective. First, the nurse would expect the patient's pain level to be tolerable prior to dressing changes. They would assess this by asking the patient their pain level (using an appropriate pain assessment tool) before, during, and after wound care. Nurses can also look for physiological clues that can indicate pain for unconscious patients, like tachycardia or tachypnea. As the burn heals, the nurse would expect the patient's pain to reduce over time. The nurse would expect the burn to begin healing and show no signs of infection; the burn should appear pink, and dry, with healing blisters. Depending on the timing of the desired outcome, the nurse would expect the patient's burn to almost be completely healed within 3 weeks. There may be some scarring present (Schaefer & Szymanski, 2022).

Medical Therapies and Related Care

Usually, second-degree burns heal within 3 weeks. Depending on the extent of the patient's burns and related injuries, the nurse may need to collaborate on patient care with other health-care team members. If the patient had smoke inhalation, collaborative care with a respiratory therapist and pulmonologist will be needed. To aid with wound care, a referral for a wound care nurse and other specialists may be placed by the primary care provider. To promote wound healing, a nutritionist may be consulted for dietary recommendations. If a secondary infection develops, the health-care provider may order a consultation with an infectious disease specialist and/or a pharmacist. Lastly, if the patient is discharged and needs help with wound care at home, an order for home health, case management, or wound care clinic may be needed.

Third-Degree Burns

A **third-degree burn** involves the epidermis, dermis, and subcutaneous structures and appears white or black, dry,

and leathery. Because third-degree burns involve all layers of the skin, they are also referred to as full-thickness burns. These burns require immediate medical attention because they can be life-threatening (Warby & Maani, 2022). Common causes of third-degree burns are extremely harsh chemicals, flames, or scalding liquids.

Pathophysiology

Third-degree burns affect the entire epidermis and dermis of the skin, extending into the subcutaneous tissue. These burns may also extend to and damage the underlying bones, tendons, muscles, and nerves. Because the nerve endings in the skin are destroyed by the burn, patients do not have pain. Third-degree burns are severe, no matter the size, and require treatment at a specialized burn center and skin grafting (Warby & Maani, 2022). They can also lead to fluid loss and decreased thermal regulation, depending on the percentage of the body the burn covers (Schaefer & Tannan, 2023).

Clinical Manifestations

Third-degree (or full-thickness) burns can appear white, black, or brown, look dry or leathery, and be nonblanchable. They may produce **eschar**, which is a piece of dead tissue that is cast off from the surface of the skin, particularly after a burn injury. It is usually a dark color and can be hard or soft, depending on the type and cause of the injury. The patient will not have pain, due to the destruction of nerve ending in the skin, and there may be exposed bone, tendon, or muscle tissue (Warby & Maani, 2022) (Figure 14.9).

FIGURE 14.9 A third-degree burn may appear dark and leathery. (credit: “8-day-old-3rd-degree-burn” by “Craig0927”/Wikimedia Commons, Public Domain)

Assessment and Diagnostics

The nurse should assess the patient’s skin for the characteristics of a first-degree burn and assess the patient’s pain level. Many patients with third-degree burns also have second-degree burns, so they may experience pain. Therefore, the nurse should still assess the patients for pain using the appropriate tool for the patient’s level of consciousness.

Diagnosis of third-degree burns is based on presentation and appearance. The health-care provider may order additional bloodwork and testing based on the extent of the burn injuries, the source of the burn, and whether the patient experienced smoke inhalation. Additional tests may include a CBC, CMP, arterial blood gas analysis, and other diagnostic tests. If the patient received the burn from an electrical shock, they would require an initial ECG and continuous ECG monitoring (Rice & Orgill, 2023). The health-care provider reviews the WBC count for indicators of infection and kidney function, and hemoglobin and hematocrit for fluid volume status. Arterial blood gases provide an accurate picture of the patient’s respiratory status; thus, arterial blood samples are used to measure the levels of oxygen, carbon dioxide, and blood pH, and these indicate how well the lungs are oxygenating the blood and removing carbon dioxide.

Nursing Care of the Patient with Third-Degree Burns

When caring for patients with third-degree burns, the nurse should be able to differentiate among the degrees, based on the patient cues and assessment. They would then determine appropriate nursing care.

LIFE-STAGE CONTEXT

Burns in the Older Adult

For older patients, consider asking them more relevant information to how they received the burn. Did they forget to use a mitt when removing a hot pan from the oven? Did they leave an electric blanket on their bed, causing a burn due to sensory issues? Sometimes the exact cause of the burn can lead down the path to other potential patient conditions to assess, like dementia or neuropathy.

Recognizing and Analyzing Cues

The nurse will first start the nursing process by gathering information and recognizing cues. The nurse will follow the ABCDE assessment method to identify and address any areas of immediate concern first. During this assessment process, the nurse should ask questions about how and when the patient received the burn, what heat source was involved, and any associated symptoms. The nurse will also complete their initial vital signs assessment, have the patient rate their pain, and assess the skin.

The nurse must then analyze the patient cues. For example, if the patient is having difficulty breathing, they may have smoke inhalation. Alternatively, the burn may have restricted the patient's breathing, or the patient may be anxious; the nurse will need to determine the correct option. The nurse should also be looking for cues consistent with third-degree burns. For example, if the burn is black, dry, and leathery, and the patient denies pain at the burn injury site, these cues are consistent with a third-degree burn. Other findings might indicate a different severity of burn (Gauglitz & Williams, 2023).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

After the nurse has analyzed cues, they will determine the priority nursing hypothesis following the ABCDE assessment method. If the patient has received burns to a large portion of their body or experienced smoke inhalation, the priority nursing hypotheses would be related to oxygen exchange or depleted fluid volume. However, typically, the priority nursing hypothesis for third-degree burns not covering a large portion of the patient's body is impaired skin integrity. The priority nursing interventions are dependent on the TBSA of burns (Rice & Orgill, 2023).

After the nurse determines the priority nursing hypothesis, they will generate solutions. Solutions related to impaired skin integrity are wound care, infection prevention, and care coordination with plastic surgery. Typically, patients do not have pain with third-degree burns, but pain medications may be needed for wound care; the nurse must consider this as a possible solution. A short-term outcome for impaired skin integrity may be preventing wound infection and compartment syndrome. The nurse would potentially set a long-term expected outcome of the patient's burn injury healing after 8 or more weeks (Schaefer & Szymanski, 2022).

The nurse then will act on the interventions they identified. If the patient is not already at a burn injury center, they should be transferred to a specialized burn center to provide quality care and resources. In the meantime, the nurse should work with the health-care provider to cleanse the wound and debride or remove dead tissue, and apply topical antimicrobial ointments. Depending on the extent of the burn injury, the nurse will also assess for signs of compartment syndrome around the burn site. This includes the taking patient's pulse and assessing skin color, along with any reports of numbness, tingling, or pain. If the nurse identifies signs of impending compartment syndrome, such as severe pain, pulselessness, swelling, or numbness and tingling, they should notify the health-care provider immediately. The nurse also must collaborate on patient care with other members of the health-care team because third-degree burns can require extensive **debridement**, which involves removal of damaged tissue around a wound to allow for new tissue to more easily grow. The nurse may need to coordinate consultations with general surgery, plastic surgery, and other surgical specialties, depending on the size and depth of the burn (Schaefer & Nunez Lopez, 2023).

As with other burns, the nurse would assess for signs and symptoms of infection and alert the health-care provider of any changes. Some common symptoms of infection include fever, increased erythema, or yellow and foul-

smelling discharge from the burn. Depending on the TBSA percentage of burns, the nurse may also need to provide IV fluid replacement, because burns covering a larger portion of the patient's body can lead to hypovolemia or fluid volume deficit (Rice & Orgill, 2023).

Evaluation of Nursing Care for the Patient with Third-Degree Burns

After the nurse has implemented their nursing care, they will evaluate the effectiveness of their actions. The nurse can evaluate both short- and long-term goals related to impaired skin integrity. Short-term goals may be to prevent infection and prevent any signs of compartment syndrome. A long-term goal may be for the wound to completely heal, which may take months to years, and will likely leave a permanent scar (Warby & Maani, 2022).

Evaluating Outcomes

For a short-term (and long-term) goal, the nurse would expect the patient's burn injury to show no signs and symptoms of infection. The patient may also require surgeries to help debride and cleanse the wound to prevent infection and promote healing. The nurse will also note no signs of compartment syndrome: no swelling, no decreased pulses to the affected area(s), or other signs. A short-term goal would be for the patient's WBC count to remain within normal range, indicating no signs of infection. A long-term goal would be evaluated after 8 weeks, when the nurse would expect the burn to be almost completely healed (Schaefer & Nunez Lopez, 2023).

Medical Therapies and Related Care

Typically, third-degree, or full-thickness, burns take at least 8 weeks to heal and may take even longer. The patient will require care from a collaborative health-care team. The nurse expects the patient to need referrals to wound care, plastic surgery, and potentially orthopedics if any underlying bone is involved. If the patient experiences smoke inhalation, the nurse should expect additional health-care team members to be involved in the patient's care, like a pulmonologist and respiratory therapist. Additionally, if a secondary infection develops, an infectious disease consultation may be ordered along with a nutritionist to promote wound healing. Once the patient is ready to be discharged home or another care facility, the nurse can potentially expect referrals for case management, home health, and wound care.

Toxic Epidermal Necrolysis and Stevens-Johnson Syndrome

Although not occurring from a burn injury, there are two disorders that can resemble partial-thickness burns and are often treated in similar ways. Both **Stevens-Johnson Syndrome (SJS)** and **toxic epidermal necrolysis (TEN)** are abrupt, rare skin reactions that involve loss of skin and sometimes mucosal membranes. In 80% of cases, medications cause these rare and life-threatening reactions. Some common medications that can cause these reactions include cephalosporins, allopurinol, phenytoin, among others (Oakley & Krishnamurthy, 2023).

Pathophysiology

The exact pathophysiology of SJS and TEN is unknown. The main theory is that the causative medication binds to the major histocompatibility complex type 1, causing a T-cell–mediated reaction. Another theory is that release of granulysin (a protein) and $CD8^+$ cells may lead to keratinocyte death and skin blistering (Bendetti, 2022).

The skin cell death that occurs causes the patient's skin to blister and slough off, which looks similar to a second-degree burn injury. Thus, patients with SJS or TEN are often treated at burn centers and burn units, because management is similar (Bendetti, 2022).

Clinical Manifestations

Usually, patients with SJS or TEN will present with fever and feeling generally unwell. They may also have upper respiratory symptoms. Over the course of a few days, they will develop a blistering skin rash, which can include mucosal membranes like the lips, mouth, and the gastrointestinal tract. Patients with TEN will likely develop widespread target-appearing, painful, blister-like erosions. Patients with SJS will have a similar, more localized, rash. Patients may also report a headache and sore throat. Because SJS and TEN can affect other body systems like the liver and kidneys, patients may also report symptoms related to the affected body system. Some symptoms may include nausea, vomiting, shortness of breath, or leg swelling (Oakley & Krishnamurthy, 2023). Multiorgan dysfunction syndrome (MODS) is also a possibility and is discussed in Chapter 23 Shock and Sepsis.

Assessment and Diagnostics

The skin of patients with SJS or TEN will appear similar to that of patients with second-degree burns. The

widespread rash looks like a target, and painful bister-like erosions often develop. The nurse should obtain the patient's history of illness and a personal history, including when their symptoms started, and ask the patient if they have started any new medications (Oakley & Krishnamurthy, 2023).

After the initial workup, the health-care provider may order laboratory tests, like a CBC, CMP, and liver and renal function panels. Patients with SJS or TEN usually have anemia, neutropenia, elevated transaminase levels, hyponatremia, and other abnormal laboratory values. To rule out other potential causes, the provider may order a skin biopsy and additional pulmonary or cardiac diagnostic tests, such as bronchoscopies, chest x-rays, and ECGs (Oakley & Krishnamurthy, 2023).

Nursing Care of the Patient with TEN or SJS

When caring for a patient with SJS or TEN, the nurse must recognize and analyze patient cues. Symptoms usually start with fever and malaise, with skin blistering appearing a few days later. The patient may have started taking a new medication or is taking one of the medications associated with developing TEN or SJS. The nurse will provide both pharmacological and nonpharmacological interventions to assist with symptom relief and treatment.

Recognizing and Analyzing Cues

The nurse will recognize cues by identifying relevant information and will start by asking the patient about symptom onset and current medications. The nurse will then take the patient's vital signs, ask about the patient's pain level, and assess the patient's skin. The patient's skin will likely have widespread blistering erosions that look like targets or bullseyes. The erosions can also affect the patient's mucosal membranes, like the mouth and lips, or the palms and soles of the feet; the nurse should examine these areas as well (Oakley & Krishnamurthy, 2023).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The nurse will determine the priority nursing hypothesis, which may be different for the acute and rehabilitation phases of SJS and TEN. However, the priority hypothesis is typically impaired skin integrity. If there is airway involvement, that takes priority, based on the ABCDE triage method. The nurse can generate pharmacological and nonpharmacological interventions to promote skin healing and prevent infection.

Of importance, the nurse would discontinue the administration of the medication causing SJS or TEN. The nurse can also provide daily skin care as ordered, which can include gently removing necrotic tissue, cleansing the wounds, and applying nonadherent dressings (Hanson & Bettencourt, 2020). The nurse should also assess for signs and symptoms of infection and collect wound cultures every 2 days of the skin lesions. If infection is present, the nurse would notify the health-care provider and administer antibiotics as ordered. The nurse should also frequently assess the patient's pain and provide pain medications as needed for pain relief. Depending on the condition of the patient, the health-care provider might include fluid replacement, monitor laboratory values, and provide supplemental oxygen, nutrition, and temperature control (Oakley & Krishnamurthy, 2023).

CLINICAL SAFETY AND PROCEDURES (QSEN)

Wound Care and Dressing Changes for Burn Patients

Purpose: To guide health-care providers in performing wound care and dressing changes for burn patients to prevent infection and promote healing.

QSEN Competencies: Patient-Centered Care, Safety, Evidence-Based Practice (EBP), Teamwork and Collaboration

Steps:

1. Gather supplies
    - Ensure all necessary supplies are available: sterile gloves, dressing materials, normal saline or wound cleanser, antibiotic ointment (if prescribed), and pain management medications.
2. Hand hygiene and PPE (Safety)
    - Perform hand hygiene thoroughly.
    - Don sterile gloves and other appropriate PPE to maintain a sterile field.
3. Assess the wound (Patient-Centered Care, Safety)
    - Inspect the burn wound for signs of infection, such as increased redness, swelling, warmth, or purulent

discharge.
    - Note the color, size, and depth of the burn.
4. Administer pain relief (Patient-Centered Care)
    - Provide prescribed analgesics prior to the dressing change to manage pain and minimize discomfort.
5. Clean the wound (Safety, EBP)
    - Gently clean the wound with sterile normal saline or an appropriate wound cleanser.
    - Use a gentle technique to avoid causing further trauma to the wound bed.
6. Apply antibiotic ointment (EBP):
    - Apply a thin layer of antibiotic ointment to the burn wound, if prescribed, to prevent infection.
7. Apply the dressing (Safety, EBP)
    - Cover the wound with a nonadherent dressing to protect the area and promote a moist healing environment.
    - Secure the dressing with appropriate bandaging materials, ensuring it is snug but not constricting.
8. Dispose of used materials (Safety)
    - Safely dispose of used dressing materials and gloves in accordance with infection control protocols.
    - Perform hand hygiene after disposing of materials.
9. Document the procedure (Teamwork and Collaboration, Safety):
    - Record the details of the wound care procedure in the patient's medical record, including wound appearance, any signs of infection, patient's pain level, and the type of dressing applied.
10. Educate the patient and family (Patient-Centered Care, Teamwork and Collaboration)
    - Provide education on wound care and signs of infection to the patient and their family.
    - Ensure they understand the importance of keeping the wound clean and dry and when to seek medical attention.

Evaluation of Nursing Care for the Patient with TEN and SJS

The nurse should evaluate the effectiveness of the pharmacological and nonpharmacological interventions related to impaired skin integrity. The course of SJS and TEN is divided into acute and rehabilitation phases, for which expected patient outcomes are different. The acute phase is the period when the patient is hospitalized, and the rehabilitation phase is the period after the patient is discharged from the hospital.

Evaluating Outcomes

When evaluating outcomes related to impaired skin integrity, the nurse would expect the patient's wounds to heal without any signs of infection. The patient's pain should also be controlled to a tolerable level. The nurse would expect the patient's laboratory values and thermoregulation to return to normal, with no fluid imbalances present (Oakley & Krishnamurthy, 2023).

Medical Therapies and Related Care

Care from a large interdisciplinary team is required for patients with SJS or TEN because these conditions affect multiple organ systems. Some specialists on the health-care team may include an intensivist and pulmonologist, dermatologist, urologist, gynecologist, ophthalmologist, and plastic surgeon. The patient will also need referrals to supportive services like wound care, nutrition, physical therapy, occupational therapy, and psychology (Oakley & Krishnamurthy, 2023).

Rehabilitation and Psychological Care for SJS or TEN

Patients with SJS and TEN usually require care in an intensive care setting and burn unit initially. This is because SJS and TEN affect multiple organ systems, requiring close patient monitoring. Once the patient has recovered from the acute phase, they will require rehabilitation. Rehabilitation can be completed either inpatient or outpatient, depending on the patient's ambulatory status at discharge. Patients who are not ambulatory will be transferred to an inpatient rehabilitation facility. Patients will require an extended period of physical and occupational therapy to gain strength and complete ADLs independently. The patient may also require pain management and care coordination for follow-up appointments and ongoing care (Shanbhag et al., 2020).

Additionally, patients with SJS and TENS will need psychological support because the illness can cause stress and PTSD. Patients may require a psychiatric evaluation and medications to help with stress symptoms. The nurse will help collaborate with inpatient psychiatric care while the patient is in the hospital and outpatient care when the

patient is discharged (Shanbhag et al., 2020).

14.3 Dermatologic Conditions

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations of various dermatologic conditions
- Describe the diagnostic tests used and laboratory values observed in dermatologic conditions
- Apply nursing concepts and plan associated nursing care for the patient with varying dermatologic conditions
- Evaluate the efficacy of nursing care for patients with various dermatologic conditions
- Describe the medical therapies that apply to treating various dermatologic conditions

Over the span of their careers, nurses will encounter various dermatologic disorders and conditions. Dermatologic disorders often only involve the skin and its layers, whereas integumentary disorders can involve the skin and its accessories, like hair, nails, and glands. As a nurse, it is important to be able to differentiate and understand the treatment of common skin conditions to provide quality patient care. For any slight changes in the patient's condition, the nurse should think about the most likely cause or condition. The nurse will also educate patients on risk factors, prevention, treatment, and follow-up care.

Contact Dermatitis

Inflammation or irritation of the skin is called **dermatitis**. There are several different types of dermatitis, including contact, seborrheic, and generalized exfoliative dermatitis. Each has different signs and symptoms.

Inflammation of the skin caused by direct contact with an irritant or allergens is called **contact dermatitis**. Allergic contact dermatitis occurs in approximately one in five people, making it a very common skin disorder. Some common agents causing contact dermatitis are latex, poison ivy, metals, and certain plants (Adler & DeLeo, 2021).

Pathophysiology

When a patient's skin is exposed to irritants, cytokines are released, causing an inflammatory response and skin barrier disruption. In allergic contact dermatitis, exposure to an allergen causes the skin's T cells to activate and the skin to react (Litchman et al., 2023). The allergic reaction is discussed in greater detail in Chapter 24 Management of Patients with Allergic Disorders.

Clinical Manifestations

Clinical manifestations of contact dermatitis include itching, stinging, and pain at the site where the contact occurred. Contact dermatitis commonly occurs on the hands but can occur anywhere on the body if an irritant is exposed to the skin. Depending on the stage of exposure (i.e., acute, subacute, chronic), contact dermatitis may appear differently (Figure 14.10). In the acute phase, the skin will be erythematous and have vesicles, or blisters, which are small, thin-walled sacs with filled with clear fluid. In the subacute phase, crusts may have formed over the acute lesions. During the chronic phase, lichenification (thick and leathery appearance of the skin) occurs (Litchman et al., 2023).

FIGURE 14.10 This patient has contact dermatitis after coming in contact with poison ivy. Notice the erythematous vesicles, which indicate contact dermatitis. (credit: "The aesthetic joys of poison ivy outweigh any pains of itching" by Danjo Paluska/Flickr, CC BY 2.0)

Assessment and Diagnostics

Depending on the stage of the contact dermatitis, the patient's skin will look different. The nurse can determine the stage based on the assessment.

Diagnosis of contact dermatitis is often made by presenting symptoms and a thorough history. Usually, the patient will state they have a new exposure to a certain allergen or irritant. To fully diagnose contact allergic dermatitis, patch testing is the gold standard. Patients have several patches applied to their back with common or possible irritants and, after 48 hours, the patches are removed. The health-care provider or allergist then determines the allergy based on the skin test results (Litchman et al., 2023).

Nursing Care of the Patient with Contact Dermatitis

When caring for a patient with contact dermatitis, it is important to obtain a thorough history because this often points to an irritant or allergen. After the patient is diagnosed with contact dermatitis by the health-care provider, the nurse will provide pharmacological and nonpharmacological interventions. Some interventions are identifying the allergen, alleviating itching, and applying topical creams for inflammation and itching.

Recognizing and Analyzing Cues

When recognizing cues, the patient may report recent exposure to a new chemical, irritant, or allergen (e.g., dermatitis develops after wearing latex gloves for the first time). The nurse may look at the affected area and note erythematous and swollen skin. There may also be vesicles or pustules present, and the patient may complain of itching (Litchman et al., 2023). When analyzing these cues and reviewing the patient's history, the nurse may find that the patient had a new exposure to a known or unknown irritant.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Typically, the priority nursing hypothesis for contact dermatitis is impaired skin integrity. The nurse will generate solutions related to impaired skin integrity, starting with eliminating the known or suspected irritant or allergen. The nurse would also apply prescribed topical corticosteroids to the affected area(s). To help with itching, the nurse may administer antihistamines, like cetirizine. If the contact dermatitis is from an allergen, the nurse would anticipate patch testing and potentially apply or assist with applying the patches. The nurse would also instruct the patient to avoid any friction to prevent further irritation to the area and to wear clothing to cover the affected area (Litchman et al., 2023).

Evaluation of Nursing Care for the Patient with Contact Dermatitis

After the nurse has implemented their actions, they will evaluate the effectiveness of the interventions. An expected

outcome would be for the irritant to be identified and the patient's skin to begin to heal and appear less irritated.

Evaluating Outcomes

When evaluating outcomes, the nurse would expect the patient's skin to appear nonerythematous, with no swelling or itching present. The vesicles or pustules should be resolved or in various stages of healing. The nurse should also anticipate the irritant to be identified and the patient to discontinue use of or contact with the known substance.

Medical Therapies and Related Care

Once the irritant or allergen is removed and treatment is initiated, the patient's symptoms will resolve and no further referral is needed. However, if an allergen is suspected, the patient may need to be referred to an allergist for testing. Depending on the severity of the rash, the patient may need a referral to a dermatologist.

Generalized Exfoliative Dermatitis (Erythroderma)

Inflammation of the skin causing erythema and scaling covering 90% of the body's surface area is called **generalized exfoliative dermatitis**, or erythroderma. When severe enough, this condition is life-threatening. Although rare, this skin condition can be caused by many factors, including underlying skin disorders, infection, medications, or malignancy (Austad & Athalye, 2023).

Pathophysiology

The exact pathophysiology of exfoliative dermatitis is not known. Underlying skin conditions, such as psoriasis, atopic dermatitis, and contact dermatitis, seem to be major contributing factors to the development of this disorder. Generalized exfoliative dermatitis is thought to be an inflammatory-mediated response, resulting in rapid epithelial cell turnover (Harper-Kirksey, 2018).

Clinical Manifestations

Clinical manifestations of erythroderma are red patches that appear on the skin, covering 90% of the body. After they appear, the skin starts to scale and flake off. Because this condition affects a large portion of the body skin, it is considered life-threatening, and the patient's condition should be managed in a hospital setting. The patient will also complain of itching and may have a fever, along with an enlarged spleen, liver, and lymph nodes. In some cases, patients lose their hair, and their nails will shed and become ridged (Austad & Athalye, 2023).

Assessment and Diagnostics

When assessing a patient, the nurse will notice diffuse erythematous skin with scaling and peeling. The nurse will obtain a thorough patient history, including information about when the symptoms started. Information about the patient's medications, allergies, present skin conditions, and other related information may be helpful in determining the underlying cause (Harper-Kirksey, 2018). The nurse will also complete any diagnostic tests ordered by the health-care provider, such as a CBC, CMP, ESR, and C-reactive protein (CRP) level.

After completing a thorough history, the nurse can expect the health-care provider to order several diagnostic and laboratory tests. The provider may order a skin biopsy, histology, blood cultures, CBC, CMP, and imaging to help identify the underlying cause. Depending on the underlying condition, the patient may have an elevated WBC count, CRP level, and ESR. The laboratory tests may also show anemia, eosinophilia (excess eosinophils), or other abnormal values. Skin biopsy samples may show mites or other organisms. Imaging, like a chest x-ray, may show malignancies or sarcoidosis, an inflammatory disease in which the immune system overreacts. Blood cultures may reveal infections or viruses (Harper-Kirksey, 2018).

Nursing Care of the Patient with Generalized Exfoliative Dermatitis

When caring for a patient with generalized exfoliative dermatitis, it is important to complete a thorough history of the patient. The nurse must also be aware that this condition is potentially life-threatening and interventions must be provided as ordered.

Recognizing and Analyzing Cues

The patient may report skin itching and may reveal underlying skin conditions like psoriasis or eczema, malignancy, or new medications. The nurse will notice a bright red rash, covering almost the entire body. The patient's skin will flake and peel, even on the palms of the hands and soles of the feet, and they may have hair loss or brittle and ridged nails. When examining the patient's abdomen, the nurse may palpate an enlarged liver or spleen. The nurse may also note lymphadenopathy. When analyzing these cues, the nurse will help the health-care provider by

assessing the patient's skin and then narrow down potential diagnoses based on the laboratory results (Austad & Athalye, 2023).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The priority nursing hypothesis for the nurse is potential hemodynamic stability, because the patient's skin barrier is almost completely absent. The nurse will generate solutions related to maintaining hemodynamic stability and prevent fluid loss. The nurse will provide adequate hydration through IV fluid replacement and replace electrolytes (e.g., potassium, magnesium, calcium) when indicated. The nurse will monitor the patient's hemodynamic status, ensuring the patient's blood pressure and heart rate are within normal limits, and monitor the patient's temperature, providing cooling or warming measures when needed (Harper-Kirksey, 2018).

Another nursing hypothesis related to generalized exfoliative dermatitis is impaired skin integrity. The nurse will provide oral antihistamines (e.g., diphenhydramine) and topical corticosteroids for any itching. The nurse may provide an oatmeal bath and wound care, as needed. Blood cultures may also be needed for identifying bacterial or fungal skin-infection organisms, and nurses can administer antibiotics or antivirals, as ordered, to prevent skin infections (Harper-Kirksey, 2018).

Evaluation of Nursing Care for the Patient with Generalized Exfoliative Dermatitis

After the nurse has generated solutions and taken action related to the nursing hypotheses, they will evaluate outcomes. An expected outcome for a patient with erythroderma is to maintain hemodynamic stability and for the patient's skin disorder to resolve.

Evaluating Outcomes

When evaluating hemodynamic stability and impaired skin integrity, the nurse would expect the patient's vital signs to be within normal limits, without fluid imbalance or electrolyte disturbances, and for the patient's skin to begin healing, with decreased peeling and itching, and eventually heal entirely. The time frame for resolution of symptoms will vary depending on when the underlying cause and any complications. The nurse would also expect the patient's skin to not have any signs of infection and return to a normal appearance (Harper-Kirksey, 2018).

Medical Therapies and Related Care

Because generalized exfoliative dermatitis can be life-threatening, a large interdisciplinary health-care team is needed to properly care for the patient. The nurse can expect collaborative care from a dermatologist (a specialist in skin disorders), an infectious disease specialist, and a pharmacist to help determine underlying etiology. To maintain hemodynamic stability, consultations from a cardiologist and pulmonologist may be indicated. Lastly, if malignancy is found or suspected, an oncologist would collaborate with the health-care team (Austad & Athalye, 2023).

Seborrheic Dermatitis

The skin condition that usually affects the scalp or areas with sebaceous glands, such as the face or areas with skin folds, is called **seborrheic dermatitis**. This condition mainly affects infants and people in middle age but can affect anyone. The noninflammatory type of seborrheic dermatitis is more commonly called dandruff and occurs in adults. In infants, this condition is known as "cradle cap" (Tucker & Masood, 2023).

Pathophysiology

The exact pathophysiology of seborrheic dermatitis is not entirely known. Some theories state that the skin's microbiota becomes disturbed or there is an increase in fatty acids on the skin. Other theories point to a weakened immune system that may allow yeasts to overgrow, or a genetic predisposition to the condition (Tucker & Masood, 2023).

Clinical Manifestations

Clinical manifestations of adult seborrheic dermatitis include itching and burning, usually on the scalp or chin, where hair grows. However, this condition can appear anywhere on the body where sebaceous glands are present. There will be small flakes of skin and, when examining the scalp, there will be light-colored papules with greasy crusts and scales. In infants, seborrheic dermatitis will appear as greasy crusts that can be yellow to brown (Tucker & Masood, 2023)

Assessment and Diagnostics

Diagnosis of seborrheic dermatitis is often made clinically on the basis of the patient's presenting symptoms. In an

adult patient, the nurse will note the clinical manifestations, usually the scalp.

Although routine laboratory tests are not typically ordered to diagnose seborrheic dermatitis, the health-care provider may order them in cases of severe or sudden onset symptoms. Some additional tests may include potassium hydroxide (KOH) skin scraping, histology, HIV testing, antinuclear antibody (ANA), ESR, and several others, although they are not commonly needed (Tucker & Masood, 2023). A positive KOH result can mean a fungal infection has developed. Elevated ANA and ESR results could indicate an underlying autoimmune response or condition.

Nursing Care of the Patient with Seborrheic Dermatitis

When caring for a patient with seborrheic dermatitis, the nurse will recognize and analyze patient cues to create a priority nursing hypothesis. Once they generate a priority hypothesis, the nurse will generate solutions, take action, and then evaluate their interventions.

Recognizing and Analyzing Cues

The nurse will begin by recognizing patient cues for seborrheic dermatitis. The patient may report itching to the scalp, beard area, or another area where many sebaceous glands are present. When examining the affected area, the nurse will note the characteristics of seborrheic dermatitis. In infants, the caregiver may be concerned about the child's scalp and notice yellow to brown crusts.

When analyzing cues, the nurse should ask the patient or caregiver if the patient has any preexisting skin conditions or has had this condition before. The nurse should gather a full medical history for the patient, including any immune disorders like HIV or systemic lupus erythematosus (Tucker & Masood, 2023).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The nurse will prioritize hypotheses based on the patient's cues, generate solutions, and take action. The priority nursing hypothesis for seborrheic dermatitis is impaired skin integrity. When generating solutions and taking action, the nurse can provide both pharmacological and nonpharmacological interventions.

For both infants and adults, the nurse can promote skin care routines that include moisturizing the skin. The nurse can anticipate the health-care provider ordering topical shampoos or creams that contain antifungals combined with anti-inflammatory and anti-itch components, or these medications alone. Many medications for seborrheic dermatitis can be found over the counter; examples are selenium sulfide, ketoconazole, zinc pyrithione, and salicylic acid plus sulfur in sorbelene cream. With infants, the nurse should gently assist with removing the crusts with forceps or saline-soaked gauze before applying creams. The nurse can educate the parents on removing crusts with a loofah or mildly abrasive sponge. In severe cases, oral antifungals such as fluconazole or terbinafine may be prescribed by the health-care provider (Tucker & Masood, 2023).

Evaluation of Nursing Care for the Patient with Seborrheic Dermatitis

After the nurse has implemented the chosen actions, they can evaluate effectiveness. An expected outcome would be for the affected area to present without flaking or crusts.

Evaluating Outcomes

When evaluating outcomes, the nurse would expect the patient's skin to show decreased scaling or flaking, and a decrease in the number in the papules. The adult patient would also report decreased or no itching. In infants, greasy crusts are not present, or are resolving.

Medical Therapies and Related Care

Most cases of seborrheic dermatitis are self-limiting; usually, adult patients will have acute flares. In chronic or severe cases, the patient may be referred to a dermatologist for further evaluation or a pharmacist for special shampoo formularies. In addition, if the patient has any new or underlying medical conditions that may be contributing to the seborrheic dermatitis, they will be referred to the appropriate specialist. For example, the health-care provider may refer a patient to an infectious disease specialist if they have an underlying condition, to an immunologist if they have HIV, or to a rheumatologist if they have an autoimmune disorders like systemic lupus erythematous (Tucker & Masood, 2023).

Pruritus

Itching, or **pruritus**, can occur due to a variety of reasons or underlying medical conditions. Many skin disorders, like atopic dermatitis and psoriasis, present with symptoms of itching. Other diseases, like chronic kidney disease or substance use disorders, can cause pruritus as well (Fazio & Yosipovitch, 2022).

Pathophysiology

Generalized pruritus is a symptom more common in patients over age 65 years, and the pathophysiology is generally unknown. Underlying conditions may contribute to pruritus in the older adult, such as skin disorders like psoriasis or AD, or neurological disorders, like postherpetic neuralgia. Systemic diseases, like Hodgkin's lymphoma, thyroid imbalances, and anemias can also contribute to pruritus. Sometimes dehydration or liver problems can also cause pruritus (Chung et al., 2021).

Clinical Manifestations

The patient will report generalized itching. The nurse may also note reddened or dry and scaly skin. If there are underlying skin conditions present, the nurse may also notice skin lesions indicative of that particular skin disorder (Fazio & Yosipovitch, 2022).

Assessment and Diagnostics

After initial assessment of the skin, the health-care provider will initially order CBC, CMP, ESR, CRP, liver, and thyroid function tests to help determine an underlying cause. The provider may also look for anemias and allergies, or perform HIV testing if there is a suspicion of any of these conditions (Roh et al., 2022). The health-care provider will also complete a thorough medical history and review the patient's list of medications.

Depending on the patient's underlying condition, laboratory values will be different. For instance, if the patient has underlying hypothyroidism, their thyroid function tests would be abnormal, whereas if the patient has iron-deficiency anemia, their blood counts would be abnormal and iron levels would be low.

Nursing Care of the Patient with Pruritus

When caring for a patient with pruritus, it is important to understand the underlying cause. After the patient is diagnosed by the health-care provider, the nurse will provide pharmacological and nonpharmacological interventions.

Recognizing and Analyzing Cues

When recognizing cues, the nurse will assist the health-care provider. The patient will report itching and the nurse may notice the skin is dry, scaling, and red (Fazio & Yosipovitch, 2022). If the nurse recognizes the patient has these symptoms, they may ask the following questions:

- Do you have any known allergies?
- Does anything aggravate the symptoms?
- Have you tried any treatments?
- What is your medical history, or do you have any health conditions?
- What medications are you taking?
- When did the symptoms start?

Prioritizing Hypotheses, Generating Solutions, and Taking Action

When prioritizing hypotheses for pruritus, treating the underlying cause usually takes priority. For example, if the underlying medical condition is hypothyroidism, the nurse would expect the patient to be prescribed levothyroxine. Another priority hypothesis is to impaired skin integrity. The nurse's goal or expected outcome would be to help keep the patient's skin intact.

When generating solutions and taking action, the nurse would promote the use of emollients and moisturizers to help relieve dry skin. The health-care provider may also prescribe topical steroids or oral antihistamines, like diphenhydramine or fexofenadine, to help relieve itching. In patients with chronic kidney disease, ultraviolet light therapy may be ordered. Selective serotonin reuptake inhibitors, like sertraline or fluoxetine, may help with generalized pruritus. The nurse would administer these as indicated or collaborate with other members of the health-care team (Chung et al., 2021).

Evaluation of Nursing Care for the Patient with Pruritus

After the nurse has implemented interventions, they will evaluate effectiveness. An expected outcome is to keep the patient's skin intact. The nurse can assist the health-care provider identify the underlying health condition by collecting specimens for the ordered diagnostic tests.

Evaluating Outcomes

When evaluating the outcome for skin integrity, the nurse would expect the patient's skin to be moist and intact without areas of excoriation, lesions, or signs of infection.

Medical Therapies and Related Care

Depending on the underlying cause, the patient may require care from a collaborative health-care team and internal medicine. If the patient's underlying condition is neurological, the nurse would collaborate with the neurology department. Other specialties might include oncology, pharmacy, infectious disease, nephrology, and psychiatry (Chung et al., 2021).

Acne

Pustules or nodules on the face, neck, and sometimes upper back and arms is called **acne**. It is a very common skin disorder that frequently occurs during the adolescent years from bacteria in the genus *Cutibacterium* (formerly, *Propionibacterium*); however, it can occur at any age. Acne can be caused by medications such as anticonvulsants or steroids, or by endocrine problems such as polycystic ovarian syndrome (PCOS). Genetics and puberty are factors in developing acne as well (Sutaria et al., 2023).

Pathophysiology

Any hormonal changes can contribute to acne. An increase in androgen levels leads to more sebum production in the skin. Acne can also be caused by increased keratinocyte production leading to an increase in sebum. In addition, colonization with the bacteria *C acnes* promotes an inflammatory response of the skin, causing acne to appear. Some foods and cosmetics can trigger acne as well (Sutaria et al., 2023).

Clinical Manifestations

Acne can come in different forms. It may be open or closed, or it can consist of comedones, red papules, pustules, or nodules and cysts (Figure 14.11). A **comedone** is a small bump on the skin that may be flesh-colored, white, or dark. A **papule** is a small, raised bump that is well defined. A **pustule** is a larger acne lesion that contains pus. A **nodule** or **cyst** is a bump that forms below the epidermal layer of the skin; it is filled with keratin and typically lined with squamous epithelium. Patients may report mild pain, swelling, and tenderness at the sites where acne is present.

FIGURE 14.11 Acne is most common during adolescence and can cause cysts and pustules. (credit: "Akne-jugend" by Ellywa assumed (based on copyright claims)./Wikimedia Commons, Public Domain)

Assessment and Diagnostics

Typically, acne is diagnosed by its clinical presentation. The nurse may note comedones, red papules, pustules, or nodules and cysts on the patient's skin. If the health-care provider suspects an underlying contributor, like PCOS or other hormonal disorder, they may order additional laboratory testing, including for follicle-stimulating hormone (FSH), luteinizing hormone (LH), and dehydroepiandrosterone levels (Sutaria et al., 2023). These labs are further discussed in the chapter on reproductive systems.

A diagnosis of acne is often made based on presenting symptoms. In cases of patients with PCOS, the nurse may note an increase in LH and a decline in FSH levels. There may be an increase in androgen levels contributing to acne (Sutaria et al., 2023).

Nursing Care of the Patient with Acne

When caring for a patient with acne, the nurse can provide pharmacological and nonpharmacological interventions, as ordered. Acne is treated on an outpatient basis and usually resolves with treatment.

Recognizing and Analyzing Cues

When recognizing cues, the patient will report areas of redness and tenderness to the face, neck, chest, or upper back. The nurse will observe either comedones, pustules, cysts, or erythematous papules on the patient's skin. When analyzing these cues, the nurse may ask the patient if they have any skin or medical conditions. The nurse should also consider the patient's age and onset of the condition, because hormonal changes can lead to acne, especially in adolescents (Sutaria et al., 2023).

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The priority nursing hypothesis for acne is impaired skin integrity, for which the nurse will generate solutions and take action. With acne, the health-care provider may prescribe topical retinoid (e.g., retinoic acid, tretinoin) or topical gels and lotions (e.g., clindamycin, benzoyl peroxide, azelaic acid) depending on the type of acne. In addition, health-care providers may prescribe oral medications (e.g., doxycycline, spironolactone, isotretinoin) to help control the patient's acne. Oral contraceptives may also be prescribed to address acne in a female patient. The nurse should help administer these medications and teach the patient the importance of daily use and the importance of washing their face. The nurse may also reinforce education about diet changes, like avoiding fatty foods that can trigger acne.

Patients who are prescribed spironolactone need monitoring of their potassium levels because this medication can cause them to increase. The nurse should educate the patient about this requirement, if necessary. The nurse should also teach all patients about medication side effects and when to report them, especially with isotretinoin, because it can lead to serious complications, including birth defects, vision loss, or diabetes (Sutaria et al., 2023).

Evaluation of Nursing Care for the Patient with Acne

After the nurse has implemented their actions, they will evaluate the effectiveness of the interventions. An expected outcome of treatment would be improved appearance of the patient's skin, with less irritation and without signs of acne.

Evaluating Outcomes

When evaluating outcomes, the nurse would expect the patient's skin to appear less irritated and red. Comedones, pustules, cysts, and erythematous papules would be absent or healing. Additionally, the patient would understand the education about face washing, diet, and medication side effects or laboratory values that would need to be monitored.

Medical Therapies and Related Care

Usually, once treatment is initiated the patient's symptoms will resolve and no referral is needed. However, if symptoms continue or worsen, the patient may need a referral to dermatology. If the patient is being treated with isotretinoin, they will need to be closed monitored by a health-care provider for complications, like diabetes or vision loss.

Bacterial Skin Infections

Bacterial skin infections are common. They are usually caused by bacteria that live on the skin, like *Staphylococcus* and *Streptococcus*. Depending on the type and location of the bacterial infection, symptoms may look a little

different (Rehmus, 2023). Two common bacterial infections the nurse will encounter are impetigo and folliculitis.

Impetigo

A bacterial skin infection commonly caused by gram-positive bacteria is called **impetigo**. There are two types of impetigo: bullous impetigo and nonbullous impetigo (Figure 14.12). Bullous impetigo begins with a small vesicle, which then leaks clear to dark fluid. Nonbullous impetigo, the more common type, starts with a small vesicle or pustule that forms and ruptures, causing a honey-colored crust to form. The nurse may provide treatment as ordered by the health-care provider, which usually includes applying topical antibiotics (e.g., mupirocin). Before applying the antibiotic, the nurse should remove the crust and wash the area with soap and water. If the infection worsens, the nurse will alert the health-care provider, and the provider may prescribe an oral antibiotic (e.g., cephalexin, amoxicillin-clavulanate). For children, the nurse would also educate caregivers on the importance of personal hygiene and avoiding contact with other children during treatment, because the infection can easily spread (Nardi & Schaefer, 2022).

(a) (b)

FIGURE 14.12 (A) Bullous impetigo begins with vesicles that leak clear fluid. (B) Nonbullous impetigo occurs when a vesicle ruptures, causing a yellow crust to form. (credit a: CDC/Public Health Image Library, Public Domain; credit b: CDC/ Dr. Thomas F. Sellers; Emory University/ Public Health Image Library, Public Domain)

Folliculitis

Infection and inflammation of a hair follicle are called **folliculitis** (Figure 14.13). It is most commonly caused by bacteria (*Staphylococcus*) but can also be caused by fungi and viruses (e.g., herpes) (Rehmus, 2023). Patients with bacterial folliculitis often present with itching and a mildly erythematous rash. The nurse may also note small pimples or pustules surrounding the hair follicles. Bacterial folliculitis usually resolves on its own without treatment. However, if it worsens, the first-line treatment is topical antibiotics, like clindamycin or mupirocin. If the nurse notes increased redness, swelling, or discharge, the health-care provider may prescribe oral cephalexin or another antibiotic (Winters & Mitchell, 2022).

FIGURE 14.13 Folliculitis is an infection of a hair follicle and can occur anywhere on the body. (credit: "Folliculitis2" by Da pacem Domine/ Wikimedia Commons, CC0 1.0)

Viral Skin Infections

Viruses can cause viral skin infections. Some examples of viruses that can cause skin infections are herpes zoster, COVID-19, human papillomavirus (HPV), and herpes simplex (MedlinePlus, 2023). A nurse must be able to recognize these skin infections and provide appropriate treatment as prescribed by the health-care provider.

Herpes Zoster

Reactivation of the chicken pox virus (varicella zoster) causes a disorder called **herpes zoster** or shingles. Although it can affect anyone at any age, it more commonly affects older adults who likely contracted varicella zoster in childhood, before vaccination was an option. However, chicken pox during childhood is less common now, due to the introduction of the vaccine (Centers for Disease Control and Prevention, 2024). With herpes zoster, patients will typically present with a viral prodrome or feeling unwell and will often have symptoms like fever and a burning sensation where a rash will appear several days later. Once the skin rash develops, it will have a vesicular appearance, follow a dermatome (i.e., areas of skin innervated by a spinal root), and will be unilateral, never crossing the midline (Figure 14.14). Patients will complain of itching and a burning sensation, and pain is often moderate to severe.

FIGURE 14.14 The herpes zoster rash is vesicular, follows a dermatome, and does not cross the midline. (credit: "Shingles Rash" by NIAID/ Flickr, CC BY 2.0)

Once the patient is diagnosed with herpes zoster, the nurse can expect the health-care provider to prescribe oral antivirals (e.g., acyclovir, valacyclovir). The provider may also prescribe antibiotic ointments to prevent the

development of secondary infections. If the nurse notes any lesions on the patient's face, especially near the eye or ear, they should inform the health-care provider immediately. This is because herpes zoster follows the dermatomes and can affect the patient's hearing and eyesight (Nair & Patel, 2023).

Herpes Simplex

There are two types of herpes simplex viruses. The first, **herpes simplex virus type 1 (HSV-1)**, causes vesicular rashes on the skin and face, near the mouth and lips, but it can also occur on the genitalia. The second, **herpes simplex virus type 2 (HSV-2)** is the most common cause of genital herpes (Kaye, 2021).

Patients with HSV-1 or HSV-2 will usually complain of itching and a tingling sensation in the affected area before a vesicular rash appears. When the rash erupts, it appears as small vesicles with an erythematous base. The health-care provider will usually prescribe oral antivirals like valacyclovir or acyclovir for treatment. A viral culture may also be ordered, which the nurse would collect by removing the top portion of the vesicle and swabbing the clear fluid, to determine if the cause is herpes simplex or another virus. Lesions that are near or affect the eye can cause a condition known as keratitis, and the patient should be referred to an ophthalmologist for treatment (Kaye, 2021).

COVID- 19

Although COVID-19 usually causes respiratory symptoms in patients, it can also cause skin manifestations. The most common rash that develops with a COVID-19 skin infection is usually itchy and maculopapular; however, urticarial rashes (e.g., hives), petechiae, and vesicular rashes may also develop on the body. Another prominent manifestation is "COVID toes," which are also known as chilblain lesions. This condition causes the patient's toe(s) to become discolored and inflamed. If a patient who is diagnosed with COVID-19 develops a rash, the nurse should inform the health-care provider so the provider may evaluate the patient. Most skin eruptions associated with COVID-19 are self-limiting and resolve on their own. However, in some cases, the health-care provider may order topical steroids or antibiotics to help open lesions heal or manage symptoms (Singh et al., 2020).

REAL RN STORIES

Nurse: Amanda MSN, FNP-C
Years in Practice: 5
Clinical Setting: Urgent Care
Geographic Location: Nevada

When the COVID-19 pandemic first started, I was working in an urgent care setting as a nurse practitioner. COVID-19 was new, and many patients had different symptoms, including nonrespiratory ones, making it difficult to diagnose. Plus, testing protocols were changing daily due to the lack of in-house testing at the time. Every PCR [polymerase chain reaction] specimen had to be sent to the health department and then to the CDC [Centers for Disease Control and Prevention] for testing.

During this time, I had a patient present with toe redness and tenderness that started a few days prior. He had no other symptoms. His primary care doctor had sent him to urgent care for further workup because they were concerned about a blood clot or other disorder. I ran several blood tests on the patient, which all returned negative. I collaborated with a vascular physician to determine any additional underlying etiology I may have overlooked. When I was taking the patient's history, he had mentioned he may have been exposed to COVID-19 the week prior. When speaking to the vascular physician, he mentioned COVID toes, which had been a potential new finding with COVID-19–positive individuals. We decided to test the patient for COVID-19 and discovered the patient was positive. This was a lesson learned to always complete a thorough history and document it, even if you think it's something irrelevant. You never know where it might lead you or when it will help you diagnose a patient.

Fungal Skin Infections

Fungal skin infections are caused by fungus, yeasts, or dermatophytes. Common organisms are *Candida*, *Microsporum*, and *Epidermophyton*. Fungal infections do not penetrate past the epidermis and usually occur in moist areas, like the feet and genital area. Usually, patients with fungal infections (e.g., candidiasis) will have itching and mild swelling around the affected area. A patient with athlete's foot, or tinea pedis, the patient may present with

itchiness and scaling of the skin. In cases of ringworm, the nurse may notice round patches with a raised border that is scaly and central clearing (Aaron, 2021).

Fungal infections may have slightly different presentations, but treatment is often the same. Treatment usually involves topical or oral antifungals, such as ketoconazole or fluconazole. However, the health-care provider may also order a skin scraping to confirm the diagnosis, and the nurse may need to collect the sample.

Parasitic Skin Infections

Parasitic skin infections are caused by parasites, like protozoa or helminths. Although parasites flourish in areas with inadequate sanitation, they can survive anywhere and usually enter the body through the skin or mouth (Marie & Petri, Jr., 2023). Some examples of common parasitic skin infections that a nurse may encounter are pediculosis and scabies.

Pediculosis

A parasitic skin infection of lice, called **pediculosis**, can affect anywhere there is body hair, including the pubic region. This condition is caused by a tiny insect, a louse, and is extremely transmissible through close contact. In all cases of pediculosis, the patient will present with itching. Upon examination, the nurse may note adult lice or baby lice (nits) on the affected area. For treatment of head lice, the health-care provider will usually order oral ivermectin or topical shampoos like lindane 1%. After shampooing, a fine-toothed comb is used to remove the nits. Pubic lice are typically treated with creams and shampoos, like permethrin or lindane. When lice affect the eyelashes, fluorescein drops are given, or oral ivermectin.

The nurse also should educate the patient to inform any sexual partners or those with whom they have had in close contact; these people would need to be treated as well. The nurse also instructs the patient to clean towels and bedding in hot water and to not share any personal items like hairbrushes or towels until they are sanitized and clean (Dinulos, 2021).

FIGURE 14.15 When looking at a patient's hair sometimes you can see tiny nits, which are baby lice. (credit: "Head Infested With Louse" by Aditya Suseno/Wikimedia Commons, CC0 1.0)

Scabies

The parasitic skin infection caused by a mite that usually affects the spaces between the fingers, wrists, axillae, and abdomen along the belt line is called **scabies**. Patients with scabies will report intense itching that is usually worse at night. When examining the patient with the health-care provider, the nurse may notice erythematous papules with small scaly lines or burrows. For treatment, the health-care provider will order topical treatments like permethrin or may prescribe oral ivermectin. When caring for the patient, the nurse should follow contact precautions and wear proper personal protective equipment because scabies can be easily transmitted (Dinulos, 2021).

Benign Tumors

Benign tumors are those that are noncancerous and can grow anywhere on the skin. Common types of benign tumors are cysts, angiomas, keloids, moles, warts, and dermatofibromas. As a nurse, you will encounter many benign tumors; it is important to recognize their appearance, symptoms, and recommended treatment options from the health-care provider.

Cysts

Cysts can appear anywhere on the body. If a patient has a cyst, the nurse may note a small mass or nodule that is hard and nonfluctuant. Rarely, cysts can become infected, and the nurse would note redness, swelling, and potential discharge around the site. If the cyst is large enough or bothersome to the patient, the provider can surgically remove it. Depending on its appearance, the provider may order a biopsy to determine the exact etiology. After the cyst is removed, the nurse would educate the patient on signs and symptoms of infection at the incision site and to avoid strenuous activity for 7 to 10 days after the procedure to prevent infection and maximize skin healing (Zito & Scharf, 2023).

Angiomas

Another type of benign tumor is an **angioma**, which is a small collection of blood vessels or lymphatic tissue. There are different types of angiomas (e.g., cherry hemangiomas), and they can occur anywhere on the body. In patients with cherry angiomas, the nurse may note a red, dome-shaped area (Figure 14.16). Trauma to an angioma typically causes it to bleed. To determine the depth of larger angiomas, the health-care provider may order imaging, like tomography, before determining if the angioma can be removed. Removal can be done by electrocauterization, cryotherapy, or laser treatment (Qadeer et al., 2023).

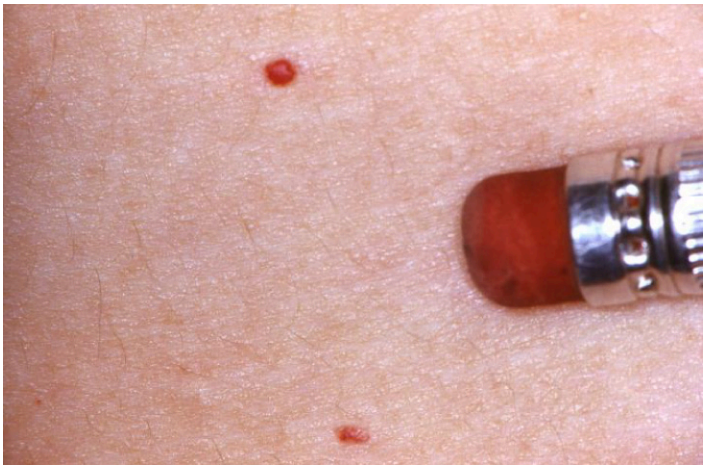

FIGURE 14.16 This patient has a cherry hemangioma, which results from a small collection of blood vessels. (credit: "ID# 17608" by CDC/Dr. F. Gilbert/Public Health Image Library, Public Domain)

Keloids

A **keloid** is a firm and rubbery area of skin that can appear flesh-colored or hyperpigmented. It can appear as a response to skin inflammation that causes abnormal wound healing and increased skin cell proliferation or hypertrophy. Treatment methods include topical corticosteroids and compression devices to reduce keloid development while wounds are healing. Some patients require more extensive care to remove keloids, including cryotherapy, surgical excision, and laser treatment; the nurse can help coordinate care for these procedures (McGinty & Siddiqui, 2022).

Pigmented Nevi (Moles)

A **pigmented nevus** or **melanocytic nevus**, also called a mole, is a macule or papule on the skin. Moles can range in color from the patient's skin tone to a deep brown. Because moles can resemble skin cancer (specifically, melanoma), the provider will assess the mole for asymmetry, irregular borders, color, diameter, and changes to determine if the area is concerning. If any issues are present, the nurse would anticipate the provider to order a skin biopsy. The provider may also remove the mole completely for histology or for cosmetic reasons (Aaron, 2022).

Verrucae (Warts)

A **verruca**, or a wart, is a lesion caused by the human papillomavirus (HPV) that is generally flesh-colored, raised, with an irregular surface and can occur anywhere on the skin, including the soles of the feet and palms of the hands. Human papillomavirus causes warts, and warts do not generally cause any symptoms. However, plantar warts that occur on the bottom of the feet can become painful due to friction.

After diagnosis, treatment depends on the size of the warts. Methods might include observation (many warts resolve on their own within 24 months), topical salicylic acid, retinoic acid, or cryotherapy. Verrucae are sometimes biopsied to determine the exact etiology, and the nurse may anticipate the provider ordering a biopsy procedure (Al Aboud & Nigam, 2023).

Dermatofibroma

A **dermatofibroma**, also called a benign fibrous histiocytoma, is a small, benign papule made of fibroblastic tissue (the skin's connective tissue) and can range in color from red to brown. Patients may complain about itching in the area, but this is not common. Because dermatofibromas can resemble forms of skin cancer, biopsies are often performed by the health-care provider to confirm diagnosis. For treatment, the nurse can expect the provider recommend surgical excision or cryotherapy (Aaron, 2022).

Malignant Tumors

Malignant tumors are cancerous and can form anywhere on the skin. Common types of malignant tumors are melanoma, basal cell carcinoma, and squamous cell carcinoma. As a nurse, you may encounter malignant tumors; it is important to recognize their appearance and be knowledgeable about recommended treatment options from the health-care provider.

Basal Cell and Squamous Cell Carcinoma

The most common form of skin cancer, **basal cell carcinoma**, arises from the lowest layer (basal) of the epidermis. The condition may appear as patches of shiny pink skin to clear bumps that sometimes break open and form a scab. The nurse can expect the health-care provider to order a biopsy of the lesion to confirm the diagnosis of basal cell carcinoma. Treatment involves removal by cauterization, cryosurgery, excision, or Mohs surgery. During Mohs surgery, the provider removes small portions of the lesion and views them under a microscope to determine if the borders have been completely removed (Wells, 2022).

Another form of skin cancer, **squamous cell carcinoma** originates from the squamous layer of skin and may be preceded by actinic keratosis. When inspecting the patient's skin, the nurse may notice irregular, scaly, and thickened growths that do not heal. As with basal cell carcinoma, the nurse would anticipate a skin biopsy to be ordered to confirm the diagnosis. The lesion will then be removed using the same techniques as for basal cell carcinoma. After the carcinoma is removed, the nurse can reinforce prevention measures, like avoiding sunlight, using sunscreen, and wearing long-sleeved clothes while outdoors (Wells, 2022).

Melanoma

Another form of skin cancer, **melanoma** arises from melanocytes and can appear flat or raised and vary in color, including red, brown, black, or blue (Figure 14.16). Lesions often appear in areas where the skin is exposed to sunlight. The main treatment is removal; the health-care provider will biopsy the lesion to confirm the diagnosis. Because melanoma is an aggressive form of skin cancer and can spread to other parts of the body, adjunct therapies like cryotherapy, radiation, and immunotherapy may also be ordered.

FIGURE 14.17 Melanoma is a form of skin cancer. Notice its irregular border and color, which can be indicative of skin cancer. (credit: "Melanoma"/National Cancer Institute, Public Domain)

Nurses should also reinforce education by instructing patients about skin cancer prevention and the ABCDEs of melanoma. The ABDCEs of melanoma or any skin cancer are:

- A = Asymmetry: Is the lesion asymmetrical?
- B = Borders: Are the borders irregular?
- C = Color: Are there changes in skin color or has the skin become significantly darker?
- D = Diameter: Is the lesion greater than one-quarter of an inch?
- E = Evolution: Has the mole changed?

Answering yes to any of these ABCDEs may indicate the patient potentially has a form of skin cancer (Wells, 2022).

Cutaneous Procedures and Treatment

Benign and malignant skin lesions and tumors are often removed via cutaneous procedures or treatment. Some common cutaneous treatments are laser treatment, cosmetic procedures, and wound flaps or grafts.

Laser Treatment of Lesions

Laser treatment of skin lesions involves using laser light therapy. The skin absorbs laser light, and the affected skin cells repair and heal themselves. Laser treatments are used most commonly on pigmented skin or nevi but can also be used on vascular abnormalities, angiomas, granulomas, and other skin conditions. During this procedure, patients and anyone on the health-care team must wear safety goggles and eye shields to protect themselves from the laser light. The patient should also receive local anesthesia to the area through topical agents like 4% lidocaine. After the laser treatment, the nurse should provide skin-cooling measures (e.g., ice packs) to the treatment area. The nurse should also instruct the patient to avoid sunlight exposure to the area for a certain amount of time (Gaffey & Johnson, 2022).

Cosmetic Procedures

Depending on the type of skin lesion or tumor, the health-care provider may order cosmetic procedures like facial reconstruction or dermabrasion. Facial reconstruction is plastic surgery on the face that is often performed after skin cancer lesions removal or after Mohs surgery. After facial reconstruction, the nurse would administer pain medications and provide wound care as ordered. The nurse may also apply topical antibiotics to the surgical incision to promote wound healing (Cottrell & Raggio, 2023).

Dermabrasion is resurfacing the skin; it promotes remodeling and wound healing by using abrasive materials. This process is often used to treat actinic keratosis and acne scars but can also be used for scar revisions and after Mohs surgery. During the procedure, the nurse may apply local anesthesia ointments (e.g., lidocaine) to help relieve pain

and may assist the health-care provider with holding the skin taught. After the procedure, the health-care provider may order saline-soaked gauze or an occlusive ointment, like petroleum, to promote skin healing (Bedford & Daveluy, 2023).

Wound Coverage with Flaps and Grafts

Skin flaps and skin grafts are two common types of skin closure and wound coverage techniques. A **skin flap** is created when healthy skin is only partially detached to cover a nearby wound, whereas a **skin graft** involves transferring skin and related blood vessels from one area of the body to another and is used to cover larger wounds. Skin flaps are often the preferred closure technique because the flaps have an adequate vascular supply.

Skin flaps and grafts are often used to close areas where skin cancers or large tumors have been removed, often after surgical excision or Mohs surgery (Prohaska et al., 2022). After a skin flap or graft procedure is performed, the nurse would perform wound care as ordered and assess the site for signs and symptoms of infection. They would also administer pain medication as needed. The nurse can also reinforce postprocedure patient education, such as limiting contact with water at the site of the procedure or avoiding strenuous activity, because it can cause the wound to stretch. Wash your hands thoroughly before changing a dressing, to prevent possible spread of bacteria. If the patient has a vacuum dressing, make sure the tubing is attached and correct pressure is set, because this promotes wound healing and removes excess moisture from the wound bed (Hoss, 2022).

Summary

14.1 Integumentary Disorders

- The skin has three major layers: the dermis, epidermis, and hypodermis. Each layer serves a particular function regarding the integumentary system.
- Atopic dermatitis (eczema) occurs when a person has a dysfunctional skin barrier, allowing the body to be more susceptible to pathogens. Atopic dermatitis is linked to genetics, the immune system, and epidermal dysfunction. Symptoms are itching, skin redness and dry patches, and skin thickening.
- Psoriasis is the proliferation of skin cells and chronic skin inflammation. The most common is plaque psoriasis. This autoimmune disorder is linked to several genes and is inheritable. Symptoms include itching and well-defined thick patches of reddened skin with a silver scale appearance.
- Atopic dermatitis and psoriasis are diagnosed by clinical presentation and symptoms. A skin biopsy specimen can be taken, if necessary. Additional blood tests for psoriasis may be ordered and include a CBC, renal and liver function panels, ESR, rheumatoid factor level, and others.
- The priority nursing diagnosis for AD and psoriasis is impaired skin integrity. Nurses should monitor for signs of infection and promote pharmacological and nonpharmacological interventions, such as topical medications and, when indicated, systemic medications. If the patient was administered immunosuppressants, the nurse would monitor for signs of serious infection and for renal and liver function.
- When evaluating outcomes, the desired outcome is no signs and symptoms of infection. The nurse would evaluate the patient's compliance with medications and treatment. If the patient was administered immunosuppressants, the nurse would expect no serious infections and for renal and liver function to remain normal.
- For patients with AD, the nurse would promote referrals to a dermatologist, wound care specialist, and an allergist, if needed.
- For patients with psoriasis, the nurse would encourage referrals to a dermatologist, wound care specialist, and an allergist. Additional referrals to a nephrologist, ophthalmologist, or rheumatologist may be needed, depending on the type and severity of psoriasis.

14.2 Burns

- Depending on the degree of severity, a burn can destroy the epidermal and dermal layers of the skin. A burn causes protein denaturation and damage to collagen. After a burn injury occurs, three zones of injury arise: the zones of coagulation, statis, and hyperemia.
- The type of burn injury a patient has is based on appearance. First-degree burns are pink to red and brown, and dry; second-degree burns are moist and blistering; and third-degree burns are dry, leathery, and white or brown/black.
- The priority nursing hypothesis for most burn injuries is impaired skin integrity. Nurses will provide supportive measures such as wound care, infection prevention, pain control, fluid resuscitation, and airway management as needed.
- When evaluating the effectiveness of nursing care, the nurse would expect wound healing within the typical healing time with no signs of infection. The nurse should expect the patient's pain to be tolerable.
- Patients with burn injuries require interdisciplinary care that can include wound care specialists, dermatologists, nutritionists, infectious disease specialists, and plastic surgeons. Additional care from other specialists may be required depending on smoke inhalation or conditions such as SJS and TENS, including pulmonologists, intensivists, and others health-care professionals.

14.3 Dermatologic Conditions

- Depending on the patient's skin condition, pathophysiology, risk factors, and clinical manifestations will differ. Pathophysiology typically involves a disruption of the skin barrier and an inflammatory response. Risk factors can be related to underlying health conditions, age, and exposure. Usually, patients with skin conditions will present with itching, erythema, and skin lesions.
- Diagnostic and laboratory values will vary depending on the patient's dermatological condition. Most skin conditions are diagnosed by clinical presentation and do not require additional diagnostic tests. However, some skin conditions may have underlying contributors, so the health-care provider will order tests

accordingly.

- For most dermatological conditions, the priority nursing diagnosis is impaired skin integrity. In some cases, the priority is to treat the underlying condition or remove the agent causing the rash first. Nurses will provide pharmacological and nonpharmacological interventions and may administer medications and monitor laboratory values as ordered by the health-care provider.
- When evaluating the effectiveness of nursing care, the nurse will expect optimal skin integrity as an outcome in most cases. The skin will appear normal or healing and without signs of infection.
- Depending on the underlying cause of the skin condition, the nurse can promote medical therapies and collaborative care. Patients may require referrals to various specialists, depending on the severity and specifics of the condition.

Key Terms

acne pustules or nodules on the face, neck, and sometimes upper back and arms
angioma small collection of either blood vessels or lymphatic tissue
atopic dermatitis chronic skin condition in which a person has a dysfunctional skin barrier that allows substances outside to penetrate the skin easily, causing dry and red areas of skin
basal cell carcinoma most common form of skin cancer; arises from the basal layer of the epidermis
burn injury to the skin from heat or chemicals
chemical burn burn that occurs from chemicals, like acids or strong detergents
comedone small bump on the skin that may be flesh-colored, white, or dark
contact dermatitis inflammation of the skin caused by direct contact with an irritant or allergens
cyst (also: **nodule**) bump that forms below the epidermal layer of the skin that is filled with keratin and is usually lined with squamous epithelium
debridement removal of damaged tissue around a wound to allow for new tissue to grow more easily
dermatitis inflammation or irritation of the skin
dermatofibroma (also: *benign fibrous histiocytoma*) small, benign papule made of fibroblastic tissue; can range in color from red to brown
dermis middle layer of the skin, just below the epidermis, made up of connective tissue that supports the epidermis
electrical burn burn that occurs from exposure to electricity or electrical currents
epidermal hyperplasia thickening of the epidermis
epidermis outermost layer of skin, made of epithelial cells
erythematous abnormal redness of the skin, often caused by a rash or skin irritation
eschar piece of dead tissue that is cast off from the surface of the skin, particularly after a burn injury
excoriation areas of skin that are broken from scratching and that may bleed or ooze in severe cases
exocrine gland gland that secretes substances through ducts onto the skin's epithelial surface instead of the bloodstream
first-degree burn superficial burn, only affecting the epidermis; appears pink to red and dry
folliculitis infection and inflammation of a hair follicle
generalized exfoliative dermatitis (also: *erythroderma*) inflammation of the skin causing erythema and scaling covering 90% of the body's surface area; when severe enough, is life-threatening
herpes simplex virus type 1 (HSV-1) virus that causes vesicular rashes on the skin and face, near the mouth and lips, but it can also occur on the genitalia
herpes simplex virus type 2 (HSV-2) virus that is the most common cause of genital herpes
herpes zoster (also: *shingles*) virus that is caused by reactivation of the chicken pox virus (varicella zoster)
hypodermis (also: *subcutaneous tissue*) bottom layer of skin that is made of adipose and areolar tissue that cushions the underlying organs
impetigo bacterial skin infection commonly caused by gram-positive bacteria
integumentary system largest organ of the body, comprising skin, hair, and nails
keloid firm and rubbery area of skin that can appear flesh-colored or hyperpigmented
keratin skin protein that makes up hair and nails
lichenification skin thickening over time in an area that is frequently scratched
melanocytic nevus (also: **pigmented nevus** or *mole*) macule or papule on the skin

melanoma form of skin cancer that arises from melanocytes; can appear flat or raised and vary in color, including red, brown, black, or blue
nodule (also: **cyst**) bump that forms below the epidermal layer of the skin that is filled with keratin and is usually lined with squamous epithelium
onycholysis nail separation from the nail bed
papule small, raised bump that is well defined
parakeratosis when the skin's keratinocytes do not completely mature
pediculosis parasitic skin infection of lice
phototherapy ultraviolet light exposure to the skin
pigmented nevus (also: **melanocytic nevus** or *mole*) macule or papule on the skin
plaque raised lesion on the skin
pruritus itching
psoriasis chronic dermatological disorder, characterized by the proliferation of skin cells and chronic inflammation.
pustule larger acne lesion that contains pus
radiation burn burn that occurs from exposure to radiation sources, such as sunlight or machines that emit radiation during some cancer treatments
scabies parasitic skin infection caused by a mite; usually affects the spaces between the fingers, wrists, axillae, and abdomen along the belt line
seborrheic dermatitis skin condition that usually affects the scalp or areas with sebaceous glands, such as the face or areas with skin folds
sebum oil produced by the sebaceous glands to keep the skin moisturized
second-degree burn partial-thickness burn affecting the epidermis and part of the dermis; appears as red and blistering and can be very painful
skin flap healthy tissue moved to a nearby wound to help with healing
skin graft surgical procedure in which healthy skin tissue is taken from one part of the body and moved to another that has a wound
squamous cell carcinoma skin cancer that originates from the squamous layer of skin
Stevens-Johnson Syndrome (SJS) abrupt, rare skin reaction usually caused by medications; involves loss of skin and sometimes mucosal membranes
thermal burn burn caused by an external heat source, like flames, steam, or hot liquids
third-degree burn full-thickness burn affecting the entire epidermis and dermis and extending into subcutaneous tissue; appears white or black, dry, and leathery
toxic epidermal necrolysis (TEN) abrupt, rare skin reaction usually caused by medications; involves loss of skin and sometimes mucosal membranes
verruca (also: *wart*) lesion caused by the human papillomavirus that is generally flesh-colored, raised, with an irregular surface and can occur anywhere on the skin, including the soles of the feet and palms of the hands
zone of coagulation central area of a burn where tissue has been irreversibly damaged and coagulated
zone of hyperemia outermost area of a burn where tissue is inflamed and has increased blood flow, typically recovering without intervention.
zone of stasis area surrounding a burn where the tissue has decreased perfusion but the skin is still potentially viable

Assessments

Review Questions

1. What is a risk factor for developing atopic dermatitis? Select all that apply.
   a. family history of atopic dermatitis
   b. history of asthma
   c. taking antihistamines
   d. recent contact with an irritant, such as poison oak

2. A nurse is caring for a patient with plaque psoriasis. What intervention is the priority for this patient?

a. Ask for a referral to an allergist for skin testing.
b. Promote showering daily with hot water.
c. Educate the patient on stress-reduction techniques.
d. Apply daily topical antibiotics.

3. A nurse is assessing a patient with a second-degree burn. What would the nurse expect the wound to look like?
a. dry and leathery
b. black and moist
c. wet and blistering
d. dry and pink

4. A patient has sustained a burn while using paint thinner. What is the most likely source of the burn?
a. thermal
b. radiation
c. electrical
d. chemical

5. You are caring for a patient with third-degree burns covering 50% of their body sustained during a house fire. What would be a priority intervention for this patient?
a. control pain before wound care
b. skin to begin healing with wound care
c. oxygen support
d. check for signs of infection

6. What virus causes shingles?
a. herpes simplex virus
b. varicella zoster
c. human papillomavirus
d. herpes zoster

7. Actinic keratosis is a precursor to what skin disease?
a. melanoma
b. basal cell carcinoma
c. squamous cell carcinoma
d. angioma

8. What is a description of a rash caused by herpes zoster?
a. vesicular rash, not crossing the midline
b. maculopapular, not crossing the midline
c. pustular, following a dermatome
d. macular, following a dermatome

9. What clinical manifestations would an infant have with seborrheic dermatitis?
a. vesicular rash on the head
b. greasy, crusting appearing rash
c. maculopapular rash on the skin folds
d. pustular rash surrounding the hair follicles

10. What skin condition is caused by a parasite?
a. scabies
b. dermatofibromas
c. verrucae

d. pruritus

Check Your Understanding Questions

1. Explain the diagnostic and laboratory tests required to diagnose atopic dermatitis.
2. You are caring for a patient with TENS. What diagnostic tests might be ordered for this patient? What laboratory values might be abnormal?
3. Explain medical therapies a patient with SJS may need during the rehabilitation phase of care.
4. How do the pathophysiological changes seen in burn injuries influence the choice of medical and nursing interventions?
5. When caring for a patient with generalized exfoliative dermatitis, which diagnostic tests and laboratory values might you expect?
6. What medical therapies might a nurse implement when caring for a patient with contact dermatitis?

Reflection Questions

1. After providing wound care and dressing changes for a patient with second-degree burns, what indicators would the nurse use to evaluate the efficacy of the nursing care provided?
2. What medical therapies might the nurse anticipate for the treatment of a patient with extensive third-degree burns, and how do these therapies support recovery?
3. A patient presents to the clinic with pruritus. What interventions and outcomes might the nurse expect for this patient?

What Should the Nurse Do?

Sarah, a 45-year-old female, presents to the dermatology clinic with complaints of persistent itching and rash on her lower legs for the past 2 weeks. She reports a history of atopic dermatitis and seasonal allergies. On examination, Sarah's lower legs exhibit erythematous, raised, and scaly patches with excoriation marks due to scratching. Her vital signs are within normal limits. Sarah mentions she has tried over-the-counter hydrocortisone cream without relief. Further assessment reveals no signs of infection or systemic illness. Sarah expresses frustration and discomfort due to the persistent symptoms affecting her daily life.

1. What specific cues from Sarah's medical history and presenting symptoms suggest a potential exacerbation of her underlying eczema rather than an unrelated dermatological condition?
2. What nursing interventions and patient education strategies would be appropriate to address Sarah's symptoms and improve her management of atopic dermatitis?

Ms. Jones, a 45-year-old female, presents to the emergency department after sustaining burns from a kitchen accident at home. She reports experiencing intense pain and redness over her left forearm and hand. Ms. Jones has no significant past medical history except for mild hypertension, for which she takes amlodipine. On assessment, her vital signs are as follows: heart rate 110 bpm, blood pressure 140/90 mmHg, respiratory rate 20 breaths per minute, and temperature 38.5°C (101.3°F). There are partial-thickness burns covering approximately 15% of her total body surface area, concentrated on the left upper extremity. She is also visibly distressed and anxious.

3. Given Ms. Jones's symptoms and vital signs, what are the primary concerns regarding her burn injury management?
4. What nursing interventions can be implemented to address Ms. Jones's pain and anxiety?
5. When caring for a patient with impetigo, what nursing interventions might you implement?

Competency-Based Assessments

1. A nurse is caring for a patient who is taking methotrexate for plaque psoriasis. Their laboratory test values returned today and showed elevated AST and ALT levels and white blood cell (WBC) count. What interventions might this nurse implement and what other laboratory tests might this nurse want to monitor?

2. As a clinical nurse, what strategies can you use to evaluate the efficacy of care provided to patients with integumentary disorders?
3. How do nurses incorporate knowledge of medical therapies into the management of integumentary disorders?
4. You are caring for a patient with a burn injury. What strategies can you implement to ensure infection prevention while caring for this patient?
5. Explain the rationale behind ordering specific diagnostic tests and interpreting laboratory values for patients with burns. How do these assessments help determine the severity of burns and guide treatment decisions?
6. When working with a patient, how would you identify the pathophysiological mechanisms underlying psoriasis and eczema? How do these conditions differ in terms of their etiology and inflammatory pathways?
7. Interpret the significance of elevated eosinophil counts in a patient presenting with dermatitis. How might this finding guide the diagnostic process?

CHAPTER 15

Cerebrovascular System

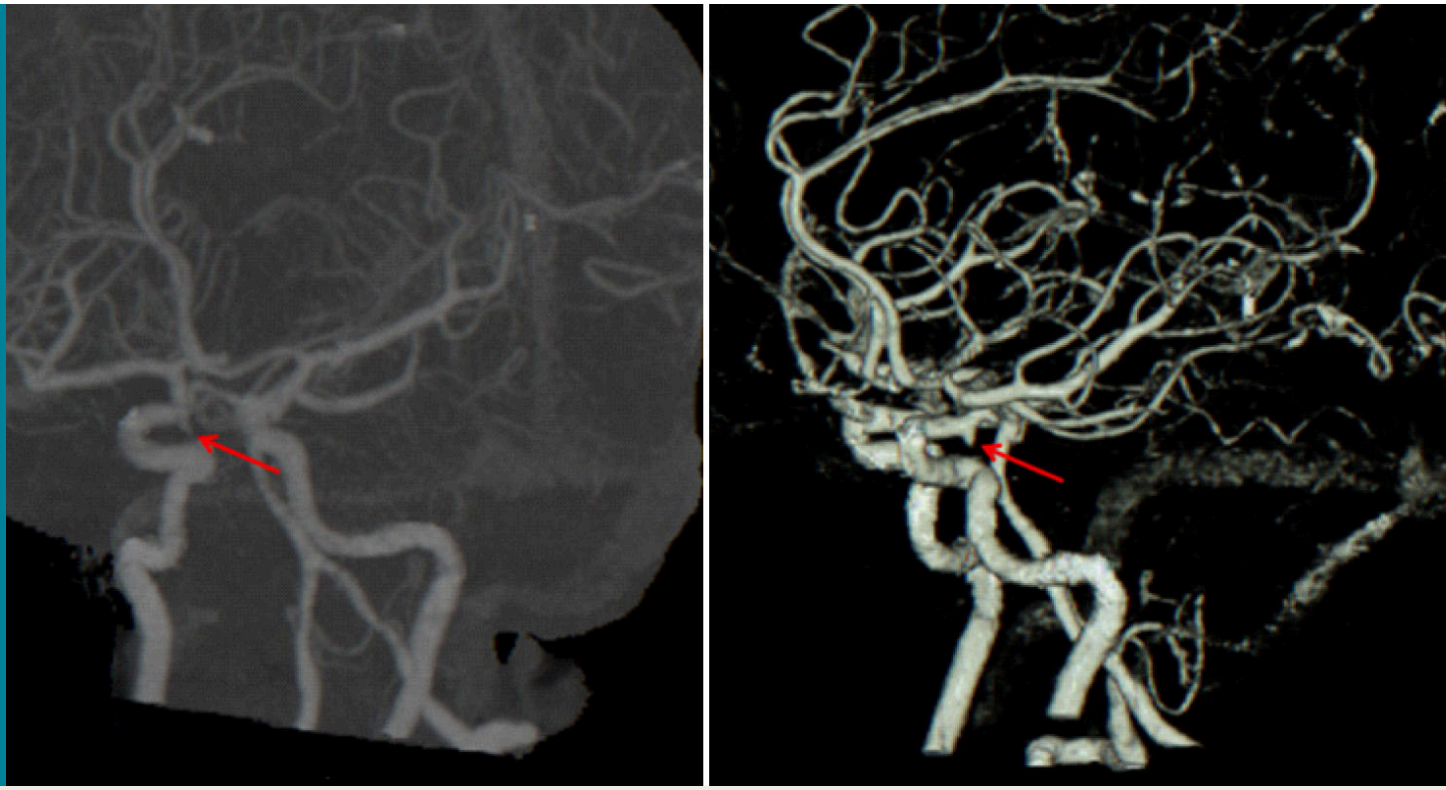

FIGURE 15.1 Computed tomography angiography can give an effective visualization of the cerebral vasculature, such as the aneurysm indicated by the red arrows. (credit: "Volume_rendered_CT_angiography_of_posterior_communicating_artery_aneurysm.png" by Shazia Mirza and Sankalp Gokhale/Wikimedia Commons, CC BY 4.0)

CHAPTER OUTLINE

INTRODUCTION The brain is one component of the central nervous system (CNS). This crucial organ controls or interprets everything we do: our movement, breath, emotional reactions, vision, experience of hot and cold. The brain's functioning requires a continuous supply of glucose and oxygen; consequently, its vasculature is complex. However, what if there is a disruption in the perfusion of the brain? What happens when the brain cells, which control our every voluntary and involuntary movement, do not receive the oxygen and nutrients they need to function? The result is a stroke.

Treating patients who have had a stroke—or cerebrovascular accident (CVA), as strokes are commonly called—is quite complex. It requires an understanding of the cerebral vasculature and the brain. There are two distinct types of strokes: ischemic and hemorrhagic. Differentiating the two will help guide nursing care to recognize cues, prioritize interventions, and evaluate outcomes.

15.1 The Cerebrovascular System and Cerebral Vascular Accidents

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the anatomy of the brain
- Explain how the areas of the brain are perfused by the circle of Willis
- Discuss the recognition and emergency treatment of cerebrovascular accidents

The cerebrovascular system includes the brain and the vessels that supply and circulate blood within the brain. The brain is a very active organ, and adequate perfusion is necessary to support brain function. In fact, the brain receives between 15 percent and 20 percent of the resting cardiac output of the heart (Hickey & Strayer, 2020). A disruption in the blood supply to the brain—that is, a stroke—can have catastrophic results; a lack of perfusion in an area of the brain can cause irreversible damage to the tissue in minutes. Time is of the essence in responding to such an insult to the brain's tissues, as prompt treatments and procedures can restore perfusion and lessen the severity of or completely eliminate cellular damage.

Stroke is the fifth-leading cause of death and the leading cause of disability in the United States (American Stroke Association, 2023); worldwide, it is the leading cause of acquired, permanent disability (Grefkes & Fink, 2020). Although the treatment of acute strokes has improved considerably, the majority of patients will still have lasting disabilities. Many patients are left with considerable impact on functional independence and quality of life. Early recognition and treatment of a stroke can save a person's functionality and even their life.

Review of Brain Anatomy

The human brain, although about only 2 percent of the body's weight, is the most complex organ. The brain processes and controls information, allowing for movement, memory, sensation, behavior, language, balance, and much more. It is necessary to first appreciate the anatomic structure of the brain to understand how a stroke can impact the brain and impair functionality.

Areas of the Brain

The structure of the brain itself can be broken down into three main areas: the cerebrum, the brainstem, and the cerebellum. These areas contain multiple structures that work in concert to control almost every aspect of life. The cranial nerves are a critical component of the **central nervous system (CNS)**, the body's processing and functional control center; they transfer motor and sensory information between the brain and different areas of the face and trunk. It is imperative for the nurse to understand the structure and function of the brain to allow for early recognition of cues for impaired function.

The Cerebrum

The cerebrum is comprised of the left and right cerebral hemispheres (Figure 15.2). The hemispheres are mirror images of each other, each containing half of the frontal, parietal, temporal, and occipital lobes.

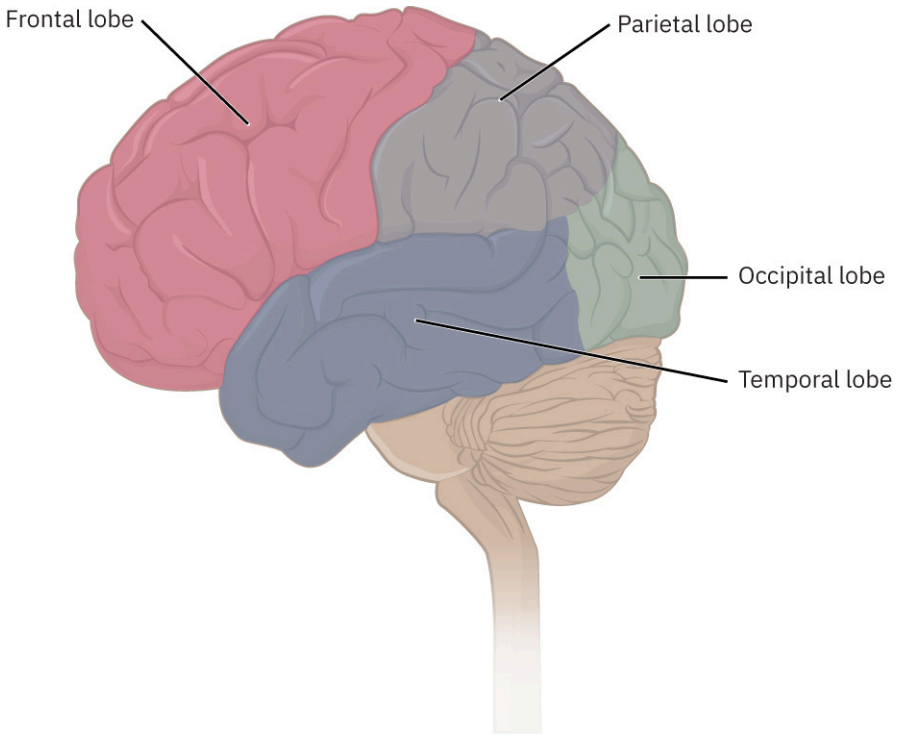

FIGURE 15.2 The four lobes of the cerebrum are the frontal, parietal, temporal, and occipital. (credit: modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The frontal lobe, the largest area of the brain, found at the front of the cerebrum, is responsible for many higher-level functions such as:

- reasoning
- abstract thought
- executive function
- concentration
- information storage for memory
- personality
- inhibition
- judgment

Also under the control of the frontal lobe is some voluntary motor function, particularly that of speech (e.g., Broca's area). The frontal lobe contains a motor strip that controls the motor coordination of the corresponding parts of the body (Figure 15.3). Finally, the frontal lobe plays a role in the involuntary functions of respiration, gastrointestinal movement, and blood pressure.

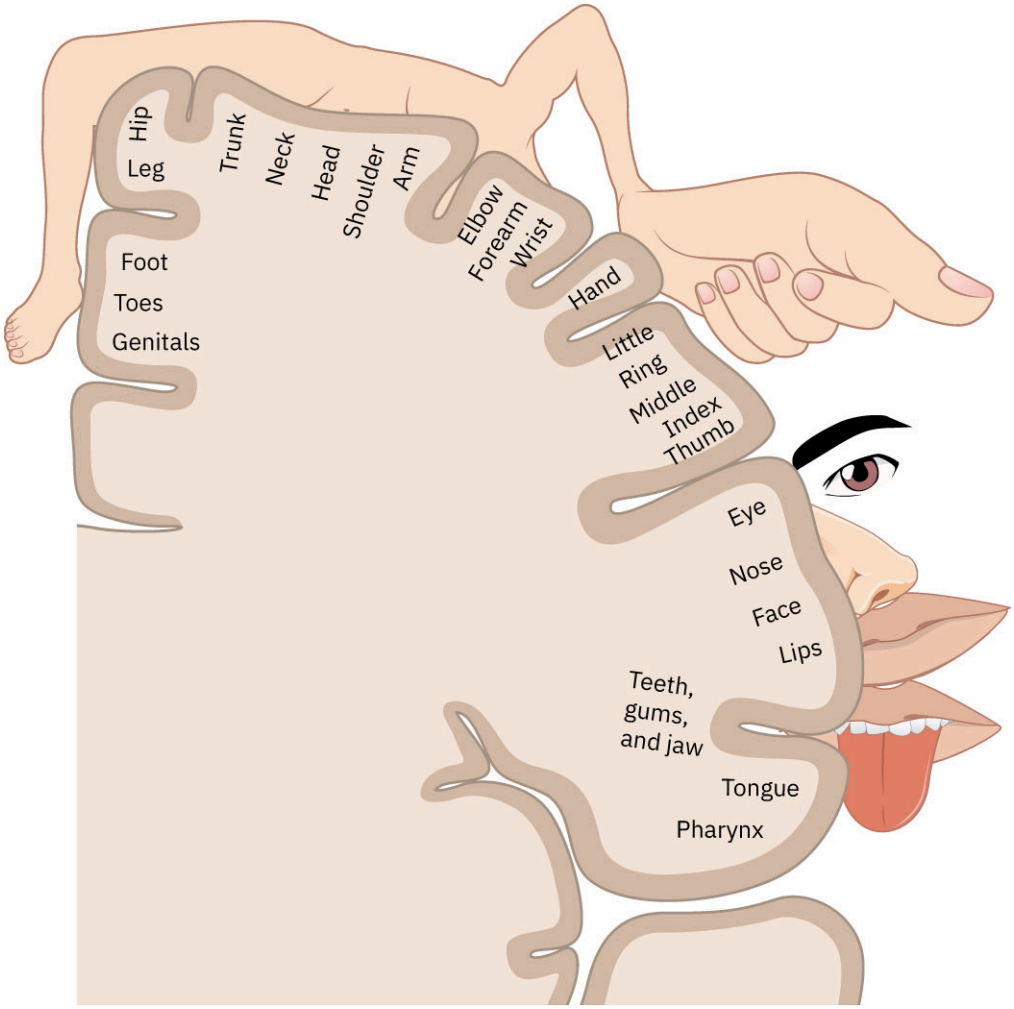

FIGURE 15.3 This image illustrates the motor strip of the frontal lobe and the corresponding areas of the body over which it has control. (credit: modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The parietal lobe houses the sensory cortex and is responsible for sensory recognition in the same areas as the motor strip. Sensory awareness consists of touch, pressure, vibration, and a person's **proprioception**, or awareness of their own body position and movement in relation to the space around them.

The temporal lobe is primarily for auditory association. It is important for memory and language interpretation. This lobe also houses Wernicke's area, which encompasses the auditory cortex on the lateral sulcus. Past experiences with music, art, conversation, and taste are stored here. The temporal lobe is responsible for multi-modal sensory integration.

Last, the occipital lobe is where visual perception, interpretation, and memory take place. The occipital lobe also has a role in visual reflexes and smooth eye movement.

The thalamus, hypothalamus, and pituitary area are housed deep within the cerebrum. They are key players in vital functions such as the stress response, thermal regulation, hormone regulation, sleep-wake cycle, emotional response, blood pressure regulation, appetite control, and general control of the autonomic nervous system.

The Brainstem

The brainstem comprises the midbrain, pons, and medulla (Figure 15.4). The midbrain coordinates sensory representations of the visual, auditory, and somatosensory perceptual spaces. The pons is the main connection with the cerebellum. The pons and the medulla regulate several crucial functions, including heart rate and respiratory rate.

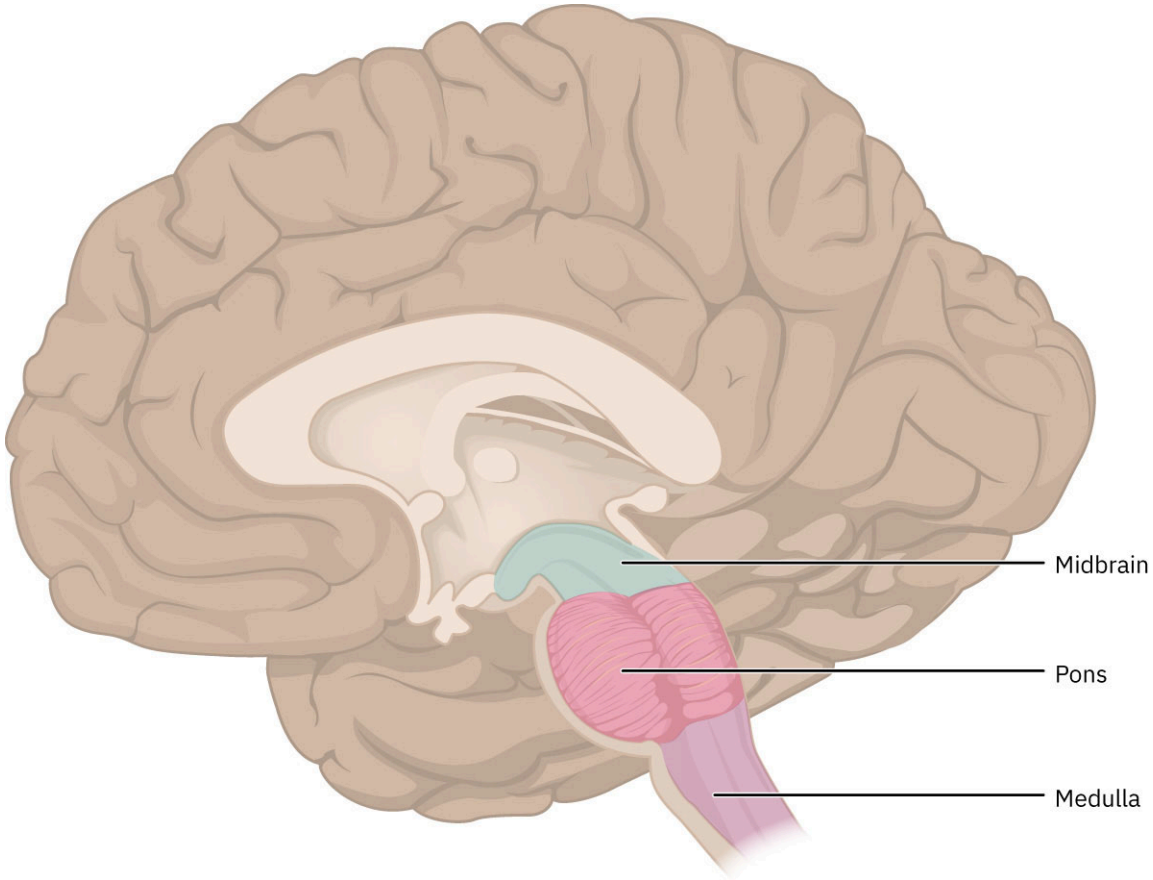

FIGURE 15.4 The brainstem comprises three regions: the midbrain, the pons, and the medulla. (credit: modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The Cerebellum

The final structure of the brain is the cerebellum, or "little brain," aptly named because it is small and resembles the cerebrum it sits behind. The cerebellum is largely responsible for integrating sensory feedback for the body to produce coordinated movements. It plays a role in proprioception, along with the parietal lobe, and helps control balance and fine motor movement.

The Cranial Nerves

The cranial nerves (Figure 15.5) are primarily responsible for the sensory and motor functions of the head and neck. (One of these nerves targets organs in the thoracic and abdominal cavities as part of the parasympathetic nervous system.) There are twelve cranial nerves, which can be classified as sensory nerves, motor nerves, or a combination of both (Table 15.1). The nurse can recognize deficits in specific cranial nerve function when brain vasculature has affected tissue where the nerve originates.

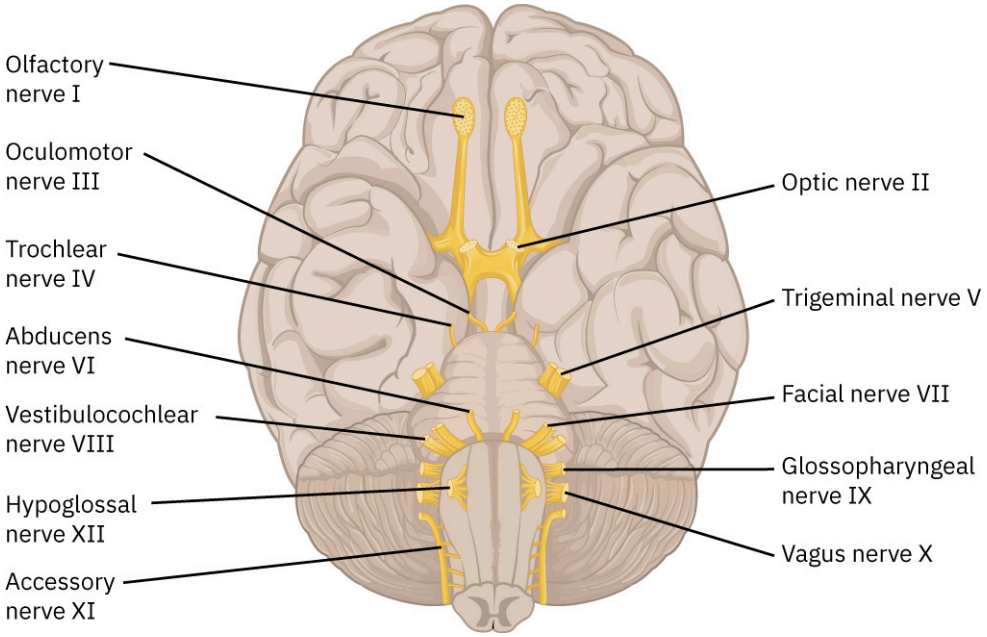

FIGURE 15.5 The cranial nerves originate from the base of the brain. (credit: modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Number	Name	Responsible for . . .
I	Olfactory nerve	• Sense of smell
II	Optic nerve	• Vision
III	Oculomotor nerve	• Eye movements (by controlling four of the extraocular muscles) • Lifting the upper eyelid when the eyes point up • Pupillary constriction
IV	Trochlear nerve	• Eye movement and ability to track
V	Trigeminal nerve	• Sensations of the face • Controlling the muscles of mastication
VI	Abducens nerve	• Eye movement (different extraocular muscle from the trochlear nerve)
VII	Facial nerve	• Muscles involved in facial expressions • Anterior part of the tongue • Production of saliva
VIII	Vestibulocochlear nerve	• Senses of hearing and balance

TABLE 15.1 Cranial Nerves

Number	Name	Responsible for . . .
IX	Glossopharyngeal nerve	• Controlling muscles in the oral cavity and upper throat • Posterior part of the tongue • Production of saliva
X	Vagus nerve	• Contributing to homeostatic control of the organs of the thoracic and upper-abdominal cavities
XI	Spinal accessory nerve	• Controlling the muscles of the neck to allow for shrugging of the shoulders and rotation and tilting of the head
XII	Hypoglossal nerve	• Controlling the muscles of the lower throat and tongue

TABLE 15.1 Cranial Nerves

Protecting the Brain

From superior to inferior, the layers of the dura mater, arachnoid mater, and pia mater comprise the meninges, which are membrane layers of connective tissue. The skull and meninges are designed to protect the vital and dynamic brain. The skull is a rigid, skeletal structure encasing the brain in a finite space (Figure 15.6).

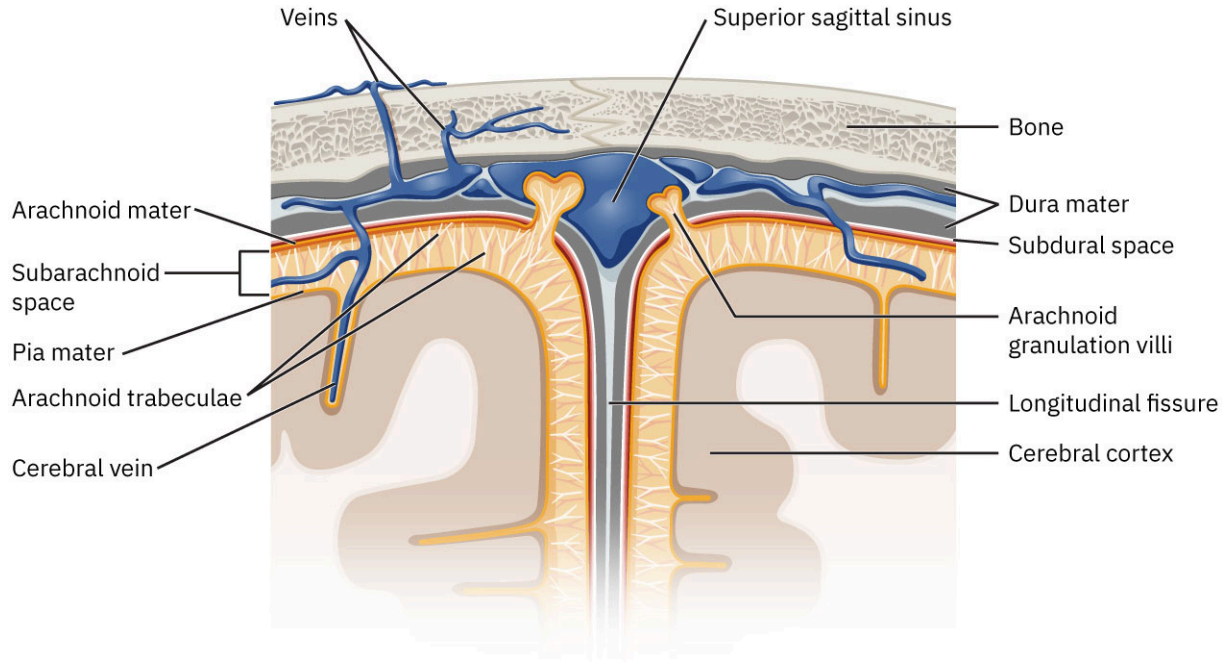

FIGURE 15.6 The three connective tissue layers of the meninges protect the brain: the dura mater, arachnoid mater, and pia mater. The subdural and subarachnoid spaces are the small areas below the respective layers. This image also includes the skull bone, directly above the dura mater. (credit: modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

- The dura mater is a thick, fibrous layer that acts as a strong protective sheath over the entire brain. The name comes from the Latin for "tough mother," to represent its physically protective role.
- The middle layer is the arachnoid mater, which is a membrane of thin, fibrous tissue that forms a loose sac around the brain. The name also comes from Latin; it means "spiderweb-like mother" because the layer looks like a spiderweb. It is filled with circulating cerebrospinal fluid (CSF), which provides a liquid cushion to the brain.
- Finally, directly adjacent to the surface of the brain is the pia mater, which is Latin for "tender mother." This innermost layer is a thin fibrous membrane that fits into the grooves and indentations of the brain's surface. It

is thought to have a continuous layer of cells providing a fluid-impermeable membrane.

Of note, the meninges surround the entire CNS, which includes the brain and spinal cord.

The Circle of Willis

The cerebral vasculature system is complex for good reason. The anatomical structure contains the **circle of Willis (CoW)**, which is a place where cerebral arteries meet and divide in a way aimed to maintain perfusion of the brain: If narrowing or a blockage limits flow through one part, blood can still flow through other parts (Figure 15.7). Knowing the basics of cerebral blood flow will help the nurse understand which areas may be impacted by an occlusion in a specific vessel of the brain and assist in understanding how collateral perfusion may help certain occlusions from causing a more devastating injury. The external carotid arteries supply blood to the tissues on the surface of the cranium. The internal carotid arteries are responsible for the blood flow to most of the cerebrum (frontal, parietal, lateral, and temporal lobes, as well as the anterior part of the deep cerebral hemisphere). This is considered the anterior circulation. The posterior circulation, supplying the brainstem, cerebellum, occipital lobes, and part of the deep hemisphere (thalamus), is fed by the vertebral arteries. The vertebral arteries meet to make the basilar artery.

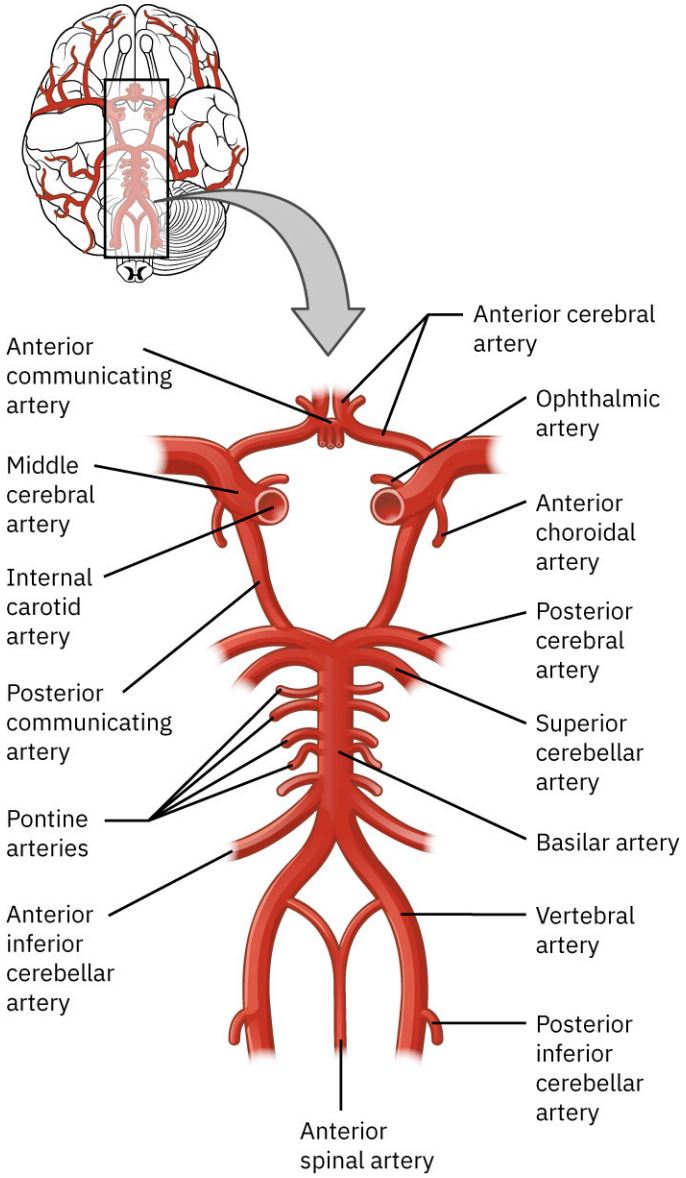

FIGURE 15.7 The blood supply to the brain enters through the internal carotid arteries. (credit: modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The left and right internal carotid arteries and branches of the basilar artery all become the CoW. The anterior

portion of the CoW is joined by the anterior communicating artery and continues to form the middle cerebral arteries, which connect to the posterior communicating artery. This connects with the basilar artery. The basilar artery splits to the bilateral vertebral arteries, also responsible for supplying the posterior part of the brain (Rosner et al., 2023). Essentially, blood supply enters the brain through one of the main vessel routes, anteriorly (carotids) or posteriorly (vertebral arteries), but circulation is connected from there by the CoW to provide means for collateral blood flow should one vessel become damaged.

Recognizing and Responding to a Cerebrovascular Accident

Any time there is an obstruction of the arteries responsible for blood flow to the brain, perfusion becomes limited, thereby causing brain cells to be deprived of vital oxygenation. Ischemia, deprivation of oxygen, and infarction as the result of decreased perfusion cause diminished function but not always cellular death. This is considered a **cerebrovascular accident (CVA)**, or stroke. It is important to be familiar with the anatomy and function of the brain, as well as the organization of the vessels supplying the brain with blood, to be able to understand how strokes can damage certain areas, resulting in varying deficits. The nurse who is knowledgeable about the brain and cerebral blood flow will be better able to recognize symptoms and care for patients who experience a CVA.

A cerebrovascular accident is a medical emergency requiring immediate hospital care. If signs and symptoms are recognized in a hospitalized patient, the appropriate steps to obtain immediate assistance should be taken right away.

CLINICAL SAFETY AND PROCEDURES (QSEN)

QSEN Competency: Evidence-Based Practice (EBP)

Disclaimer: Always follow the facility policy for medication administration.

Definition: Use best practice standards and current evidence-based research with clinical judgment and patient/family preferences to provide optimal quality health care.

Knowledge: The nurse will describe primary, evidence-based sources for locating best practice standards and current clinical practice guidelines.

Skill: The nurse will use clinical judgment and critical thinking to implement individual plans of care.

Attitude: The nurse will place emphasis on evidence-based guidelines when determining current practice techniques. The nurse will value the need for continuous, lifelong learning.

Goal: Stroke Phase III guidelines outline the treatment of ischemic stroke with medication, as door-to-needle time. Evidence suggests the best practice is for treatment to begin within 60 minutes for 85 percent or more patients. For surgical clot removal, evidence suggests the procedure should take place within 90 minutes in 50 percent of patients. Research concludes achieving the identified time improves the quality of care and decreases the risk of long-term disability from a stroke

(American Heart Association, 2019)

At some institutions, a rapid response team may be activated. Some facilities have a specific stroke response team. Knowing the policy and protocol for your hospital is imperative. When signs and symptoms of a stroke are recognized outside of the hospital, emergency response should be activated. This most often involves calling 911 for a quick response, initiation of treatment, and transfer to the appropriate hospital for providing the needed care. Hospitals can receive different levels of certification by the Joint Commission for excellence in stroke care.

LINK TO LEARNING

This fact sheet outlines the four different levels of stroke certification (https://openstax.org/r/77StrokeCertLev) that accredited hospitals can earn from the Joint Commission. A certification guarantees standardized, best practice for care, ensuring patients will have the best outcomes possible.

Signs and Symptoms of CVA

The signs and symptoms of a CVA can vary greatly. This variance exists because an occlusion can occur anywhere within the cerebral vasculature and cause an **infarct**, or area of necrotic tissue, in any part of the brain that the occluded vessel should supply. The most commonly occluded artery is the middle cerebral artery (MCA), which is responsible for blood supply to parts of the cerebrum, including the temporal, frontal, and parietal lobes. Depending on the involvement of one to up to four of the MCA branches, signs and symptoms of an occlusion could include:

- **hemiplegia**, or complete paralysis on the side of the body opposite the CVA
- **hemiparesis**, or weakness on the side of the body opposite the CVA
- sensory changes of the face and arm on the side of the body opposite the CVA
- **aphasia**, or loss of language skills affecting expression, comprehension, or both, depending on the severity of the CVA
- **homonymous hemianopsia**, or a deficit causing a loss of vision in the same halves of the visual field in each eye

The anterior cerebral circulation includes the vessels that originate from the carotid arteries, and occlusions result in lateralizing neurological signs and symptoms. Occlusions in the internal carotid artery (ICA) can result in:

- paralysis of and sensory changes in the face, leg, and arm on the side of the body opposite to the CVA
- aphasia
- **apraxia**, or the inability to perform tasks, movements, or gestures
- homonymous hemianopsia

Anterior cerebral artery (ACA) occlusions can result in:

- paralysis and sensory changes of the foot or leg on the side of the body opposite the CVA
- gait impairments
- cognitive impairment
- urinary incontinence
- flat affect
- increased distractibility
- lack of interest in surroundings

In contrast, the posterior cerebral circulation includes the vessels that originate from the vertebrobasilar arteries and results in diffuse neurological signs and symptoms. Occlusions in the vertebral artery (VA), which supplies the cerebellum and brainstem, can cause dizziness, **nystagmus** (rapid, uncontrolled eye movements), **dysphagia** (trouble swallowing), **dysarthria** (trouble speaking), gait abnormalities, and facial weakness and numbness on the same side of the body as the stroke. Another vessel responsible for posterior supply is the basilar artery (BA). Occlusions there can result in quadriplegia, weakness of the mouth and throat, or even **locked-in syndrome**, a rare condition in which patients retain consciousness but develop paralysis of the entire body except in the muscles of eye movement. A CVA of the posterior inferior cerebellar artery (PICA) causes nausea, vomiting, dysphagia, dysarthria, nystagmus, ataxia, vertigo, and loss of sensation of pain and temperature on the side of the body opposite the stroke. Finally, occlusions in the posterior cerebral artery (PCA) can result in visual and memory deficits, **perseveration** (continuous and repetitive speech, behavior, or thoughts), abnormalities in pupils, and sensory loss. Table 15.2 summarizes these deficits for the major stroke locations.

Stroke Location	Common Deficits
MCA	• hemiplegia • hemiparesis • aphasia • homonymous hemianopsia
ICA	• paralysis of and sensory changes in the face, leg, and arm on the side of the body opposite to the stroke • aphasia • apraxia • homonymous hemianopsia • one-sided neglect
ACA	• paralysis and sensory changes of the foot or leg on the side of the body opposite to the stroke • gait impairments • cognitive impairment • urinary incontinence • flat affect • increased distractibility • lack of interest in surroundings
VA	• dizziness • nystagmus • dysphagia • dysarthria • gait abnormalities • facial weakness and numbness on the same side of the body as the stroke
BA	• quadriplegia • weakness of the mouth and throat • locked-in syndrome
PICA	• nausea • vomiting • dysphagia • dysarthria • nystagmus • ataxia • vertigo • loss of sensation of pain and temperature on the side of the body opposite the stroke
PCA	• visual and memory deficits • perseveration • abnormalities in pupils • sensory loss

TABLE 15.2 Common Stroke Deficits by Vessel Occluded

The signs and symptoms of a hemorrhagic versus an ischemic stroke may not differ much. Whether blood flow is impaired by the presence of a clot (**ischemic stroke**) or a leak or rupture in the vasculature of brain (**hemorrhagic stroke**), function can still be impaired in the same way. An infarct of either kind in the occipital lobe still manifests with visual impairment. An infarct of either kind in the cerebellum may still cause balance and coordination problems. The main differences that may be appreciated involve extra findings in hemorrhagic stroke. Patients with hemorrhagic strokes will more often complain of neck pain, photosensitivity, or nausea and vomiting; patients often present with subjective complaints of the worst headache of their life. These patients are much more likely to have a decreased level of consciousness than patients with ischemic strokes. A hemorrhagic stroke is usually more devastating than an ischemic stroke (Salvadori et al., 2020).

FAST and BE-FAST

A common acronym for recognition of stroke signs and symptoms is FAST: face, arm, speech, time.

- Face: Look for facial drooping, especially on one side. Is the patient's smile uneven?
- Arm: Look for weakness or numbness of the arm. Can the patient lift both arms up and hold them there?
- Speech: Look for slurred speech or problems with communication. Can you understand what the patient is saying? Can they understand you?
- Time: Call 911 immediately when you notice these symptoms. Ask yourself: How can I get help now?

However, a newer acronym, BE-FAST, has been found to identify strokes that would be missed by the FAST algorithm (Chen et al., 2022). BE-FAST adds two letters, B and E, for balance and eyes.

1. Balance: Check if the patient has trouble remaining upright. Does the patient have trouble walking, standing, or sitting up straight?
2. Eyes: Look for any visual changes. Does the patient have trouble seeing out of one or both eyes? Do they have a new onset of double or blurry vision?

Emergency CVA Treatment

Recognizing the signs of a CVA and initiating quick treatment are essential for preserving as much brain tissue, and therefore function, as possible. The phrase "time is brain" is often repeated for emphasis on rapid care, highlighting this fact. Upon arrival to the emergency department (for patients in the community) or after a stroke notification has been sent to the appropriate responding team (for hospitalized patients), a head computed tomography (CT) scan is performed to determine whether the symptoms are being caused by an ischemic or hemorrhagic stroke. To certify a hospital as "Acute Stroke Ready," the Joint Commission expects to see CTs initiated in ≤ 25 minutes of patient arrival and a radiologist reading within 45 minutes (Joint Commission, 2023).

If a hemorrhagic stroke is ruled out by the absence of a bleed, a clot is the assumed cause of the infarction. A **tissue plasminogen activator (tPA)** can then be administered intravenously to dissolve the clot and restore perfusion. To be effective at reversing brain ischemia, tPA must be administered within 3 to 4.5 hours of stroke onset, or the time when the patient was last seen as normal ("last known well").

If bleeding is present, signifying a hemorrhagic stroke, immediate care must be taken to determine the source of the bleeding and control the bleed or pressure within the skull (Caplan, 2023). Just as with a clot in an ischemic stroke, the brain cells are not being properly perfused, which damages brain tissue and impairs function. If the time between stroke onset or "last known well" is past the 3–4.5 hour time frame for intervention, measures to restore perfusion may not be effective in saving the brain. The longer the time to treatment, the more brain cells die, causing irreparable neurological damage that may result in paralysis, permanent disability, or even death.

LINK TO LEARNING

The American Heart Association published a resource that outlines three measures, or sets, of guidelines: stroke achievement, stroke quality, and stroke reporting (https://openstax.org/r/77GetWithGuide) called "Get with the Guidelines." It recommends that hospitals meet these guidelines to provide the best stroke care informed by scientific evidence. Hospitals achieving measurement goals are recognized formally during the International Stroke Conference and given promotional materials to advertise their expertise in their communities.

Diagnostics

A CT of the head is the gold standard for determining whether a stroke is ischemic or hemorrhagic. After the initial head CT without contrast, diagnostic tests related to CVA care can vary in relation to the type of stroke. For instance, a second head CT with contrast dye can be done for an ischemic stroke. This imaging will reveal the location and size of the infarction as well as the **penumbra**, or area immediately around the infarction receiving marginal blood flow. The penumbra is the tissue at greatest risk for injury but still salvageable with the restoration of perfusion. Another possible diagnostic study is a cerebral angiogram, which may identify vascular abnormalities responsible for bleeds in patients with hemorrhagic stroke.

A diagnostic tool that is used regardless of the type of stroke is the National Institutes of Health Stroke Scale (NIHSS). Though other scoring methods exist, the NIHSS is the most widely used. The NIHSS should be performed immediately upon initiation of stroke care. Scores range from 0 to 42, with higher numbers indicating a more severe stroke. The NIHSS is performed by a physician or other trained individual (often a registered nurse) to determine the severity of the stroke. The person administering the scale asks the patient to perform some physical and mental tests to objectively score their alertness and ability to communicate and perform movements. NIHSS is also a prognostication tool; studies have found that higher scores are indicators of poorer outcomes.

LINK TO LEARNING

The National Institutes for Health NIH Stroke Scale (https://openstax.org/r/77NIHStrokScale) quantifies stroke severity. Some important tips on using the scale correctly include scoring only what the patient does and not what you think the patient can do, not coaching the patient, and making sure to record the patient's first effort rather than their best effort.

Continued CVA Treatment

Subsequent emergency care focused on minimizing tissue infarction, support, and monitoring for multiple systems is essential. In the inpatient setting, a patient's blood pressure must be stabilized, nutrition must be optimized, and intracranial pressure changes, vital signs, blood glucose, neurologic status, and cardiac rhythm should be monitored. Causative factors are investigated, measures to prevent secondary stroke are initiated, and the rehabilitation process begins. The rehabilitation process could include an inpatient rehabilitation stay or even a transition to a long-term care facility when disability is severe. Care after a stroke involves not only the physical care and reconditioning of the body but also care to meet the patient's psychosocial and emotional demands. Continued stroke care requires the collaboration of individuals from many disciplines.

INTERDISCIPLINARY PLAN OF CARE

Interdisciplinary Plan of Care for a Patient Who Had a Stroke

An interdisciplinary plan of care includes a variety of health care professionals who work together to coordinate care for a patient who has had a stroke. Their goal is to provide continued care, management, and preventive measures after the initial acute hospitalization. The interdisciplinary team includes emergency response staff who initially respond to and apply interventions for stroke recognition and management. When a stroke occurs in a community setting, the team may include EMS, mobile stroke units, and emergency room staff. Inpatient stroke care may start with recognition by the primary nurse and activation of the hospital's stroke response team, as applicable. Larger hospitals provide stroke care on dedicated units or stroke inpatient care teams.

Other members of the interdisciplinary team may include:

- diagnostic imaging team members
- pharmacists
- nutritionists
- social workers
- therapists, including occupational, physical, recreational, and speech language

- mental, behavioral, or neuropsychological therapists
- primary care providers
- neurologists and specialists in stroke care
- various health educators
- rehabilitation nurses
- home care providers

15.2 Ischemic Stroke

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for ischemic stroke
- Describe assessment and diagnostics in ischemic stroke
- Apply nursing concepts and plan associated nursing care for the patient with an ischemic stroke
- Evaluate the efficacy of nursing care for the patient with an ischemic stroke
- Describe the medical therapies that apply to the care of the patient with an ischemic stroke

An ischemic stroke is when the obstruction of blood flow in the brain is caused by an occlusion in a vessel, most commonly by atherosclerotic fatty deposit build-up. About 87 percent of all strokes are ischemic (American Stroke Association, 2023). An ischemic stroke requires different initial care than a hemorrhagic stroke, mainly because the primary cause is a clot rather than a bleed from a vessel within the brain. Though the initial treatment differs, the roles of the nurse and the rest of the interdisciplinary care team can have many similarities in the later stages of treatment and care.

Pathophysiology

In thrombosis, an obstructive process prevents blood flow to regions of the brain. The most common risk factor is large vessel atherosclerosis. An ischemic stroke is most commonly caused by the fatty deposits, or plaques, found collecting on the lining of the vessel walls, seen in patients with atherosclerosis. These deposits can form a **cerebral thrombus**, which is essentially a clot within a blood vessel that blocks cerebral perfusion. Alternately, the clot preventing perfusion could be a **cerebrovascular embolus**, which forms elsewhere in the body (such as the heart or carotid arteries), breaks off, and travels to the blood vessels of the brain. The embolus then gets lodged in a smaller vessel in the brain and prevents perfusion, causing a **cerebral embolism**. Such embolisms most commonly form in the left atrium of the heart in patients with atrial fibrillation, a heart dysrhythmia discussed in Chapter 12 Cardiovascular System (American Stroke Association, 2023).

Ischemic strokes fall into four categories: large artery thrombosis, small artery thrombosis, cardiogenic embolism, and cryptogenic. A large artery thrombosis is a plaque occlusion of blood flow in a larger vessel. The larger vessels responsible for cerebral perfusion are the basilar artery, the middle cerebral artery (MCA), and the carotids in the neck. A small artery thrombosis, often referred to as a **lacunar stroke**, occurs in the small arteries in the brain that branch off from the larger vessels. These can be caused by high cholesterol, atherosclerosis, diabetes, or high blood pressure.

Cardiogenic strokes are those caused by clots traveling into the brain from the heart. Some common cardiac conditions that cause emboli to form are arrythmias such as atrial fibrillation, valvular heart disease such as endocarditis, prosthetic heart valves, recent myocardial infarction, and some ventricular diseases. Another common cause is the presence of a **patent foramen ovale**, a small hole between the left and right atria to support fetal circulation; the hole usually closes on its own, but it remains open after birth for 25 percent of the population (American Heart Association, 2023). A cardiogenic embolus may occur due to cholesterol accumulation, platelets or other blood clots, calcium, or accumulated bacteria. Such emboli can enter systemic circulation and travel throughout the body. However, more than 80 percent of such clots travel to the brain (Pillai et al., 2022).

The final type of ischemic stroke is a **cryptogenic stroke**. A cause cannot be determined for this type of stroke, regardless of testing done to identify the common causes. Studies have reported an increased incidence of cryptogenic stroke among African Americans and Hispanics (American Stroke Association, 2023).

Though it is not a type of stroke, **transient ischemic attack (TIA)** deserves mention. Often referred to as a “mini-

stroke," a TIA is caused by an occlusion of the blood vessels perfusing parts of the brain, just like a full stroke. The difference is that in a TIA, the clot dislodges or dissolves on its own, restoring perfusion before any permanent damage to the brain can occur. It can cause the same symptoms as a full stroke and symptoms can last from minutes up to twenty-four hours; however, there is no permanent loss of function. A "mini-stroke" is dangerous because it usually indicates that a full stroke will occur: The 90-day stroke risk after a TIA is almost 18 percent (Amin et al., 2023). It is important to determine the cause of a TIA so the condition can be treated, thereby decreasing the risk of a full stroke.

LIFE-STAGE CONTEXT

Older Adults and Risk for Stroke

Age-related changes are associated with increases in systolic blood pressure readings but do not have the same effects on the diastolic blood pressure readings. Isolated systolic hypertension is the most common type of hypertension in adults over the age of fifty. Isolated systolic hypertension is associated with increased risk of stroke. Older adults should begin treatment with lifestyle modifications.

(Tan & Thakur, 2023)

Clinical Manifestations

The clinical manifestations of an ischemic stroke can vary depending on which area of the brain is not being well perfused; another factor is the size of the clot impairing perfusion. In general, the symptoms of large vessel strokes present very suddenly. A patient with a large artery ischemic stroke may have weakness or paralysis on one side of the body, a loss of sensation to one side of the body, visual changes, problems with balance or coordination, issues with word-finding, or aphasia. A small vessel, or lacunar, stroke generally causes one-sided deficits: facial droop, weakness or paralysis in the arm or leg, impaired or complete loss of sensation, and ataxia. It may also manifest with dysarthria. The symptoms of a small vessel stroke often appear more gradually than a large vessel stroke, and deficits are often fewer because the small vessels perfuse a smaller area of the brain. Larger vessels are responsible for delivering blood to a larger region of the brain, so the symptoms can be greater.

A patient with an ischemic stroke may present with other symptoms, too, including vertigo or dizziness, neck stiffness, memory loss, confusion, or even nausea and vomiting. In fact, dizziness and vertigo are the most common symptoms in a missed stroke diagnosis. The presentation of a stroke can vary and be nonspecific. The most important thing to know is that brain cells die within minutes of not receiving adequate oxygen through cerebral perfusion, so early recognition and intervention are essential for reducing poor outcomes.

Assessment and Diagnostics

Stroke assessment is based on subjective data, but it is also important to conduct a complete neurological assessment, which is objectively rated using the National Institutes of Health Stroke Scale (NIHSS). The NIHSS also is a prognosticator: Lower scores generally predict a more devastating stroke. Subjectively, the most important question you can ask is, "When were you last seen acting normal?" This data is imperative since stroke onset is considered to be when the patient was "last known well," or without symptoms; treatments to save brain tissue and function are time-sensitive. Other subjective data include a health history, focusing on diseases (such as diabetes mellitus and hypertension) and lifestyle factors (such as nicotine use and use of certain oral contraceptives) that may increase stroke risk; providers should also ascertain whether the patient had previous strokes or TIAs. The objective neurological assessment involves five areas: cognition, cranial nerves, motor function, sensory function, and gait. A complete neurological exam will reveal deficits used to help localize the area of the brain affected, and then the NIHSS will be used to determine the severity and prognosis of the stroke.

Diagnostics and Laboratory Values

The diagnostic imaging for stroke begins with a STAT head CT without contrast dye. This CT is done to determine whether a bleed in the brain is present, signifying a hemorrhagic stroke rather than an ischemic stroke. The treatment of a hemorrhagic stroke is very different from the treatment of an ischemic stroke, so the results of the CT will allow the provider to decide on a treatment plan.

Diagnostic studies after the initial head CT are focused on determining the location, size, and impact of the infarct, or area of necrosis, formed by the interruption in perfusion. Diagnostic studies can also provide details to find the cause of the stroke. If a cause can be identified, measures can be taken to reduce the risk of a subsequent stroke.

To view the impact of the infarction on the brain, magnetic resonance imaging (MRI) is essential. An MRI with diffusion-weighted imaging (DWI) allows visualization of not only ischemia related to stroke but identifies the penumbra, the brain tissue that has been hypoperfused as a result of the occlusion but is not yet ischemic. The DW-MRI may be done right after the initial head CT to further determine the course of treatment.

Subsequent diagnostic imaging will be conducted to help reveal the cause of the stroke by first looking at the vasculature. This may include a computed tomography angiography (CTA), a magnetic resonance angiography (MRA), angiography, or ultrasonography. MRAs and CTAs are noninvasive scans that provide a view of the vessels within the brain and neck and allow vascular abnormalities, such as occlusions and stenoses, to be visualized. A CTA is a more sensitive test than an MRA, but it is less widely available and requires the patient to receive an intravenous iodinated contrast dye. A cerebral angiography requires a catheter be inserted into the patient, usually through the femoral artery, and considerable amounts of contrast dye, but it provides detailed images of blood flow. Finally, ultrasonography is much less invasive. These tests can be completed at bedside; they allow for visualization of the carotids but not the vessels within the brain.

A stroke "work-up" aimed at identifying the cause of the stroke includes an electrocardiogram or telemetry monitoring, as well as a transthoracic or transesophageal echocardiogram (TEE). To help identify abnormalities in the heart's rhythm (namely atrial fibrillation) or structure anomalies (primarily a patent foramen ovale), laboratory studies include but may not be limited to the following:

- complete blood count (CBC) and basic metabolic panel (BMP) to analyze platelets and electrolyte levels;
- prothrombin time (PT), international normalized ratio (INR), partial thromboplastin time (PTT), and clotting factor Xa to measure clotting times because a patient with prolonged clotting times may not be eligible for tPA due to bleeding risk;
- thyroid-stimulating hormone (TSH) levels because hyperthyroidism increases the risk of developing atrial fibrillation and thus increases stroke risk;
- blood glucose levels because hypoglycemia symptoms can mimic stroke symptoms; diabetes is a risk factor for stroke, so hemoglobin A1C levels will be tested to assess average three-month glucose control;
- lipid blood test or cholesterol panel to check for high cholesterol;
- erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) to look for inflammation; and
- D-dimer test, which can indicate an increased clotting risk.

The assessment, diagnostic tests, and laboratory tests that assist in the identification of an ischemic stroke also detail the extent of the stroke, identify the brain tissue that can potentially be saved, and help determine the cause of the stroke. The reason that the stroke work-up is so labor intensive is that identifying the cause of a stroke assists in the collaborative efforts of the interdisciplinary team to treat the stroke and employ preventive actions to minimize the risk for another stroke.

Nursing Care of the Patient with Ischemic Stroke

A nurse is caring for a hospitalized patient in a medical-surgical unit. The nurse performs their morning assessment of the patient and notices several findings that are not within normal limits. Let's read on to see how the nurse uses clinical judgment in this situation.

Recognizing and Analyzing Cues

On assessment, the nurse first recognizes the following cues: the patient's face is drooping on the left side, the patient's speech is slurred, and the patient does not appear to be moving their left arm as well as their right arm when the nurse is assessing range of motion.

The nurse analyzes the cues, recognizing facial droop is related to cranial nerve VII and that slurred speech is called dysarthria. The patient clearly understands what is being said, but is unable to respond by speaking clearly. Finally, by assessing the patient's strength in both arms, the nurse can rate the strength of the right arm 5/5 but the left arm only 4/5. The nurse recognizes these three cues as neurological changes consistent with stroke warning signs.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The nurse analyzes the cues to determine the source of neurological changes, hypothesizing different rationales for signs and symptoms. After determining that the patient is having an acute stroke, the nurse prioritizes interventions for immediate action. When generating solutions, the nurse knows patient safety is most important. The nurse calls for the emergency stroke response to be activated at the facility. Larger hospitals may alert the specific stroke or neurology providers who respond immediately to the emergency; the protocol at smaller hospitals may be to call the rapid response team and notify the attending who is covering the patient. To ensure safety, the nurse does the following:

- positions the patient's head, neck, and body in proper alignment to aid in perfusion and prevent airway compromise
- applies supplemental oxygen per facility protocol
- initiates NPO status to reduce the risk of aspiration
- obtains vital signs to check the patient for adequate oxygenation and perfusion
- prepare and educates the patient for what may come next, such as preparing for transport to diagnostic imaging areas, obtaining two large IVs, and getting an accurate weight for weight-based tPA administration.

CLINICAL SAFETY AND PROCEDURES (QSEN)

QSEN Competency: Safety

Disclaimer: Always follow the agency's policy for medication administration.

Definition: Minimizes risk of harm to patients and providers through both system effectiveness and individual performance. The nurse will . . .

Skill: Demonstrate effective strategies to reduce the risk of harm to self or others.

Attitude: Value the contributions of standardization/reliability to safety. Patients suspected of having a stroke should be made NPO right away because one of the major stroke impairments is dysphagia.

- The patient should remain NPO until a trained nurse or speech–language pathologist can perform a swallow screen using an evidence-based tool.
- Swallowing should be evaluated to identify dysphagia and prevent aspiration before any PO food, fluids, or medications are given.

Evaluation of Nursing Care for the Patient with Ischemic Stroke

Evaluation is a critical component of the nursing process. Through evaluation, the nurse can assess the effectiveness of their interventions and modify their actions to help reach the desired outcome or solution that they generated.

Evaluating Outcomes

In the previously described scenario, the nurse focused on patient outcomes related to maintaining safety and optimizing the patient's prognosis status by initiating prompt interventions. The nurse's actions of initiating an emergency stroke response, focusing on patient safety (e.g., NPO status, proper body alignment to facilitate the best possible oxygenation and cerebral perfusion), and preparing the patient for the next steps in the stroke work-up aided in the speedy diagnosis and treatment of an ischemic stroke. Recovery from a CVA, however, is not instantaneous; residual deficits may be identified months after the initiation of rehabilitation. Thus, "recovery" in the acute care phase of stroke treatment cannot be used as an indicator of long-term outcomes.

Medical Therapies and Related Care

Initial or emergency stroke treatment focuses on reversing brain ischemia and initiating successful reperfusion. The subsequent treatment of ischemic stroke focuses on two areas: preventing subsequent strokes and minimizing the effects of long-term disability.

Thrombolytics

Only one kind of drug is used to treat ischemic stroke by dissolving the clot to restore perfusion: tissue plasminogen activator (tPA). Medications in this class are alteplase and tenecteplase. Treatment must be administered within 3–4.5 hours of stroke onset or "last known well" to be effective at reversing brain ischemia. This medication is given intravenously after a hemorrhage has been ruled out by head CT (because a thrombolytic agent could make a hemorrhage worse). The American Heart Association has set a door-to-needle time (meaning the time between when the patient arrives to an emergency department to the time tPA is administered) of 60 minutes or less in at least 85 percent of patients (American Heart Association, 2019).

The major risk associated with tPA is bleeding, particularly intracranial hemorrhage. Because of this bleeding risk, there are conditions that would make the patient ineligible for tPA treatment. The excluding factors include:

- oral anticoagulation therapy (INR > 1.7, PT > 15 seconds, or a PTT > 40 seconds)
- platelet count < 100,000/mm^3
- previous ischemic stroke or head trauma in the past three months
- gastrointestinal bleeding within the last 21 days
- intracranial or spinal surgery within the past three months
- persistent high blood pressure (systolic ≥ 180 mmHg or diastolic ≥ 110 mmHg)
- confirmed active internal bleeding
- infective endocarditis, or abnormal cardiac rhythms
- aortic arch dissection
- pregnancy or recent C-section

Other important considerations prior to tPA administration are ruling out hypoglycemia as the cause for symptoms, ensuring two large-bore (such as eighteen gauge) intravenous lines are in place, and obtaining an accurate weight for the patient since the tPA dose is weight-based (Oliveira-Filho & Samuels, 2023). After receiving tPA, the patient is closely monitored for at least twenty-four hours in an ICU or stroke-dedicated unit. Care is comprised of cardiac monitoring, routine neurological assessment, and frequent vital signs checks. During that time, the patient's blood pressure must be controlled to ≤ 180/105. It is necessary to obtain another CT or MRI twenty-four hours after tPA to rule out intracranial bleeding prior to starting antiplatelet or anticoagulant therapies.

Thrombectomy

Another treatment for ischemic stroke is a mechanical **thrombectomy**. This procedure essentially involves a catheter inserted through a vessel (commonly in the groin) to physically remove the clot from the cerebral artery. A thrombectomy is used only for large artery occlusions and must be done within twenty-four hours of stroke onset or "last known well." Clots occluding small arteries are too difficult to reach. A thrombectomy can be done with or without concurrent tPA treatment.

LINK TO LEARNING

Review the current guidelines for clinical management of patients diagnosed with an ischemic stroke (https://openstax.org/r/77GuideIschStrk) from the American Heart Association/American Stroke Association.

Continued Ischemic Stroke Management

After the initial treatment with tPA or a thrombectomy, or when a patient presents outside of the respective care windows, treatment is aimed at preventing subsequent strokes and minimizing the effects of long-term disability.

Blood pressure management is very important after a stroke. High blood pressure is almost always noted in patients with ischemic strokes. Most times, after the removal of a clot with tPA or thrombectomy, the brain still relies on a higher systemic blood pressure for reperfusion of the ischemic penumbra. To sustain the perfusion, the patient is initially allowed to maintain a higher blood pressure, called **permissive hypertension**. The systolic goal is < 160–180 mmHg for patients who have received tPA, but it may be even higher (up to 220/120) for those who did not receive tPA. Control within these parameters may require intravenous administration of labetalol or nicardipine. Reduction in blood pressure begins twenty-four to forty-eight hours after stroke intervention, at which time antihypertensive medications will be resumed or started.

An aspirin regimen should be started for stroke patients. Aspirin's antiplatelet effects help improve circulation. It is typically given orally but can be administered rectally to patients with impaired swallowing or whose swallowing ability has not yet been evaluated. The initial or loading dose is 325 mg, followed by daily treatment of 81 mg. Dual antiplatelet therapy is often a treatment for patients. Dual therapy adds clopidogrel: a loading dose of 300–600 mg, followed by 75 mg daily. Antiplatelet therapy continues for twenty-one days for smaller strokes and ninety days for larger strokes.

Hyperlipidemia is a major cause of atherosclerosis and thus stroke. Laboratory results commonly show elevated cholesterol and low-density lipoprotein levels in ischemic stroke patients. Pharmacotherapy, such as statin therapy, reduces the risk of subsequent strokes and is most often administered in the form of atorvastatin (80 mg daily).

Managing blood glucose is another way to reduce risk of subsequent stroke. The risk for stroke increases for patients with diabetes mellitus, particularly females. Patients with diabetes are more likely to have carotid atherosclerosis, which can impair cerebral perfusion. Glycemic control can be achieved through any combination of insulin, oral drugs, diet, and exercise to reach a goal of A1C ≤ 7 percent (Oliveira-Filho & Mullen, 2023). Education should also be provided regarding modifiable and nonmodifiable risk factors (Table 15.3).

Type of Risk Factor	Factors
Modifiable	Alcohol consumption Atrial fibrillation Cardiac disease Diabetes mellitus Hyperlipidemia Hypertension Obesity Physical inactivity Sleep apnea Smoking Unhealthy diet
Nonmodifiable	Age (older adults at greater risk) Family history Prior stroke or TIA Race/ethnicity (Black and Hispanic/Latinx populations at greater risk) Sex (females have more strokes than males)

TABLE 15.3 Modifiable and Nonmodifiable Risk Factors for Ischemic Stroke

Complications during acute stroke may include risks for falls, aspiration, pressure injury, and venous thromboembolism. Complications specific to neurologic function are the risks for **hemorrhagic transformation** of the stroke, cerebral edema, and seizure. Hemorrhagic transformation is when a hemorrhagic infarct occurs after ischemic stroke; this risk increases after the administration of tPA. The health-care team needs to monitor closely for changes indicative of these complications, such as increased or new neurological deficits and changes in Glascow Coma Scale (GCS), and implement strategies to prevent them. A hemorrhagic transformation occurs when blood vessels in the brain rupture after reperfusion; this is usually within twenty-four hours for patients who received tPA or had a thrombectomy or within the first few days for untreated patients.

REAL RN STORIES

Nurse: John, RN
Years in Practice: Nineteen
Clinical Setting: Inpatient neurosciences unit
Geographic Location: Large, urban, mid-Atlantic hospital

I have been working as an RN on a busy, acute inpatient unit specializing in neurological and stroke care for nearly two decades. One day, when I first started in the unit, I was caring for a patient who had suffered an ischemic stroke two days prior and been treated with tPA. During my morning assessment, I found the patient to have a slight decrease in his strength of the upper and lower extremities on the right side, but no other apparent neurological deficits. The patient's vital signs were normal, and the telemetry monitor revealed a normal sinus rhythm. The patient had no slurred speech and stated nothing felt wrong.

As I quickly went to notify the charge nurse of my findings, the patient pressed his call bell and told the assistive personal that he had a bad headache. When I got to the room, I found the patient to be lethargic, with an increased respiratory rate. I immediately tried to arouse the patient. I checked the patient's pupillary response, which had been normal just minutes earlier, and found both pupils to be unreactive to light. I immediately called for help from the rapid response team, recognizing these signs of deterioration may point to a hemorrhagic transformation of the patient's previous ischemic stroke.

Other interdisciplinary team members who may be part of a patient's continued ischemic stroke treatment are physical, occupational, speech language, and recreational therapists. These professionals help with regaining muscle movement, strength, and control, as well as increased independence with ADLs and coping, confidence building, and improving socialization skills. They also help with learning to live with the disabilities that may result from stroke. Sometimes a patient may need to relearn or develop alternative strategies for daily activities and actions, such as safe movement and transfers, dressing, bathing, speech, swallowing, and higher-level thinking involved with activities like grocery shopping or playing card games. Therapists help make those adjustments. A neuropsychologist or other therapist may help with the effects on a patient's cognition and mental health. A nutritionist or dietician may teach the patient about foods that interact with new medications or help reduce cholesterol. A pharmacist may help the patient understand new medications. A social worker or case manager may be involved to help with placement in a rehabilitation facility or to orchestrate home nursing and therapy services after discharge. There are many people across a variety of specialties who are involved in continued stroke care and whose job it is to reduce long-term disability and the risk of future stroke in their patients.

Prevention

The primary stroke prevention recommendations by the American Heart Association/American Stroke Association are to stop cigarette smoking, increase physical activity, maintain a healthy weight, and control cholesterol, blood pressure, and diabetes. Risk factors that should be managed are atrial fibrillation, obstructive sleep apnea (OSA), migraine with aura, sickle cell disease, and hypercoagulable states (e.g., COVID-19, cancer). Finally, efforts to end alcohol or drug abuse should be initiated (Tai, 2022).

15.3 Hemorrhagic Stroke

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for hemorrhagic stroke
- Describe assessment and diagnostics in hemorrhagic stroke
- Apply nursing concepts and plan associated nursing care for the patient with a hemorrhagic stroke
- Evaluate the efficacy of nursing care for the patient with a hemorrhagic stroke
- Describe the medical therapies that apply to the care of a patient with a hemorrhagic stroke

A hemorrhagic stroke is less common than an ischemic stroke but often more devastating and debilitating; it is also much more likely to be fatal (Cleveland Clinic, 2022). A hemorrhage is a bleed, which can be from a rupture or leak in a cerebral vessel, either within the brain or around the brain. Bleeding in either location can take up room in the finite space of the skull, causing increased cerebral pressure and cerebral edema. This change in volume puts pressure on the brain and increases the intracranial pressure (ICP); increased pressure inside the cranium can result in neurological damage. Refer to Chapter 17 Nervous System and Chronic Diseases of the Nervous System for more details on ICP. Bleeds tend to expand quickly, so the patient's neurological status could change as well. Once again, the adage "time is brain" rings true: The faster a person can receive treatment, the lesser the damage and the better the outcome.

Pathophysiology

A hemorrhagic stroke is caused by the absence of proper perfusion to the cells of the brain, resulting from a rupture of either a vessel within the cerebral vasculature or around the brain. A hemorrhage, or bleed, in the cranium is called an intracranial hemorrhage. If the intracranial hemorrhage is within the cerebral vasculature, it is an **intracerebral hemorrhage (ICH)**. A bleed that occurs in the subarachnoid space directly surrounding the brain but still under the skull is called a **subarachnoid hemorrhage (SAH)** (Figure 15.8).

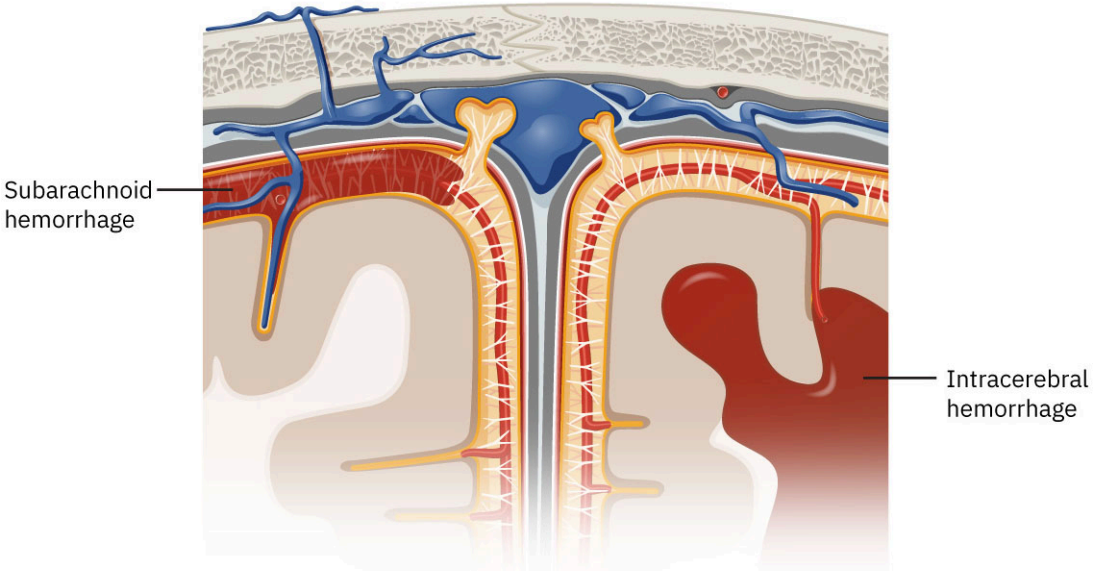

FIGURE 15.8 A hemorrhagic stroke is blood found between the various meninges or within the brain itself. The two different types of hemorrhagic stroke are an intracerebral hemorrhage (ICH), which is a bleed inside the brain, and a subarachnoid hemorrhage (SAH), which is a bleed in the area surrounding the brain. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Intracerebral hemorrhages are most often caused by hypertension. Over time, hypertension can degrade vessels, and the increased pressure within the vessel can cause the weakened vessel to burst. The small vessel disease arteriosclerosis also increases ICH risk by changing the vessel walls into stretched and weakened versions of themselves, increasing the risk of rupture. Finally, ICH may be caused by cerebral amyloid angiopathy (CAA), which is a disease that increases the fragility of the cerebral vessels, making them prone to bleeding. Arteriosclerosis and CAA are generally age related, whereas hypertension can develop at any age.

Patients taking anticoagulants or antiplatelets are at risk for ICH because their blood is "thinner," meaning that clotting times are increased. This makes a bleed from a vessel more likely to occur. Likewise, those who have chronic liver disease are also at greater risk for an ICH because of the associated coagulopathy and thrombocytopenia. Heavy alcohol use and cigarette smoking, as well as substance use (particularly of sympathomimetic drugs like cocaine, heroin, and methamphetamine), increase ICH risk. Cerebral trauma and bleeding from a brain tumor can cause ICH, as well as aneurysm ruptures and arteriovenous malformations. However, the latter two are more likely to cause SAHs (or subarachnoid hemorrhages).

SAH is most often caused by a just-ruptured aneurysm, a thinned or weakened spot in the vasculature that balloons and fills with blood. Another common cause is **arteriovenous malformation (AVM)**, an abnormal formation of blood vessels in which the arteries and veins can become tangled and form connections. AVMs can rupture and cause uncontrolled bleeding. SAH also occurs in cases of vasculitis and cerebral artery dissection. People at increased risk for SAH are those with hypertension or substance use disorders, as well as those who are pregnant or use estrogen-containing oral contraceptives.

Modifiable risk factors for hemorrhagic stroke are:

- hypertension
- smoking
- alcohol consumption

- antiplatelet or anticoagulant therapy
- sympathomimetic drug usage

Nonmodifiable risk factors for hemorrhagic stroke include:

- assigned male at birth
- advanced age
- Asian ethnicity
- chronic kidney disease
- cerebral amyloid angiopathy (CAA)

Clinical Manifestations

The clinical presentation of a hemorrhagic stroke may mimic that of an ischemic stroke because the same areas of the brain may be deprived of proper perfusion, resulting in the same deficits. The nurse is likely to observe aphasia, hemiplegia, dysphagia, and sensory changes. The deficits a patient displays depend on the location and size of the bleed. Because of the nature of a hemorrhage within the brain, a bleed is also likely to cause additional signs and symptoms that reflect the change in volume within the closed space of the skull. These include:

- decreased level of consciousness or coma
- **thunderclap headache**, a severe, sudden headache that peaks in intensity in seconds, lasts at least five minutes, and lingers and fades within a few hours
- vomiting
- seizure activity
- neck stiffness or pain
- photophobia
- increases in blood pressure

REAL RN STORIES

Nurse: Margaret, RN
Years in Practice: Two
Clinical Setting: Adult emergency room
Geographic Location: Urban

I have worked as an emergency room (ER) nurse for two years now. I commonly see patients coming in to be treated for unrelieved severe headaches. Most of time the headaches are diagnosed and treated as migraines. These often coincide with electrolyte imbalances or dehydration. Occasionally some of these patients' headaches include additional symptoms and are the result of meningitis or other infections.

One day, a 62-year-old male was brought in by ambulance. He complained of the worst headache of his life, which had started only a half an hour before and become so severe that his coworkers called 911 for emergency response. The EMTs reported vital signs of BP: 266/120, HR: 98, RR: 22, and SpO_2: 96 percent on room air. The patient was afebrile and had no other deficits.

I used clinical judgment to recognize cues of the headache's immediate onset and severity and to analyze the patient's vital signs. I then hypothesized that the patient could be experiencing a thunderclap headache. I knew thunderclap headaches are a symptom of hemorrhagic stroke. Taking action, I immediately notified the stroke response team and prepared to transport the patient for head CT upon arrival. Whether nurses are novice or experienced, critical thinking is imperative to providing quality patient care.

(Sekhon et al., 2023)

Blood accumulates most rapidly in the first four hours after initial leak or rupture, but expansion continues up to twenty-four hours. Though the initial injury in ICH is vessel damage, further damage can be caused by blood leakage and increased ICP, evolving cerebral edema, and ischemia that may linger for days or weeks (Hickey & Strayer, 2020). Complications can include inflammation, vascular compression, ventricular compression, brain herniation,

brainstem compression causing cardiorespiratory failure, and blood product toxicity.

Assessment and Diagnostics

It may not be possible to differentiate hemorrhagic stroke from ischemic stroke based on clinical manifestations alone. Hemorrhagic stroke presentation is acute and progresses rapidly. A thorough neurological assessment is critical, but diagnostic tests—including imaging and laboratory testing—are necessary to determine the type and cause of the stroke.

Obtaining and monitoring for changes in vital signs are important assessments. Hemorrhagic strokes often result from increased blood pressure and can continue to rise because of factors triggered by the bleed, such as elevated ICP, stress response, and damage to the central autonomic center. The evolving nature of the hemorrhage and cerebral edema can cause continued and rapid deterioration in neurological status. Neurological exams should be conducted regularly to monitor symptoms.

Decreases in level of consciousness associated with hemorrhagic stroke can be assessed using the **Glasgow Coma Scale (GCS)** (Table 15.4), which rates impairment of consciousness by scoring in three areas: eye opening, verbal response, and motor response. A completely unimpaired score is 15, and the lowest possible score is 3. Due to the evolving nature of the bleed and cerebral edema associated with hemorrhagic stroke, GCS may decrease as the stroke progresses—sometimes very rapidly. GCS must be reassessed at regular intervals.

Category	Score
Eye opening	4: Spontaneously 3: To speech 2: To pain 1: No response
Verbal response	5: Oriented to time, person, and place 4: Confused 3: Inappropriate words 2: Incomprehensible sounds 1: No response
Motor response	6: Obeys command 5: Localizes pain 4: Withdraws from pain 3: Abnormal flexion 2: Abnormal extension 1: No response

TABLE 15.4 Glasgow Coma Scale

Several additional scales exist for classifying ICH and SAH. They describe severity, prognosticate, or assess surgical risk. Table 15.5 lists three scales that are commonly used. Which scale is used depends on institutional protocol.

Scale Name	Purpose
Intracerebral hemorrhage (ICH) score (https://openstax.org/r/77ICHScore)	To standardize ICH rating for improved communication
Hunt and Hess classification (https://openstax.org/r/77HuntHess)	To assess SAH severity; to predict mortality
Fisher scale (https://openstax.org/r/77FisherScale) Modified Fisher scale (https://openstax.org/r/77ModFisher)	To index risk for vasospasm and delayed cerebral ischemia related to vasospasm after SAH

TABLE 15.5 Classification Scales for ICH and SAH

Diagnostics and Laboratory Values

Laboratory studies in hemorrhagic stroke mainly serve to find the reason for the bleed. Studies often include:

- complete blood count (CBC) and basic metabolic panel (BMP), blood glucose, and electrolyte levels to determine if underlying medical complications are present;
- prothrombin time (PT), international normalized ratio (INR), partial thromboplastin time (PTT), and clotting factor Xa to measure clotting times;
- liver and renal function tests to look for hepatic or renal cause;
- inflammatory markers produced in patients with CAA;
- urine toxicology screen to test for the presence of drugs in the system;
- pregnancy test for patients capable of becoming pregnant because pregnancy increases the risk of brain bleeds because of changes in circulating blood volume, hormonal changes, water retention, and hemostatic system changes.

Diagnostic imaging for hemorrhagic stroke always begins with a non-contrast head CT. A head CT is the first imaging done in response to the signs and symptoms of a stroke because it determines whether a bleed is present, dictating the course of treatment. When a bleed is present, an MRI can be used to investigate further. An MRI can be useful in measuring the volume of the hematoma; differentiating between primary hemorrhage and hemorrhagic transformation of pre-existing ischemic stroke; and identifying underlying causes of the bleed, such as AVMs, tumors, and vascular disease. Serial imaging monitors for changes in hematoma and edema, as well as the possible **mass effect** (compression of and injury to surrounding brain tissue because of the hematoma), **midline shift** (a displacement of brain tissue across the midline, shown in Figure 15.9), and the development of **hydrocephalus** (an increase in cerebrospinal fluid in the ventricles of the brain). Computerized tomography angiography (CTA) allows for visualization of hematoma expansion and the “spot sign” that shows active contrast extravasation and indicates active hematoma expansion. Ongoing bleeding evidenced in CTA is associated with higher fatality rates (Unnithan et al., 2023).

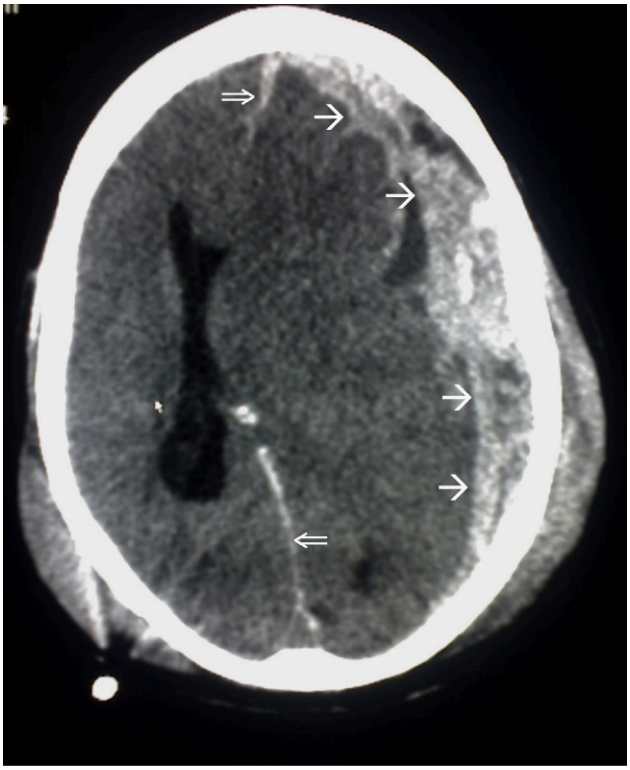

FIGURE 15.9 This CT image shows a midline shift (double arrows) due to a hematoma (single arrows). The brain tissue has been displaced so that the center, or midline, of the brain is no longer in the middle. (credit: Trauma subdural arrows by Glitzy queen00/Wikimedia Commons, Public Domain)

Finally, cerebral angiography may be performed to detect an aneurysm; this is the definitive diagnostic tool used. An AVM, or arteriovenous malformation, diagnosis can be made with cerebral angiography, too. In this procedure, the provider inserts a catheter into the patient's artery at the wrist or groin to explore the vessels of the neck and head. The aneurysms and malformations can be visualized, and the provider may intervene during the procedure. One intervention performed is a coil embolization for a ruptured aneurysm, described later in the chapter.

Nursing Care of the Patient with Hemorrhagic Stroke

A nurse on a neurological unit has an admission from the ICU: a patient who is three days post-hemorrhagic stroke. The next sections describe how the nurse uses clinical judgment in the case.

Recognizing and Analyzing Cues

The nurse performs an initial assessment on the patient and obtains vital signs. Vital signs are all within normal limits. The nurse notes the blood pressure is 128/88; looking at the trend in vital signs, the nurse notes that there has been a steady downward trend since admission, when the blood pressure was 210/102. The patient is sleeping and does not follow commands; however, the patient opens their eyes, groans, and mutters as the nurse stimulates the patient by squeezing their hand. The patient's pupils are equal and responsive to light. All other systems are within normal limits except for the skin. The nurse notes some redness on the patient's sacral area. In the nursing orders, the nurse notes the patient has not been ordered a diet but all the medications that were administered intravenously in the ICU are now ordered orally.

When analyzing the cues, the nurse notes the GCS to be 9 and does not notice any other neurological deficits. The nurse knows the importance of obtaining a baseline right away to note any changes, which can occur rapidly with a hemorrhagic stroke. The fact that the patient has redness on the sacral area alerts the nurse to the potential for skin breakdown. The nurse is also concerned that, even though the patient is not eating or drinking, they have been ordered oral medications that used to be given intravenously, an action that should not be taken until a formal swallow evaluation is given.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

When caring for a patient with a low GCS who cannot speak for themself, the nurse knows they will have to be

diligent about and advocate for the patient's safety. The nurse prioritizes monitoring for changes in neurological status, which would indicate an evolution in the hemorrhagic stroke. The actions the nurse will take include reassessing vital signs and neurological status every four hours as ordered.

As far as safety is concerned, the nurse will clarify the order for oral administration of medications with the provider. Because the nurse is regular staff on this neurological unit, they are aware of the AHA stroke measure that states patients should have a formal swallow evaluation before anything is taken by mouth. By holding all PO medications and contacting the provider for alternate routes of medication administration, the nurse may save the patient from aspiration.

The patient has limited consciousness and mobility and already exhibits redness in the sacral area. The nurse will be sure to reposition the patient every two hours, check if the patient had any episodes of incontinence at these regular intervals, and provide perineal and general skin care. The nurse will also prioritize their own safety by asking a colleague to help reposition the patient rather than try to move them alone, which could risk back injury. Also, because the patient has limited mobility, the nurse will ensure the patient is on appropriate venous thromboembolism (VTE) prophylaxis.

Evaluation of Nursing Care for the Patient with Hemorrhagic Stroke

When evaluating outcomes related to hemorrhagic stroke, the nurse focuses on recognizing changes pointing toward evolution of the stroke and maintaining stability. Evaluation allows the nurse to determine whether their interventions were effective or revised interventions are needed.

Evaluating Outcomes

In this case, the nurse continued performing vital sign and neurological checks every four hours to discover clues of worsening hemorrhage. Nothing was found, and the nurse will continue to monitor. As the nurse was unable to perform a swallow screen, based on the patient's mental status, the provider agreed that the patient should remain NPO. Medications were ordered to be administered IV and per rectum (PR). The fact that the sacral skin redness did not worsen but in fact improved a bit indicates that the nurse's skin integrity–related interventions are helping. Finally, the provider ordered sequential compression devices and subcutaneous heparin administration to prevent VTEs. The patient has no heat, swelling, warmth, or redness in the extremities.

Medical Therapies and Related Care

Medical treatment for hemorrhagic stroke depends on the cause of the bleeding. In general, once the cause of the bleed has been determined, therapies aimed at controlling the bleed, blood pressure, and ICP can be implemented more specifically. Treatments can be both surgical and nonsurgical.

One of the most important nonsurgical interventions is stopping medications that could increase bleeding; alternatively, the patient may be given medications to counteract the effects of the bleeding-increasing medications and promote clotting. For example, patients with an elevated prothrombin time may need to receive intravenous vitamin K to reduce progression of the bleed. Blood pressure management is another area of nonsurgical treatment focus. Hemorrhagic stroke is commonly caused by high blood pressure or pressure rises in response to the bleed. In either case, the American Stroke Association states that acute lowering of blood pressure is safe for patients with initial systolic blood pressures (SBP) ranging from 150 to 20; patients presenting with a SBP above 220 need aggressive reduction with continuous intravenous medications. Another nonsurgical treatment is monitoring for and treating seizure activity. Prophylactic antiepileptic drugs have no known benefits for treating strokes, but as many as 28 percent of patients have a seizure within the first twenty-four hours of a stroke and will require such medications (Greenberg et al., 2022).

Finally, the nonsurgical interventions associated with treating increased ICP are raising the head of the bed and administering osmotic diuretic drugs like mannitol. For continuous ICP monitoring, the best method is an invasive technique called a ventriculostomy (Figure 15.10). During a **ventriculostomy**, a hole is drilled through the skull and a catheter for measuring pressure is placed directly into the ventricle. The result is a display on a monitor that reads the intracranial pressure. This is often coupled with an external ventricular drain (EVD) that provides a way to drain cerebrospinal fluid (CSF) from the ventricles if the ICP becomes too high.

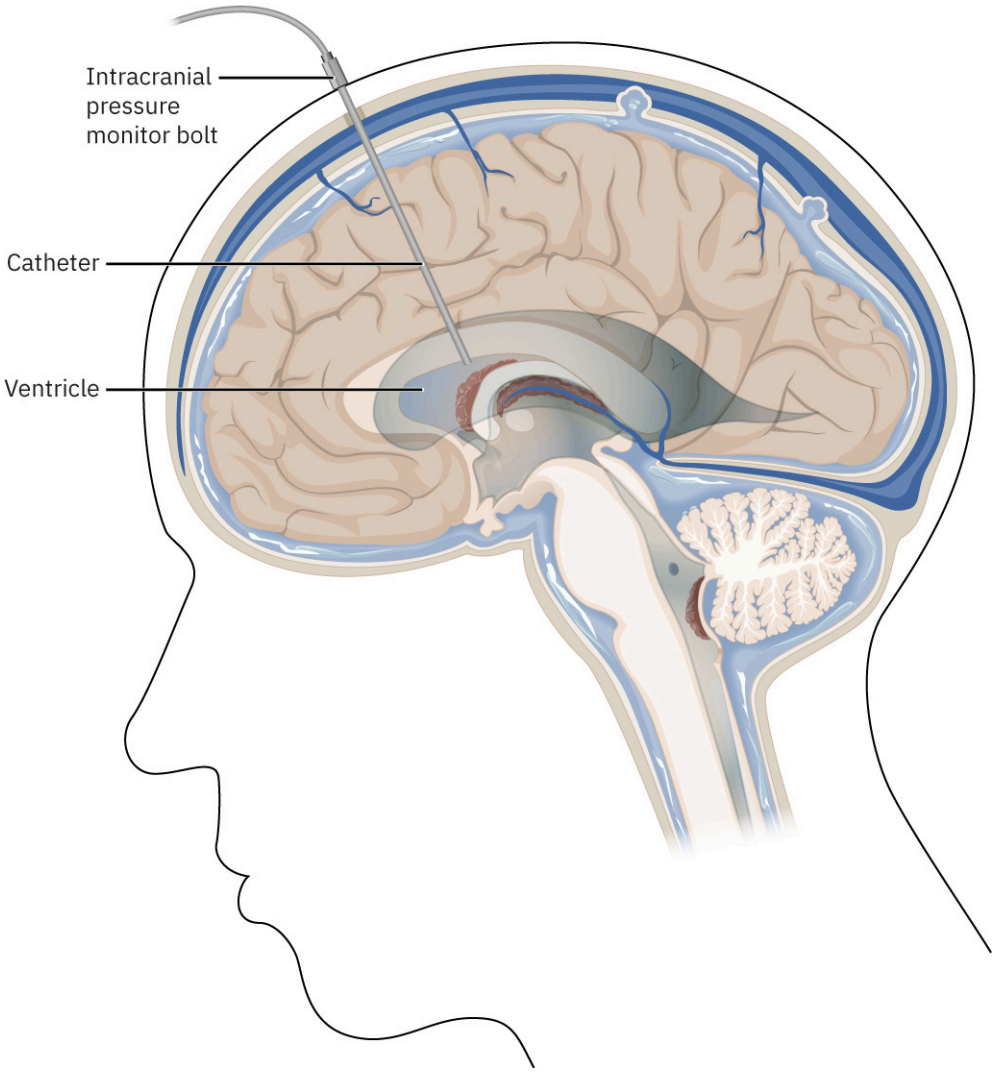

FIGURE 15.10 A ventriculostomy is an invasive technique for monitoring ICP. It can also include a drainage system (EVD) to drain CSF if needed. (credit: modification of work from *Anatomy and Physiology* 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Surgical interventions for hemorrhagic stroke aim to stop bleeding, aspirate the hematoma, or relieve pressure on the brain. Patients with an aneurysm often require a surgical procedure that exposes the brain aneurysm. The surgeon can then place a clamp or clip at the base of the aneurysm, which prevents it from bleeding or rebleeding. In a less-invasive, alternative procedure, a surgeon uses a catheter to place small coils in the aneurysm, which will eventually develop clots that prevent blood from flowing into the aneurysm.

A decompressive craniectomy is the removal of part of the skull to open the cranial vault and relieve pressure from cerebral edema. The skull piece is usually stored in the patient's abdomen or in a bone bank to be reinserted later. The care team must treat the patient with extra caution, such as using helmets to cover the unprotected brain when ambulating.

Hematoma evacuation via stereotactic aspiration is generally a minimally invasive surgery. Other options are endoscopic aspirations and catheter aspirations. A small opening is made in the skull and instruments are inserted to evacuate the hematoma. AVMs are treated with surgery, radiosurgery, or embolization.

The care for patients with hemorrhagic stroke is multi-faceted and ongoing. Health-care professionals across the interdisciplinary team need to be involved in the care to maintain safety, limit complications, and recognize symptoms of worsening neurologic status due to evolution or a rebleed.

Summary

15.1 The Cerebrovascular System and Cerebral Vascular Accidents

- The brain is a complex collection of vasculature and tissues. The brain itself comprises the cerebrum, the brainstem, and the cerebellum. The brain is protected by the skull and the meninges. The cranial nerves are responsible for the sensory and motor functions of the head and neck.
- Different areas of the brain are perfused by different branches of the circle of Willis (CoW). The functions of brain cells are dependent on perfusion needs.
- A CVA, or stroke, is an interruption of the blood flow to areas of the brain. Treatment of CVA is targeted at rapidly restoring perfusion needs, since the longer the brain is without proper blood flow, the greater the damage.
- A CVA can be ischemic (resulting from a vessel occlusion impairing blood flow) or hemorrhagic (resulting from bleeding within the brain impairing blood flow).

15.2 Ischemic Stroke

- An ischemic stroke results from a thrombus or embolus occluding blood flow in the brain. Ischemic strokes account for 87 percent of strokes.
- A head CT without contrast is the standard for first diagnosing a stroke. Subsequent imaging and laboratory blood testing will help practitioners determine the cause and treatment.
- The presentation and treatment of acute ischemic stroke differ from those of hemorrhagic strokes, but the care provided by the nurses and other intradisciplinary care team members is relatively similar.
- The medical treatments for acute ischemic stroke include administration of IV tPA and thrombectomy.
- The goals of care focus on saving the brain, minimizing the lasting effects or disability caused by the stroke, and preventing future strokes.

15.3 Hemorrhagic Stroke

- A hemorrhagic stroke results from bleeding into the brain caused by the rupture of a blood vessel. Hemorrhagic strokes are classified as intracerebral hemorrhages (ICH) or subarachnoid hemorrhages (SAH).
- A head CT is the standard for first diagnosing a stroke. Subsequent imaging and laboratory blood testing will help practitioners determine the cause and treatment.
- The presentation of and treatment for hemorrhagic strokes may differ from those of ischemic strokes, but the care provided by the nurses and other interdisciplinary care team members is relatively similar. All methods are focused on patient safety and providing the best possible outcome.
- The medical treatments for hemorrhagic stroke include hematoma evacuation and craniectomy.
- The goals of care focus on stopping the bleeding, determining the cause of the bleeding, controlling blood pressure, and monitoring and controlling intracranial pressure.

Key Terms

aphasia loss of language skills affecting expression (Broca's), comprehension (Wernicke's), or both (global), depending on the area of brain damage

apraxia inability to perform tasks, movements, or gestures

arteriovenous malformation (AVM) abnormal formation of blood vessels in which the arteries and veins can become tangled and form connections

central nervous system (CNS) body's processing and functional control center

cerebral embolism obstruction in which a clot forms elsewhere in the body, breaks off, and travels to the blood vessels of the brain

cerebral thrombus clot within a blood vessel that blocks cerebral perfusion

cerebrovascular accident (CVA) interruption in blood flow to cells within the brain; commonly referred to as a stroke

cerebrovascular embolus clot that forms elsewhere in the body, breaks off, and travels to the blood vessels of the brain

circle of Willis (CoW) location in the brain where cerebral arteries meet and divide in a way aimed to maintain perfusion

cryptogenic stroke stroke for which the cause cannot be determined
dysarthria trouble speaking
dysphagia trouble swallowing
Glasgow Coma Scale (GCS) objective measurement scale that rates impairment of consciousness by scoring in three areas: eye opening, verbal response, and movement
hemiparesis weakness on one side of the body
hemiplegia complete paralysis on one side of the body
hemorrhagic stroke bleeding into the brain caused by the rupture of a blood vessel
hemorrhagic transformation occurrence of a hemorrhagic infarct after an ischemic stroke, particularly after the administration of tPA
homonymous hemianopsia deficit causing a loss of vision in the same halves of the visual field in each eye
hydrocephalus increase in cerebrospinal fluid in the ventricles of the brain
infarct area of necrotic tissue in the brain
intracerebral hemorrhage (ICH) hemorrhage, or bleed, within the cerebral vasculature and brain tissue
intracranial hemorrhage hemorrhage, or bleed, in the cranium
ischemic stroke type of stroke in which a clot prevents blood flow to part of the brain
lacunar stroke small artery thrombosis
locked-in syndrome rare condition in which patients retain consciousness but develop paralysis of the entire body except in the muscles of eye movement
mass effect compression of and injury to surrounding brain tissue because of hematoma
midline shift displacement of brain tissue across the midline
nystagmus rapid, uncontrolled eye movements
patent foramen ovale small hole between the left and right atria to support fetal circulation that closes on its own in most cases
penumbra tissue that is immediately around an infarction, is receiving marginal blood flow, and is still salvageable with restoration of perfusion
permissive hypertension post-stroke condition in which the patient is allowed to maintain a higher blood pressure to support perfusion
perseveration continuous and repetitive speech, behavior, or thoughts
proprioception awareness of one's own body position and movement in relation to the space around oneself
subarachnoid hemorrhage (SAH) hemorrhage, or bleed, that occurs in the subarachnoid space surrounding the brain
thrombectomy procedure in which a catheter is inserted through a vessel to physically remove a clot from the cerebral vasculature
thunderclap headache severe, sudden headache that peaks in intensity in seconds, lasts at least five minutes, and lingers and fades within a few hours
tissue plasminogen activator (tPA) medication administered intravenously to break up a blood clot responsible for stopping cerebral blood flow
transient ischemic attack (TIA) temporary occlusion of the blood vessels perfusing parts of the brain, after which the clot dislodges or dissolves on its own, restoring perfusion; sometimes called a "mini-stroke"
ventriculostomy procedure in which a hole is drilled through the skull and a catheter for measuring pressure is placed directly into the ventricle

Assessments

Review Questions

1. In the FAST or BE-FAST algorithm for detecting stroke, what does the A stand for?
   a. arm
   b. aphasia
   c. alertness
   d. ataxia

2. The circle of Willis receives blood supply from which vessels? Select all that apply.

a. internal carotid arteries
b. internal jugular arteries
c. vertebral arteries
d. meninges

3. You receive a report from the emergency department that you are getting an admission who had a middle cerebral artery (MCA) stroke. You think about the common deficits seen with this type of stroke. What interventions might you prepare to implement? Select all that apply.
a. Make sure an antiemetic is prescribed r/t nausea and vomiting.
b. Ensure a bed/chair alarm is present to promote safety r/t hemiplegia.
c. Decrease risk for aspiration by providing thickened fluids r/t dysphagia.
d. Prepare for the patient to be intubated r/t respiratory distress.
e. Get a paper and pen ready for communication r/t aphasia.

4. A family member of a patient who had a stroke reports that the patient suddenly began to act impulsively, could not reason through simple problems, and experienced personality changes. What area of the brain does the nurse assume has been affected based upon the patient's presentation?
a. cerebellum
b. pons
c. frontal lobe
d. parietal lobe

5. What drug classification is used to treat ischemic stroke by dissolving the clot to restore perfusion?
a. thrombolytic
b. antiplatelet aggregators
c. anticoagulant
d. lipid lowering

6. What test(s) can be used for initial stroke diagnosis? Select all that apply.
a. CT/CTA
b. MRI/MRA
c. X-ray
d. ultrasound
e. carotid artery angiogram

7. What is a risk factor for ischemic stroke?
a. atrial fibrillation
b. recent respiratory infection
c. illicit drug use
d. assigned male at birth

8. What nursing intervention ordered by the provider would best help prepare a patient for administration of tPA?
a. providing a 1L fluid bolus
b. administering anticoagulants
c. inserting two large-bore IVs
d. maintaining the patient's NPO status

9. What statements would the nurse identify as measures of evaluation to decrease the risk of complications in the immediate care of the patient suspected of having an ischemic stroke? Select all that apply.
a. Patient remained NPO until swallow could be evaluated.
b. Patient maintained proper body alignment to facilitate cerebral perfusion.
c. Stroke symptoms resolved.

d. Patient was educated on ischemic stroke risk factors.

10. What patients are at increased risk for hemorrhagic stroke? Select all that apply.
a. an 88-year-old male
b. a 30-year-old pregnant person
c. a 35-year-old with testicular cancer
d. a 62-year-old experiencing homelessness
e. a 45-year-old who uses methamphetamines daily

11. What does a CT angiography show that a regular head CT would not?
a. location of the hemorrhage
b. volume of the hemorrhage
c. vascular malformations
d. active hematoma expansion

12. What nursing interventions should the nurse plan to implement for a patient with a hemorrhagic stroke? Select all that apply
a. perform neurological assessments regularly to identify changes
b. administer all medications through an NGT to reduce aspiration risk
c. maintain bedrest to reduce fall risk
d. assess vital signs daily to monitor for hypotension

13. A nurse is assessing a patient who recently had a hemorrhagic stroke. What finding would be the most positive outcome for maintaining patient safety?
a. The patient's blood pressure has remained stable.
b. The patient's GCS score has increased.
c. The patient can verbalize four stroke risk factors.
d. The patient has not experienced a fall.

14. A patient who had what surgery after a hemorrhagic stroke will likely require a helmet to protect the brain?
a. ventriculostomy
b. aneurysm coiling
c. decompressive craniectomy
d. hematoma evacuation via stereotactic aspiration

Check Your Understanding Questions

1. Describe the purpose of the circle of Willis.

2. Describe the functions of the different areas of the brain: the four lobes of the cerebrum, the brainstem, and the cerebellum.

3. Why is it important to perform a head CT prior to the initiation of tissue plasminogen activator (tPA)?

4. Describe a thunderclap headache.

5. How might a craniectomy help a patient who had a hemorrhagic stroke?

Reflection Questions

1. Why do the acronyms for stroke recognition, FAST and BE-FAST, include T for "time?"

2. What is one sign or symptom that might manifest in a stroke affecting the function of each of the twelve cranial nerves?

3. Though it is not possible to diagnose a hemorrhagic stroke versus an ischemic stroke solely on assessment findings, discuss some of the clinical manifestations that are likely to make the nurse suspect a hemorrhagic stroke rather than an ischemic stroke.

Competency-Based Assessments

1. Complete an internet search to locate the National Institutes of Health Stroke Scale. Using the scoring tool, assess a patient at your next clinical rotation who recently suffered a stroke and compare your findings with the documented score in the patients' medical record.
2. Develop an education pamphlet to hand out for a community health fair. The pamphlet should highlight interventions for the FAST protocol.

CHAPTER 16

Hematopoietic Disorders and Regulation

FIGURE 16.1 Blood collection is a skill needed to provide competent nursing care. Blood samples are used for critical diagnosis of a patient's condition. Components of a blood sample include plasma, erythrocytes, leukocytes, and platelets. (credit: Jessica Condit/Little Rock Air Force Base, Public Domain)

CHAPTER OUTLINE

INTRODUCTION The root *hemato-* comes from Greek and Latin words for blood. So, hematological disorders are diseases involving blood: specifically, the various structures and systems that produce blood, constitute it, and move it through the body. Blood makes up approximately 8 percent of the body by weight and consists of four main components (Mayo Clinic Staff, 2022):

- Red blood cells (RBCs; erythrocytes) transport oxygen.
- White blood cells (WBCs; leukocytes) fight infections.
- Platelets form clots to stop bleeding.
- Plasma carries red and white blood cells, platelets, and everything else—including a wide variety of nutrients, hormones, and waste products—through the circulatory system.

Understanding hematology is important for nursing professionals because blood components affect every body system and play crucial roles in maintaining the body's overall health. Each of the molecules found in a blood

sample—including water; oxygen; proteins, such as albumin, globulin, fibrinogen, and prothrombin; vitamins; sugars; fats; hormones; and waste products—can disrupt the body's homeostasis when their levels are either elevated or deficient. This chapter investigates the pathophysiology of the main disorders caused by blood imbalances, as well as appropriate treatments and approaches to nursing care.

16.1 Anemias

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations associated with the common types of anemia
- Describe the diagnostics and laboratory values for anemias
- Apply nursing concepts and plan associated nursing care for the patient with anemia
- Evaluate the efficacy of nursing care for the patient with anemia
- Describe the medical therapies that apply to the care of the patient with anemia

The **hematopoietic system** consists of the body structures responsible for the formation of blood cells. One of the most common hematopoietic disorders, **anemia**, is defined as deficient production of red blood cells (RBCs) or of **hemoglobin (Hb)**, a protein in RBCs that is key to the transport of oxygen from the lungs to cells and tissues. Table 16.1 identifies Hb levels in grams per deciliter (g/dL) of blood for different groups of people with and without anemia (WHO, 2024).

Group	Hb Level (g/dL)			
	No Anemia	Mild Anemia	Moderate Anemia	Severe Anemia
Children (>5 years)	≥11.0	10.0–10.9	7.0–9.9	<7.0
Children (5–11 years)	≥11.5	11.0–11.4	8.0–10.9	<8.0
Children (12–14 years)	≥12.0	11.0–11.9	8.0–10.9	<8.0
Nonpregnant females	≥12.0	11.0–11.9	8.0–10.9	<8.0
Pregnancy: First trimester Second trimester Third trimester	 ≥11.0 ≥11.0 ≥11.0	 10.0–10.9 9.5–10.4 10.0–10.9	 7.0–9.9 7.0 – 9.4 7.0–9.9	 <7.0 <7.0 <7.0
Males	≥13.0	11.0–12.9	8.0–10.9	<8.0

TABLE 16.1 Hemoglobin Levels and Anemia (WHO, 2024)

There are several types of anemia, each with distinct causes and clinical presentations, which can make management challenging. Some types, like iron-deficiency anemia, result from insufficient intake of essential nutrients, like iron, in food. In contrast, other anemias, such as sickle cell anemia, are hereditary conditions brought on by genetic mutations. Chronic illnesses, such as chronic kidney disease and inflammatory conditions, often contribute to secondary anemia as a side effect. However, all types of anemia deprive tissues and organs of the oxygen necessary to function optimally. Those affected by the disorder often experience debilitating symptoms including fatigue, weakness, pale skin tone, and shortness of breath. This diversity of causes and effects underscores the importance of being knowledgeable about anemia to ensure accurate diagnosis, appropriate treatments, and successful management for those living with it (Mayo Clinic Staff, 2022).

LIFE-STAGE CONTEXT

Anemia in Older People

Older adults are prone to anemia due to declines in their bone marrow production and immunity, as well as increased occurrence of myeloproliferative disorders (Mayo Clinic Staff, 2022). Changes in diet and access to nutrition may also play contributing roles in the prevalence of anemia. Older adults often associate fatigue and cold intolerance as symptoms of aging; however, often it is due to anemia. Nurses must encourage the older patient to get screened for and, if necessary, care for anemia. Supportive interventions centered around the patient's condition can alleviate symptoms if anemia has been identified as the source (Mayo Clinic Staff, 2022).

Pathophysiology of Anemia

Anemia can have several causes, but its general pathophysiology involves several key mechanisms affecting the production of RBCs. RBCs are produced within bone marrow. If bone marrow is damaged, such as from osteoporosis or bone cancer, it may no longer produce enough RBCs to meet the body's needs (WHO, 2024). Kidney damage can also hinder RBC production. In a healthy system, hypoxemia triggers the kidneys to release the hormone **erythropoietin (EPO)**, which, in turn, stimulates the bone marrow to produce RBCs. If the kidneys are damaged, such as in acute or chronic renal failure, the secretion of EPO may decrease or fully stop (WHO, 2024).

Another cause of anemia is blood loss or hemorrhage that exceeds normal RBC production, creating a net negative volume. Anemia can result from acute bleeding, as in trauma or surgery, or from chronic, low-level bleeding, as in gastrointestinal bleeding or heavy menstrual periods. When RBC loss exceeds RBC replacement, the blood loses oxygen-carrying capacity, threatening the ability of cells and tissues to function.

Nutritional deficiencies can also contribute to chronic anemia. Vitamins such as B_{12} and folate, and minerals such as iron, are essential in RBC production. When they are deficient, the resulting RBCs may be ineffective in volume, color, quality, or quantity.

Another route leading to anemia is the rapid destruction of RBCs, or **hemolysis**. In hemolytic anemia, RBCs are destroyed faster than they can be produced. This disorder may result from genetic or extrinsic causes, including autoimmune reactions, infections, and side effects of certain medications.

Pernicious Anemia

Vitamin B_{12} malabsorption anemia, known as **pernicious anemia**, occurs due to inadequate amounts of vitamin B_{12}, a nutrient that plays a key role in producing healthy RBCs. Vitamin B_{12} deficiency often results from either an autoimmune attack against parietal cells in the stomach lining or impairment of the chief cells in the gastric lining of the stomach. Both types of cells are necessary to produce and secrete **intrinsic factor**, an essential protein needed for the absorption of vitamin B_{12} by the small intestine. Patients who undergo weight loss surgery in which parts of the stomach are excised, altering production of intrinsic factor and absorption of vitamin B_{12}, are also at risk of pernicious anemia. Symptoms of pernicious anemia include fatigue, weakness, pale skin, and neurological symptoms such as tingling and numbness in extremities.

LINK TO LEARNING

To prevent pernicious anemia, it is important to eat foods that are high in vitamin B_{12}. This fact sheet about vitamin B_{12} (https://openstax.org/r/77vitaminB12) by the National Institutes of Health includes information about this important nutrient, including daily recommended amounts and foods that are rich in the vitamin.

Folate-Deficiency Anemia

Folate, also called folic acid or vitamin B_9, is essential to the production of DNA, but it also helps RBCs form and develop. Megaloblastic anemia, or **folate-deficiency anemia**, results from inadequate levels of folate, resulting in diminished production of healthy RBCs and Hb. A common cause of this disorder is impaired DNA synthesis within bone marrow, leading to the production of abnormally large and immature RBCs (WHO, 2024). These abnormal cells

cannot transport oxygen effectively, leading to symptoms associated with anemia, including fatigue, weakness, pale skin, and tingling or numbness in the extremities. Treatment options may include changes to diet, though it may be necessary to take lifelong folate supplements.

LINK TO LEARNING

To prevent folate-deficiency anemia, it is important to eat foods that are high in vitamin B_9. This fact sheet about vitamin B_9 (https://openstax.org/r/77vitaminB9) by the Harvard School of Public Health includes information about folate, including daily recommended amounts and foods that are rich in the vitamin.

Iron-Deficiency Anemia

The mineral iron is necessary to form Hb. An **iron-deficiency anemia** arises from insufficient levels of iron in the body leading to inadequate Hb formation. This disorder may develop from inadequate iron intake, impaired iron absorption (e.g., from celiac disease or weight-loss surgery), or increased iron loss (e.g., from menstruation or gastrointestinal bleeding) (Camaschella, 2019). An iron-rich diet is key for supporting Hb production and avoiding iron-deficiency anemia. Furthermore, certain foods, such as those high in vitamin C, can facilitate iron absorption, whereas other foods, particularly those high in calcium, can inhibit it. Thus, when consuming foods with iron, it may be wise to avoid also consuming calcium-rich dairy products. Furthermore, animal sources of iron may provide more efficient absorption compared with vegetable sources.

LINK TO LEARNING

To prevent iron-deficiency anemia, it is important to eat foods that are high in iron. This iron fact sheet (https://openstax.org/r/77iron) by the National Institutes of Health includes information about iron, including daily recommended amounts and foods that are rich in the mineral.

Other Causes of Anemia

Anemia can also be caused by various autoimmune conditions and chronic diseases that affect RBC production. Cancers and cancer treatments can also lead to anemia. For example, the cytotoxic effects (i.e., harmful impacts) of chemotherapy may inhibit hematopoiesis (the process by which the body manufactures RBCs), and cancer cells often invade bone marrow or alter production of EPO in the kidneys (NHLBI, 2021). Other anemias occur as secondary effects from chronic or autoimmune diseases, such as rheumatoid arthritis, as well as those due to advanced age, chronic infection, or kidney disease can create inflammation and disrupt iron metabolism (Weiss et al., 2019).

Clinical Manifestations

Anemia's exact pathophysiology depends on its cause; however, all forms share one characteristic: an inability to provide enough oxygen to meet bodily needs, which has serious ramifications for health and well-being. Regardless of the etiology or cause, symptoms of anemia include fatigue, weakness, pallor, and shortness of breath. In more serious cases, the disorder can cause complications affecting the heart, brain, and other vital organs. People with anemia may also feel lightheaded, which can be exacerbated by position changes, and they may experience impairment of their memory or other cognitive processes.

Diagnostics and Laboratory Values

Blood tests are a foundational method of diagnosing and classifying anemia as well as other hematological conditions. They offer key insight into the RBCs and other components of a blood sample. A **hemogram** is a detailed analysis of a blood sample that examines not only the quantity of RBCs, WBCs, and platelets but also their size, color, and the percentage of iron in them. The following terms are important for understanding and interpreting a hemogram:

- The root *chromic* refers to the color of a cell.
- The root *cytic* refers to a cell.

- The prefix *micro-* signifies a size measurement that is below the normal parameter.
- The prefix *macro-* signifies a size measurement that is above the normal parameter.
- The **mean corpuscular volume (MCV)** describes the average size of an RBC.
- The **mean corpuscular hemoglobin concentration (MCHC)** describes the concentration of Hb in a single RBC.

Table 16.2 connects different types of anemia with results from a hemogram. Remember that regardless of the color and size of the RBCs, anemia is characterized by a lower-than-normal quantity of RBCs resulting in hypoxemia.

Type of Anemia	Reference Range	Laboratory Description
Microcytic anemia	• MCV: less than the reference range (typically <80 fL) • MCHC: typically within the reference range	• RBCs do not have adequate iron to fully form and are smaller than normal, indicating impaired Hb synthesis. • Common causes include iron-deficiency anemia, thalassemia, and certain chronic diseases.
Microchromic anemia	• MCV: typically within the reference range • MCHC: less than the reference range (typically <31 g/dL)	• Characterized by RBCs with reduced Hb content, often appearing pale • Can result from conditions like iron-deficiency anemia, anemia of chronic disease, and thalassemia
Macrocytic anemia	• MCV: greater than the reference range (typically >100 fL) • MCHC: typically within the reference range	• RBCs are larger than normal but have not fully formed. • Can be related to vitamin B_{12}–deficiency anemia or folate-deficiency anemia. Other causes include certain medications and bone marrow disorders.
Macrochromic anemia	• MCV: typically within the reference range • MCHC: greater than the reference range (typically >36 g/dL)	• RBCs contain excessive Hb, making them appear darker than normal. • This type of anemia is rare and can be seen in hereditary conditions like hereditary spherocytosis.
Normochromic anemia	• MCV: within the reference range • MCHC: within the reference range	• The size and Hb content of RBCs are within the normal range. • This category is broad and can encompass various types of anemia, including anemia of chronic disease, chronic kidney disease–related anemia, and early stages of some hemolytic anemias.

TABLE 16.2 Associated Laboratory Values for Different Types of Anemia (Weiss et al., 2019)

Nursing Care of the Patient with Anemia

Nursing care for individuals with anemia must be tailored according to the type and severity of the disorder, as well

as the patient's specific symptoms, needs, and circumstances. Collaboration among health-care team members and patient education are both integral in providing comprehensive care for those affected by anemia (Weiss et al., 2019).

Recognizing and Analyzing Cues

Nurses must recognize and analyze signs of anemia through a holistic assessment that encompasses both subjective and objective information. Subjective symptoms that might signal anemia include fatigue, weakness, dizziness, and shortness of breath. Nurses should actively listen to patient complaints, ask about the onset and progression of symptoms, and consider medical histories and risk factors.

Objective signs may include physical findings such as pale skin and mucus membranes and delayed capillary refill time. Nurses should look for signs of decreased perfusion in vital sign deviations, including hypotension, tachycardia, and a low pulse oximetry. A review of laboratory blood test results, such as a complete blood cell (CBC) count, will show a low Hb level. Nurses should assess for any signs and symptoms of bleeding, which include reports of increased bruising, bloody stools, bloody urine, frequent heavy menstrual cycle patterns, and problems with bloody noses or bleeding guns. A nutritional assessment can identify any dietary deficiencies.

LINK TO LEARNING

To identify anemia (https://openstax.org/r/77anemia) quickly, it is important to understand which vital signs might change and why. Recognizing changes in your patients' vital signs is the first step in critical thinking.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Once anemia has been diagnosed, stabilization of the disorder and treatment of the underlying cause are the priorities. Nursing interventions for patients with anemia depend on the underlying cause, and can include:

- administering medications to reverse interventions that caused excess bleeding, such as vitamin K to induce blood clotting and reverse an elevated international normalized ratio (discussed later in this chapter) due to high warfarin levels
- frequently assessing vital signs to monitor hemodynamic trends and symptoms due to anemia
- instituting fall precautions to reduce patient harm
- monitoring for bleeding by collecting occult stool samples, drawing blood samples for measurement of serial Hb and hematocrit (Hct) levels to monitor trends, and documenting output from any drains
- providing supplemental oxygen, as prescribed, to patients with transient hypoxia
- transfusing prescribed blood products

Patients with stable anemia are often cared for on medical-surgical floors, though they may require surgical consultations or, in worse cases, surgery to identify any bleeding. Patients with severe, symptomatic cases may require close monitoring in the intensive care unit. Once the anemia has been stabilized, the patient is likely to experience weakness. To avoid fatigue, activities of daily living should be performed in clusters, or planned rest periods should be provided between activities.

Patient education should focus on the type of anemia, its causes and effects, and the importance of following prescribed treatments. Instruct the patient on how to prevent complications and manage anemia-related symptoms. Provide education about prescribed therapies, including dietary recommendations, purposes, and medications. Include nutritional recommendations to increase oral iron intake, if necessary.

Finally, schedule follow-up appointments and laboratory tests, as necessary, to assess the patient's response to therapy, adjust interventions, and quickly report any side effects or concerns to the health-care team.

Evaluation of Nursing Care for the Patient with Anemia

Evaluation is a crucial element of nursing practice that enables nurses to assess the efficacy of nursing interventions provided to patients with anemia.

Evaluating Outcomes

To evaluate the effectiveness of nursing interventions, the desired goal must first be identified and then compared

with the outcomes. The following are examples of outcomes the nurse would evaluate for a patient with anemia:

- Blood pressure, respiratory rate, and oxygenation saturation levels have returned to target ranges.
- Neurological findings of syncope and altered consciousness are resolved and improved.
- Nutritional improvements include increasing dietary intake of vitamin B_{12}, iron, and folate.
- The patient reports improvement of symptoms, such as less fatigue and shortness of breath; the patient is able to complete activities of daily living.
- The patient reports reduced levels of pain secondary to alteration in perfusion.

Medical Therapies and Related Care

Treatment of anemia depends upon accurately diagnosing the cause, including any nutritional deficiencies involved (Mayo Clinic Staff, 2022). Appropriate therapies may include nutritional support; pharmacological support, such as RBC-stimulating agents; and, in acute or severe symptomatic presentations, blood transfusion. If anemia is a secondary effect of another health condition, like gastrointestinal bleeding or chronic inflammation disease, it will be necessary to treat that condition.

Iron supplementation is a needed treatment when iron is low, because RBCs require iron for full functioning. Oral iron supplements may be taken up to three times a day with food to boost body stores of iron and promote appropriate production of RBCs. These supplements may come in the form of ferrous sulfate, ferrous gluconate, or other iron preparations. Consuming iron with vitamin C potentiates its effectiveness, whereas taking it with calcium can delay the absorption. Caution patients that iron supplements may cause a darkened stool and some constipation. Adequate water intake is essential. Proper supplementation is also essential for pernicious anemia and folate-deficiency anemia. Folate is dosed with daily supplements or can be administered as a subcutaneous injection.

When severe symptoms or complications develop due to anemia, blood transfusion may become necessary. Donated blood can quickly replace depleted RBC counts. EPO therapy stimulates RBC production from bone marrow. Recombinant human EPO may be prescribed to those experiencing anemia caused by chronic kidney disease or cancer treatments like chemotherapy. Medications, such as darbepoetin alfa and epoetin alfa, may help stimulate bone marrow to produce more RBCs by acting on the bone marrow. Bone marrow stimulants are commonly administered subcutaneously to patients who are dialysis dependent.

16.2 Hereditary Disorders

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations associated with hereditary hematological disorders
- Describe the diagnostics and laboratory values of hereditary hematological disorders
- Apply nursing concepts and plan associated nursing care for the patient with a hereditary hematological disorder
- Evaluate the efficacy of nursing care for the patient with a hereditary hematological disorder
- Describe the medical therapies for hereditary hematological disorders

Hereditary blood disorders include sickle cell anemia and thalassemia. These inherited disorders disrupt the structure, function, or production of Hb, the protein that transports oxygen in RBCs. These disorders have an enormous effect on individuals and their families, often necessitating lifelong medical treatment and management. Understanding the genetic mechanisms, clinical manifestations, and treatments available for hereditary blood disorders is important for health-care professionals because they play an essential part in diagnosing, caring for, and supporting those who have these chronic conditions.

Sickle Cell Anemia

An inherited blood disorder caused by abnormal Hb production that results in RBCs forming into crescent-shaped "sickles" is called **sickle cell disease**. Of the many types of sickle cell diseases, the one that causes severe anemia is called **sickle cell anemia (SCA)**. Like other sickle cell diseases, SCA is characterized by abnormal production of Hb caused by a genetic mutation; in the case of SCA, however, RBCs become rigid and sticky before taking on their

characteristic crescent shape (sickle). As a result, the RBCs block vessels and may eventually prevent blood from reaching organs (Figure 16.2). SCA most often affects individuals of African, Mediterranean, Middle Eastern, or South Asian descent; presents as acute pain crises or long-term organ damage; and affects mortality and morbidity.

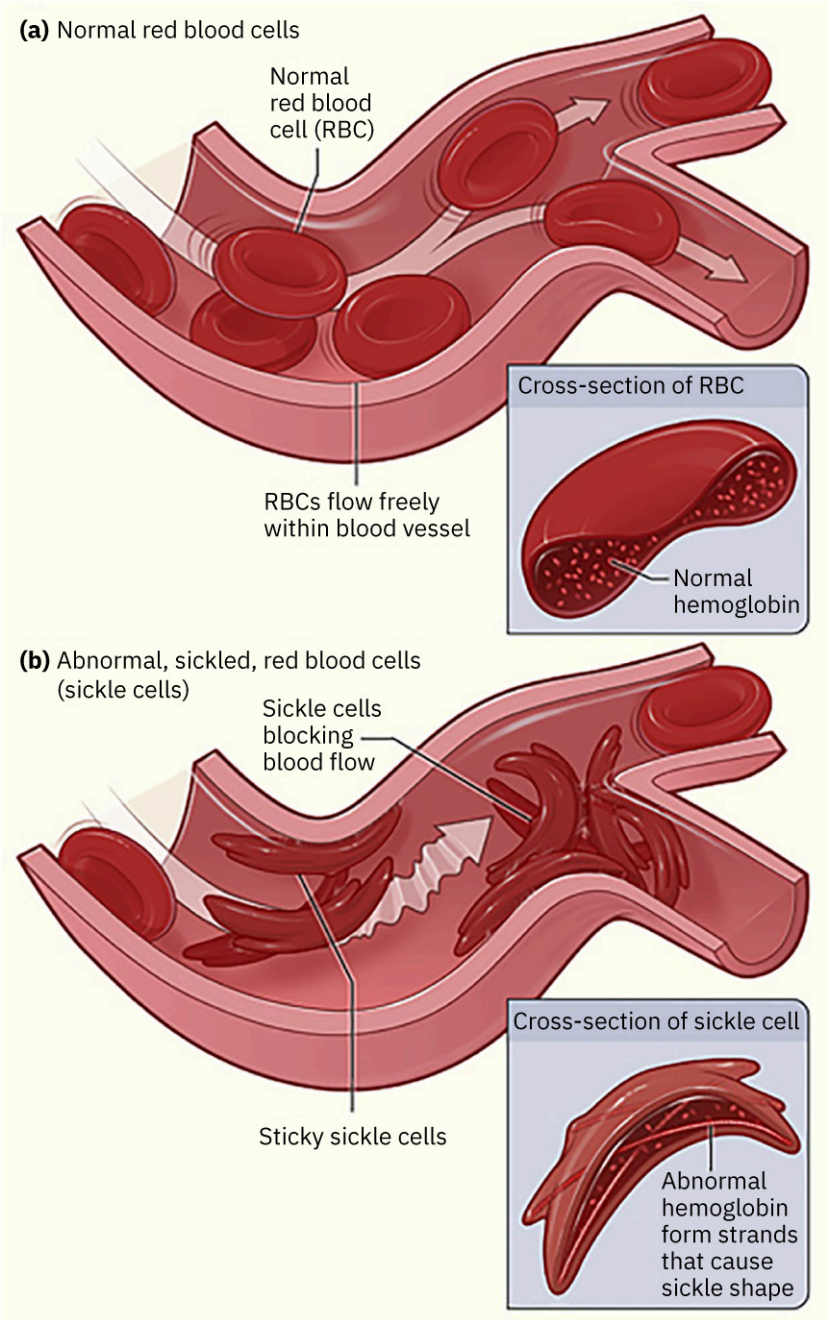

FIGURE 16.2 (a) Normal red blood cells (RBCs) are circular with healthy hemoglobin protein, and freely flow through the blood vessels carrying oxygen. (b) In SCA, RBCs take on a sickle shape from abnormally formed hemoglobin and become sticky, preventing them from freely flowing through the blood vessels and successfully transporting oxygen throughout the body. (credit: The National Heart, Lung, and Blood Institute/Wikimedia Commons, Public Domain)

Clinical Manifestations

SCA clinical manifestations vary significantly from patient to patient. Generally, they are like symptoms for other kinds of anemia, but the resulting pain may be worse, particularly during a **vaso-occlusive crisis**. Also known as a pain crisis or sickle cell crisis, this is when sickle-shaped RBCs block circulation through small vessels, causing tissue ischemia, which can lead to infection and permanent tissue damage. SCA also increases the risk for stroke among children, because of smaller blood vessels. Effective management of SCA generally includes pain management, blood transfusions, medication (e.g., hydroxyurea), and sometimes bone marrow or stem cell

transplantation. People living with SCA require lifelong medical supervision to control symptoms and avoid complications.

It is important to distinguish between having SCA and being in a sickle cell crisis. People with the genetic abnormality for sickle cell disease may be asymptomatic for years until a crisis occurs, which often is due to another issue, such as an infection, trauma, accident, or emotional upset. Crises may also be caused by conditions that create a demand for more RBCs, such as high altitude or strenuous exercise (Mangla et al., 2023). Clinical manifestations of SCA include

- damage to the organs such as the spleen, heart, lungs, and kidneys
- delayed growth and development, seen mostly in children, due to tissue hypoxemia and hypoxia
- fatigue from hypoxemia due to ineffective RBCs
- frequent infections from poor blood flow due to clogged vessels from sickled cells
- leg ulcers from poor blood flow to lower limbs
- pain
- presenting as a yellow hue to the skin, **jaundice** results from the body breaking down RBCs, releasing the heme portion
- swelling of hands and feet, that may be identified in childhood, often called "hand-foot syndrome" or **dactylitis**

Note that severity and frequency of signs and symptoms can differ for every individual with SCA (Mangla et al., 2023).

REAL RN STORIES

Nurse: Ramon
Years in Practice: Ten
Clinical Setting: Step-down progressive care unit
Geographic Location: Hartford, Connecticut

One challenging night shift in the emergency department [ED], I was tending to Jamal, a 25-year-old patient, who was experiencing an intense sickle cell crisis. Jamal had frequently visited the ED due to sickle cell anemia. I entered his room and heard muffled groans of pain from his bedside. Upon reviewing his medical history, I recognized his past struggles with pain crises and quickly started an assessment gathering vital signs and recognized the need for immediate pain relief. Jamal described increasing discomfort in his joints and back. I tried to maintain a calm and caring demeanor by acknowledging his discomfort and administering medication to alleviate his joint pain. Recognizing that repeated crises take an emotional toll, I engaged Jamal in conversation by sharing stories and inviting him to open up about his experiences. I observed nonverbal signals of anxiety and distress in our dialogue. Responding to his needs, I adjusted his positioning, provided warm blankets, and collaborated closely with the health-care team and hematologist on call to ensure he received high-quality treatment and multidimensional support. Together, we discussed Jamal's treatment plan, reviewed his medical history, and considered long-term adjustments in management.

I remained with Jamal throughout the night and monitored his response to interventions, dispensed medications promptly, and offered emotional support as necessary. Over time, Jamal's pain started subsiding. I was profoundly moved by this experience and realized the significance of not only treating physical symptoms of sickle cell disease but also considering psychological and emotional aspects that play such an integral part in the patient's journey. It was an eye-opening experience for me because it demonstrated just how profound and impactful a holistic nursing approach can be when helping someone manage chronic conditions like sickle cell anemia.

Diagnostics and Laboratory Values

The following laboratory and diagnostic tests can be used during the diagnostic process, as well as for continued monitoring of the sickle cell condition:

- A **bone marrow aspiration** is used to verify SCA by measuring the production of RBCs in the bone marrow. It

is often performed alongside a bone marrow biopsy.

- A **complete blood count (CBC)** measures the amount of RBCs, WBCs, and platelets in a blood sample. SCA often presents with low RBC counts.
- A **total bilirubin test** measures how much bilirubin is being released into the bloodstream. SCA causes destruction of RBCs faster than they can be created. This causes strain on the liver and can result in the liver releasing bilirubin into the patient's system, causing jaundice in some instances.
- Genetic testing can verify specific mutations associated with SCA and is often used for prenatal counseling to determine whether individuals are carriers for the disease.
- A **hemoglobin solubility test** quickly screens for sickle Hb detection, offering results in minutes. Blood samples are mixed with a reducing agent to inactivate Hb and form characteristic crystals. In positive results, there would be presence of hemoglobin S (Hb S) and sickling Hb.
- A **hemoglobin electrophoresis** can diagnose SCA by distinguishing different forms of Hb to detect the form and characteristics of sickle-shaped RBCs.
- A **peripheral blood smear** enables analysis of RBC shape and condition for diagnostic purposes. SCA is characterized by RBCs with characteristic sickle-shaped membranes.
- A **reticulocyte count** measures the number of young RBCs in a blood sample. As a compensatory mechanism in SCA, bone marrow produces more young RBCs into circulation than normal to replace short-living RBCs, leading to an elevated reticulocyte count.

Thalassemia

A group of hereditary blood disorders that affect the Hb genes, leading to decreased **erythropoiesis**, or Hb production, is referred to as **thalassemia**. Thalassemia mostly affects people of Mediterranean, Asian, or African descent (Mangla et al., 2023). Thalassemia can be one of the more devastating blood disorders to encounter, with symptoms ranging in severity from mild anemia to life-threatening conditions that necessitate ongoing medical intervention. Therefore, understanding its genetic, clinical, and treatment aspects is of utmost importance for providers (Bajwa & Basit, 2023).

Clinical Manifestations

Normal adult Hb is made up of two alpha and two beta protein chains. Thalassemia results from defects in Hb production. Alpha-thalassemia is a deletion of one or more of the a-globin producing genes, and beta-thalassemia is a deletion of one or more of the b-globin producing genes (Bajwa & Basit, 2023). Affected individuals may experience fatigue, weakness, pale skin tone, and shortness of breath due to insufficient oxygen-carrying capacity in their blood supply. In severe cases, it may manifest through symptoms including splenomegaly, jaundice, and bone deformities. Some individuals can remain asymptomatic carriers, whereas others require regular blood transfusions and medical monitoring.

Diagnostics and Laboratory Values

Thalassemia can be identified through specific patterns that depend upon its type (alpha or beta) and severity, as well as the frequency of transfusions necessitated by the disorder. The difference between the types is that alpha thalassemia necessitates blood transfusions in early childhood and rates of fatality at birth are higher (Barid et al., 2022).

Laboratory and diagnostic tests for thalassemia are very similar to those done for SCA. A few key tests that are used to diagnose the disorder's type (genetic karyotyping) and disease severity are the following:

- A CBC count assesses both the quantity and quality of blood cells. Thalassemia often presents with anemia, with low levels of Hb, RBCs, and Hct.
- Hemoglobin electrophoresis is a test for identifying different types of Hb present in a blood sample and identifying any mutations. Some types of Hb include:
  - hemoglobin A and A2: adult hemoglobin
  - hemoglobin F: fetal hemoglobin; found in fetuses and is replaced by hemoglobin A shortly after birth
  - hemoglobin E, S, C, H, and M: abnormal Hb caused by genetic mutations
- Thalassemia may lead to increases in hemoglobin A2 as well as hemoglobin F. Quantifying these components in a blood sample helps accurately diagnose thalassemia.
- Iron studies may reveal altered iron levels in a patient with thalassemia due to frequent blood transfusions.

Ferritin levels and iron concentration in the blood can be measured to detect iron overload.

- A peripheral blood smear examination provides information regarding the size, shape, and color of RBCs present in a specimen. Thalassemia can be identified by hypochromic and microcytic RBCs.
- Genetic testing can detect specific mutations of globin genes to confirm diagnosis and provide more details on the Hb type.
- If necessary, a bone marrow biopsy specimen can be collected and used to help evaluate RBC production within bone marrow to confirm a diagnosis and establish treatment plans such as blood transfusions or iron chelation therapies. Regular monitoring through this testing process is crucial in managing thalassemia effectively.

Nursing Care of the Patient with a Hereditary Hematological Disorder

Nursing care for patients living with hereditary hematological disorders must incorporate both physical and emotional needs to treat patients holistically. Nurses play a pivotal role in providing necessary treatments such as blood transfusions or iron chelation therapy (discussed in detail in Medical Therapies and Related Care), monitoring dosage accuracy, and tracking potential adverse reactions. Patient education is crucial to helping individuals and their families understand the nature of hereditary disorders, the pros and cons of available treatment modalities, and the importance of taking all prescribed medication per the prescribed schedule. Essentially, the main goals of preventive measures for patients with SCA and thalassemia are to manage symptoms, reduce complications, and improve the overall quality of life.

Recognizing Cues and Analyzing Cues

To recognize and understand SCA and thalassemia, nurses must use their clinical assessment skills, review patient histories, and comprehend each disorder's specific manifestations. Regularly monitoring vital signs and reviewing CBC counts and specific markers relating to each disorder can help nurses identify the status of the condition. Other parameters nurses are responsible for monitoring include hydration status and vaccine compliance, because dehydration and infection can trigger an exacerbation. The nurse should also help the patient identify any potential provoking factors, such as temperature variations. Additionally, collaborative communication between health-care teams as well as ongoing education of both the patient and their caregivers are integral parts of ensuring comprehensive care for individuals living with these conditions. Cues are found in the nursing health history assessment, physical assessment, laboratory results, and even psychosocial assessment. These cues help nurses obtain the relevant objective and subjective data, analyze these data, and create a nursing diagnosis and care plan.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Primary prevention is a main goal for patients with thalassemia and SCA. Nurses can identify a vaso-occlusive crisis in a patient with sickle cell disease by recognizing early dehydration or signs of infection, and then help manage pain with adequate hydration and analgesics. In acute exacerbations of sickle cell crisis, hydration with intravenous (IV) fluid replacement may be required, along with analgesics (predominantly IV opioids) to assist with pain control. In acute exacerbations of thalassemia, interventions differ in that nurses may have to administer a blood transfusion or iron chelation therapy—treatments that assist with binding to excess iron and maximize elimination. If anemia causes tissue hypoxia, the nurse can support oxygenation. For all patients with anemia, patient and family education needs to be given to empower them with better understanding of the causes, risk factors, and treatment plan for their disorder.

After tertiary interventions have been implemented, secondary prevention measures are necessary to avoid future exacerbations. Patients with SCA are encouraged to identify triggers. Promotion of adequate hydration, vaccine compliance, regular medical check-ins, and avoidance of extreme temperature fluctuations are all important elements to consider when educating patients. Patients with thalassemia are recommended to receive surveillance of Hb levels, iron studies, and whole-blood hemograms to ensure an exacerbation is not imminent. Patients with thalassemia or the trait for it may require genetic counseling when interested in pursuing family planning.

To provide holistic nursing, patients with sickle cell disease or thalassemia require further support in addition to the physical burdens. Emotional support should also be offered because these conditions typically require lifelong management. Nurses are part of the health-care teams that develop customized care plans tailored specifically to each hematological disorder, taking into account each person's specific needs and challenges. Furthermore, nurses promote preventive measures while encouraging patients to actively take part in their treatment, instilling control

and well-being amid chronic hereditary conditions.

CLINICAL SAFETY AND PROCEDURES (QSEN)

Patient-Centered Care: Care of the Patient with Sickle Cell Crisis

Patients with sickle cell disease are often at risk for vaso-occlusive crisis. Primary prevention is aimed at staying hydrated and avoiding infection by complying with vaccination recommendations. In an acute crisis, perfusion and pain are the main clinical concerns. Due to the aggregation of sickling RBCs, patients with a vaso-occlusive crisis require hospitalization, telemetry, IV fluids, and pain management. Although this disorder is usually diagnosed in the pediatric population, adults can learn how to manage with transitional programs. Community partnership and outreach with nursing support have shown promising outcomes to assist patients with sickle cell disease.

Evaluation of Nursing Care of the Patient with a Hereditary Hematological Disorder

Evaluating nursing care for patients diagnosed with hereditary hematological disorders involves an ongoing, systematic process designed to measure both intervention effectiveness and overall patient well-being. Some examples include preventing bleeding-related injuries and evaluating the patient understanding of the need to continue this practice in their daily life. Another example is promoting good skin integrity. The integrity of the skin becomes paramount to prevent wounds that may lead to bleeding complications.

Evaluating Outcomes

The nurse can evaluate patient outcomes by comparing them with initial goals set for the patient and assessing for symptom improvement. Regularly monitoring laboratory results can help the nurse compare changes against a baseline condition. For example, in patients with thalassemia, a Hb level greater than 9 g/dL would indicate that treatment was working (Bajwa & Basit, 2023). Pain management for a patient with SCA should be evaluated as early as 15 minutes after administration of pain medication and then hourly. For patients with chronic anemia, nurses should assess patient adherence to the treatment plan, including medications, blood transfusions, iron chelation therapy, or other therapeutic interventions. Collaborating with the health-care team can help the nurse evaluate patient outcomes through communication of progress with the allied health-care team.

Medical Therapies and Related Care

The treatment approach for hereditary hematologic disorders often centers on managing symptoms, avoiding complications, and improving overall quality of life. Treatment methods will depend on both the type and severity of the disorder. In acute phases, pain management with IV analgesics is common. Also, IV fluid therapy may be indicated to alleviate a vaso-occlusive crisis.

In chronic management, other conservative therapies exist. One medication is hydroxyurea, which increases the production of hemoglobin F. This makes RBCs larger, rounder, and more flexible, preventing sickle cells from forming. Bone marrow transplantation may be considered for severe cases of hereditary hematologic diseases like thalassemia; replacing defective bone marrow with healthy donor material may provide curative options. Folate supplements may support RBC production for those diagnosed with anemia (including thalassemia). Other treatments include regular blood transfusions to combat anemia and improve oxygen-carrying capacity of blood.

A treatment called **iron chelation therapy** is an effective method of eliminating excess iron from the body, especially among individuals receiving frequent blood transfusions that have caused the buildup of excess iron. Iron chelators are medications designed to bind to excess iron in the bloodstream, creating a compound that can then be expelled from the body through excretion. This helps avoid iron overload, which, if untreated, can result in organ damage (Kwiatkowski, 2023).

16.3 Polycythemia

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations associated with polycythemia
- Describe the diagnostics and laboratory values in polycythemia
- Apply nursing concepts and plan associated nursing care for the patient with polycythemia
- Evaluate the efficacy of nursing care for the patient with polycythemia
- Describe the medical therapies for the care of polycythemia

A hematologic condition marked by an abnormal increase in the number of RBCs in the body is called **polycythemia**. This condition can be primary (genetic) or secondary (caused by other diseases or conditions, such as chronic lung disease, kidney disease, cardiopulmonary shunts) (Haider & Anwar, 2023). Polycythemia increases the blood's viscosity (thickness), resulting in complications including blood clots, cardiovascular issues, and reduced circulation. When caring for patients with polycythemia, the primary objectives are to identify its underlying causes, take appropriate diagnostic steps, and devise tailored management strategies to minimize potential risks while increasing overall well-being for patients.

Pathophysiology of Polycythemia

The pathophysiology of polycythemia can be divided into two major subcategories: primary and secondary. Primary polycythemia, or **polycythemia vera**, is a myeloproliferative disorder, which means it originates from the bone marrow (Pillai et al., 2023). A genetic mutation causes an abnormal response to the hormone EPO, an important hormone that stimulates RBC production from the kidneys, causing erythropoiesis (RBC production) to increase independently of the body's natural regulatory mechanisms (Pillai et al., 2023). Overproduction of RBCs increases blood viscosity, impairing blood flow and increasing the risk for thrombosis, stroke, or myocardial infarction.

When EPO stimulation occurs as an adaptive reaction to other conditions, **secondary polycythemia** occurs. Recall that EPO (erythropoietin) is normally released by the kidneys as a response to low oxygen levels in blood. The abnormal release triggers the bone marrow to increase RBC production. This can lead to impaired blood flow, with potential complications including stroke or myocardial infarction. Conditions that can trigger secondary polycythemia include chronic hypoxia from respiratory or cardiovascular illnesses, congenital heart disease, and certain tumors such as renal cell carcinoma. Smoking and living at high elevation can also trigger excess RBC production.

Primary and secondary polycythemia both can result in complications arising from increased blood viscosity, making it imperative that its root causes be addressed to reduce any risk for thrombotic events. Treatment strategies may include phlebotomy to lower RBC counts, medication to address symptoms, and management of any secondary conditions underlying polycythemia. An interdisciplinarian team approach is key to optimize management and avoid possible complications related to polycythemia.

Clinical Manifestations

Clinical presentation of polycythemia varies from patient to patient. Symptoms may be nonspecific and may include fatigue, headache, and dizziness (Haider & Anwar, 2023). If large vessel occlusion occurs due to clumping of excess blood cells, symptoms will result in the occluded vessel. For example, if viscous blood clumps and creates a clot in a coronary artery, the patient may report chest pain, shortness of breath, fatigue, or nausea. If a clot develops in a brain artery, the patient may experience weakness (generalized or one sided), visual changes, or difficulty with speech.

Diagnostics and Laboratory Values

Diagnosing polycythemia requires performing various laboratory and diagnostic procedures that assess RBC counts as well as determine their source. Primary polycythemia often results in lower or normal EPO levels, while secondary polycythemia usually causes an increase. The following tests are used to help diagnose either type of polycythemia:

- A CBC count identifies Hb and Hct levels and compares them with the normal ranges. It also measures RBCs.
- Bone marrow aspiration and biopsy may be performed to evaluate the composition of blood cells as well as

rule out other conditions that may exist in the bone marrow. Primary polycythemia affects bone marrow with increased cell volume due to increased RBC precursors.

- For accurate detection of primary polycythemia, genetic tests must look specifically for *JAK2* mutations. An extensive diagnostic approach is key to distinguish primary from secondary polycythemia and provide appropriate management strategies.
- A simple pulse oximeter can measure the presence of hypoxia, which can stimulate RBC production and lead to secondary polycythemia.
- Chest x-rays and computed tomography (CT) scans can help identify lung diseases or tumors, which may be a cause of secondary polycythemia. Ultrasound or magnetic resonance imaging visual tests can also identify organ enlargement, such as of the spleen or liver, resulting from polycythemia.
- An arterial blood gas analysis can give information about blood pH and oxygenation. These data can help identify secondary causes of polycythemia, which may be causing the body to produce more RBCs.
- The cause of a thrombotic event can be identified by testing for clotting factors and blood components.

An extensive diagnostic approach is key to distinguishing primary from secondary polycythemia and providing appropriate management strategies. Patients suspected of polycythemia should undergo extensive evaluation by health-care providers.

Nursing Care of the Patient with Polycythemia

Nurses play an invaluable role in recognizing and interpreting signs in patients experiencing polycythemia. Through diagnostic studies, the nurse can recognize the overproduction of RBCs. Nursing actions include monitoring vital signs and clinical manifestations, completing a physical exam, and administering ordered treatments.

Recognizing and Analyzing Cues

By completing vital signs and a thorough head-to-toe assessment, nurses can recognize cues from each body system suggesting the existence of polycythemia (Table 16.3). A subjective assessment may include the patient stating feelings of fatigue, early satiety (feeling full), abdominal pain, inactivity, problems with concentration, night sweats, pruritus, bone pain, weight loss, and fever. Elevations in Hb, Hct, and EPO levels are particularly important when identifying polycythemia. Additional cues may be obtained from a thorough patient history, which should include questions about the patient's history of smoking and altitude exposure.

System	Symptoms
General	Fatigue
Integumentary	Erythromelalgia (redness and a burning sensation), often of hands and feet Pruritus (itching) due to histamine release
Neurologic	Headache Visual disturbances, sometimes resulting in dizziness or disorientation Cognitive changes due to poor blood flow to the brain
Hematologic	Easy bruising and bleeding Increased occurrence of blood clots
Cardiovascular	Hypertension Peripheral edema caused by increased blood flow congestion
Respiratory	Dyspnea (shortness of breath)
Gastrointestinal	Hepatomegaly or splenomegaly due to increased blood volume

TABLE 16.3 Body Systems Affected by Polycythemia

System	Symptoms
Renal	Increased urine flow due to increased blood volume
Musculoskeletal	Joint pain

TABLE 16.3 **Body Systems Affected by Polycythemia**

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Acute management of polycythemia centers around treating the cause, if possible; preventing thrombotic events due to the overproduction of RBCs; and symptom improvement. Dependent on the degree of symptoms, nursing interventions are tailored to the patient's presentation (Brennan-Cook, 2020).

LINK TO LEARNING

The Oncology Nursing Society endorses the MPN Symptom Assessment Form Total Symptom Score (MPN-SAF TSS) (https://openstax.org/r/77MPNassess) tool. This allows patients to track symptoms to report to the nurse and health-care team, who can then evaluate the severity of symptoms and create an effective plan of care.

Ultimately, nurses assist patients with symptom control and reduction of thrombotic risk (Lu & Chang, 2023). Education is important. For example, the patient might be taught to slowly increase their activity level in alignment with their fatigue. If night sweats are a sign, nurses can educate patients to identify triggers (e.g., alcohol, spicy food, caffeine) and to adjust their intake accordingly. For early satiety, nurses can help patients plan a diet that is heart healthy and high in protein, whole grains, fruits, and vegetables. For severe pruritus, nonpharmacological remedies such as cool showers and skin moisturizers are recommended. Patients with brain fog or difficulty concentrating may require pharmacological therapy, including additional education on the purposes of these medications. Given the propensity for infection, identification of fevers that deviate from target temperature parameters and a comprehensive workup may be indicated (Brennan-Cook, 2020).

Evaluation of Nursing Care for the Patient with Polycythemia

Evaluation of nursing care for polycythemia centers around symptom management and tailoring interventions and care plans specifically to address each patient's unique needs. It is important to perform regular assessments to evaluate how interventions affect symptom improvement.

Evaluating Outcomes

A continuous evaluation process is crucial to improving care delivery, avoiding complications, and supporting overall health and well-being for each patient. Stabilization of an acute exacerbation and/or avoiding a thrombotic event are ideal outcomes, but there are specific outcomes nurses may identify (Pillai et al., 2023), including:

- A reduction of self-reported physical symptoms and objective signs help the nurse assess for changes or improvements, which can dictate next steps.
- The stabilization or normalization of RBCs, Hb, and Hct, and comparing the current results with previous results.
- The patient can articulate importance of compliance with pharmacological therapy, and verbalizing signs and symptoms of a thrombotic event.
- The patient can report reduced anxiety and depression and identify healthy coping mechanisms. Evaluating the patient's social support system can also help identify what resources will be needed.
- The patient maintains target parameters for oxygen saturation, heart rate, and blood pressure.

Medical Therapies and Related Care

The goal of medical management of polycythemia is to lower RBC counts, prevent complications such as thrombosis, and improve overall symptoms. The following are major therapies for patients with polycythemia:

- A **therapeutic phlebotomy** is the removal of excess RBCs by reducing overall blood volume. If the patient has

no genetic concerns or other comorbidities, the removed blood may be donated to a blood bank or service. The frequency and quantity of each reduction is determined by the Hb and Hct levels (Pillai et al., 2023).
- Management of cardiovascular risk factors includes management of hypertension and anticoagulation. Maintaining blood pressure at an ideal level is critical for minimizing cardiovascular events, and cholesterol management helps mitigate cardiovascular risks (Pillai et al., 2023).
- Medications such as ruxolitinib, an immune modulator, specifically target the abnormal JAK2-signaling pathway associated with polycythemia vera. Hydroxyurea is a myelosuppressive medication to decrease RBC production; interferon-α may also be used. Low-dose aspirin therapy helps decrease the risk of thrombosis by inhibiting platelet aggregation (Pillai et al., 2023).
- Regular monitoring and assessment via blood tests, including CBC counts, are used to track Hct levels and adjust treatment accordingly. Imaging studies may also be performed periodically to measure liver and spleen sizes as well as assess for potential complications (Pillai et al., 2023).
- Smoking cessation is another important strategy for patients with polycythemia because nicotine can exacerbate polycythemia's complications significantly. Smoking cessation should be pursued immediately to decrease these effects (Pillai et al., 2023).

Treatment decisions should take into consideration factors such as a patient's age, overall health status, and risk factors, as well as their response to previous interventions. Individualized treatment plans for patients with polycythemia must be created in conjunction with hematologists or health-care providers specializing in blood disorders. Their ongoing monitoring and adjustments are integral to managing this condition effectively and avoiding potential complications.

16.4 Thrombocytopenia

LEARNING OBJECTIVES

By the end of this section, you will be able to:
- Discuss the pathophysiology, risk factors, and clinical manifestations associated with thrombocytopenia
- Describe the diagnostics and laboratory values in thrombocytopenia
- Apply nursing concepts and plan associated nursing care for the patient with thrombocytopenia
- Evaluate the efficacy of nursing care for the patient with thrombocytopenia
- Describe the medical therapies for thrombocytopenia

Low platelet count syndrome, or **thrombocytopenia**, is an uncommon hematologic condition characterized by decreased numbers of platelets (thrombocytes) in the bloodstream, affecting three out of 100,000 people yearly in the United States (NORD, 2022). Platelets play an essential role in **hemostasis**, which is the physiological process that prevents and controls bleeding. Individuals with thrombocytopenia may have increased risk for bleeding as their platelet count decreases, resulting in difficulty creating blood clots and controlling hemostasis. Thrombocytopenia may either present as its own condition or be the result of other medical issues, including autoimmunity disorders, infections, or adverse drug reactions. The disorder may range in severity from mild cases with minimal symptoms to those posing significant risks of spontaneous bleeding. Management and treatment approaches depend upon the cause, level of platelet reduction, and associated symptoms. Consequently, early diagnosis and effective monitoring are key to providing optimal health-care services to patients with thrombocytopenia.

Pathophysiology of Thrombocytopenia

Platelet production is triggered in bone marrow by **thrombopoietin**, a protein released by the liver. Thrombocytopenia can have many causes: from bone marrow disorders that impair production of platelets, such as leukemia and myelodysplastic syndromes, to diseases that disrupt platelet survival over time. Immunological mechanisms may contribute to platelets being destroyed by the immune system and lead to immune thrombocytopenic purpura (ITP). Other causes include various infections, hereditary disorders, and overuse of certain medications, such as aspirin or heparin. Liver damage, from excessive alcohol intake, for example, can also cause a decrease in viable platelets, due to lower levels of thrombopoietin being produced by the liver.

Pathophysiology often includes disruption in the delicate equilibrium among platelet production, circulation, and removal, leading to fewer platelets in the bloodstream. The normal range of platelets for males and females is 150,000–400,000/μL blood) (NORD, 2022). Clinical manifestations can range from petechiae (pinpoint-sized spots

on the skin) and bruising to more serious conditions like gastrointestinal or intracranial bleeding. Prompt recognition, thorough diagnostic evaluation, and targeted interventions are crucial for effectively managing thrombocytopenia and mitigating its risks of bleeding complications in affected individuals (Nicolas et al., 2023).

Heparin-Induced Thrombocytopenia

An immune-mediated side effect caused by exposure to heparin products is known as **heparin-induced thrombocytopenia (HIT)**. HIT is characterized by a drop in platelet count and an increase in blood coagulability, which can manifest anytime from 1 to 14 days after exposure to heparin (Nicolas et al., 2023). An exaggerated immune response occurs due to antibodies produced against complexes composed of heparin and platelet factor 4 (PF4) proteins released by activated platelets. When heparin binds with PF4 proteins, an immune response triggers the production of antibodies, which attach themselves directly onto platelet surfaces, activating platelets to clot. This causes the platelet count to drop because they die off before they can be reproduced in the bone marrow. Because of its late onset in some instances, HIT may go unrecognized if a patient is discharged; therefore, occurrence may be difficult to detect.

LINK TO LEARNING

Learn more about the pathophysiology, diagnosis, and treatment of heparin-induced thrombocytopenia (https://openstax.org/r/77hepthrom) in this video.

Clinical Manifestations

HIT typically manifests as swelling at multiple points on the body surface, as the result of blood clot formation following the activation of PF4. HIT can be identified by an acute drop in platelet count, usually below 150,000 microliters; in severe cases, this can be as low as 50,000 microliters. Although most individuals with HIT do not experience bleeding directly, its adverse effect is an increased risk of arterial and venous thrombosis and subsequent arterial and venous clot formation resulting from hypercoagulability. These conditions may result in deep vein thrombosis (DVT), which is a type of venous thromboembolism; pulmonary embolism (PE); and potentially life-threatening conditions such as stroke or myocardial infarction (Nicolas et al., 2023). Because blood interacts with all tissues of the body, all organs and body systems may be affected, as shown in Table 16.4.

System	Symptom
General	Fatigue
Integumentary	Ischemic limb necrosis and necrotic lesions Swelling and edema Warmth of skin in thrombotic areas
Neurologic	Anxiety, if there is a pulmonary embolism Headache, dizziness, cognitive changes, and disorientation from poor blood flow to the brain
Hematologic	Increased blood clotting vs bleeding
Cardiovascular	Hypotension
Respiratory	Dyspnea (shortness of breath)
Gastrointestinal	Abdominal tenderness

TABLE 16.4 HIT Symptoms by Systems

System	Symptom
Renal	Hematuria
Musculoskeletal	Joint pain

TABLE 16.4 HIT Symptoms by Systems

Diagnostics and Laboratory Values

Blood tests for markers related to hypercoagulability are used to diagnose HIT. A "4-Ts" scoring system is commonly used to estimate risk potential of disease; 4-T scores less than 3 indicate a low probability for developing HIT (Lindholm & Perrotta, 2023). The four "Ts" assess degree of thrombocytopenia, thrombocytopenia timing, thrombosis, and thrombocytopenic cause. Additionally, laboratory tests such as enzyme-linked immunosorbent assays, as well as serotonin release assays can confirm antibodies specific for HIT.

Idiopathic Thrombocytopenic Purpura

More frequently referred to as immune thrombocytopenia, **idiopathic thrombocytopenic purpura (ITP)** is an autoimmune condition marked by an abrupt and significant drop in platelet count, leading to increased risks of bleeding and anemia. With ITP, the immune system erroneously recognizes platelets as foreign and produces antibodies to destroy them in the spleen and liver, which are key organs for filtering blood. Children typically experience acute ITP; in contrast, adult-onset ITP typically manifests chronically and requires ongoing management.

Clinical Manifestations

ITP may be related to other autoimmune disorders; therefore, it is important for providers to conduct a comprehensive evaluation and follow-up for patients exhibiting signs of ITP. Clinical presentation includes uniquely notable petechiae. Large, discolored, purple areas called **purpura** may also be seen on the body, due to internal bleeding. Ecchymosis and spontaneous bleeding from mucous membranes, gums, nosebleeds, and even the intestines may occur, resulting in nausea and vomiting.

Diagnostics and Laboratory Values

Laboratory and diagnostic tests for ITP are similar to those for other types of thrombocytopenia. They include measuring CBC and platelet counts, as well as autoimmune antibodies to rule out other autoimmune conditions (Nicolas et al., 2023). Additional tests such as a bone marrow biopsy can help identify bone causes of thrombocytopenia and distinguish the etiology from the other types.

Alcoholic Thrombocytopenia

A condition in which excessive alcohol consumption results in decreased platelet count in the blood is known as **alcoholic thrombocytopenia**, which leads to decreased clotting mechanisms and increases the risk for bleeding and bruising. Chronic alcohol consumption can impair platelet production from bone marrow and has other consequences, direct and indirect, on platelet production and function. Alcohol abuse is one of the main contributors of liver diseases such as alcoholic liver disease and cirrhosis. Given the importance of liver cells to platelet storage, liver damage from alcohol abuse can contribute to thrombocytopenia by disrupting clotting factor synthesis and thrombopoietin. Moreover, alcoholic thrombocytopenia is compounded by nutritional deficiencies in folate, thiamine, and vitamin B_{12} (Silczuk & Habrat, 2020).

Clinical Manifestations

Alcohol abuse often manifests with signs of thrombocytopenia that include easy bruising and petechiae, along with prolonged bleeding from minor injuries. With advanced liver disease, thrombocytopenia can be enhanced through the development of esophageal varices, which are dilated veins that generate under the mucosa of the lower esophagus and gastrointestinal tract, making the patient at risk for hemorrhage (Meseeha & Attita, 2023). Other symptoms include nose bleeds, bleeding gums, or prolonged bleeding times after minor invasive procedures (Silczuk & Habrat, 2020).

Diagnostics and Laboratory Values

Diagnostic tests are the same as for the other two types of thrombocytopenia; however, a careful social history of

the patient may reveal alcohol use disorder, which can help clarify the cause of thrombocytopenia. Management then includes the same medical treatments, with the addition of patient education and support and resources to decrease alcohol consumption.

Nursing Care of the Patient with Thrombocytopenia

Nursing care for the patient with thrombocytopenia focuses on avoiding bleeding complications, creating a safe environment, and supporting overall patient well-being. Nurses should monitor laboratory tests and vital signs, administer medication, take safety precautions, and educate the patient about their condition. Effective communication and collaboration between the patient and members of the health-care team are crucial in optimizing treatment of this disorder and increasing overall quality of life for everyone affected by it.

REAL RN STORIES

Nurse: Sarita
Years in Practice: 2
Clinical Setting: Oncology
Geographic Location: Dallas-Fort Worth, TX

I was working in a bustling oncology unit and my patient was a middle-aged male who had leukemia with severe thrombocytopenia. He needed platelet transfusions twice daily to address his low count. He had a continuous nosebleed and we worked so hard to supply him with towels. His laboratory results had been declining for several days until his platelet count dropped to 2! I recognized his life-threatening situation and tirelessly advocated on his behalf for comfort and wellness. I worked closely with the health-care team to coordinate timely platelet transfusions and provide meticulous care.

Despite our efforts, the medical team knew the outcome was not going to be good. I recognized the emotional toll the patient's illness was taking on both him and his family. I answered his questions with empathy during difficult conversations. Unfortunately, he succumbed to complications associated with his condition. I was profoundly moved by his death and offered support for his loved ones through their grief process. I focused on providing holistic, patient-centric care despite difficult circumstances. I also learned to value my own platelets like never before. It is amazing to me how powerful simple blood clotting factors are. I started to really learn how to strengthen my own blood by eating more nutritious meals, staying hydrated, and even avoiding alcohol.

Recognizing and Analyzing Cues

Nurses should maintain a level of clinical judgment when treating patients at risk for thrombocytopenia, such as those with an underlying hematologic disorder, liver disease, or recent use of medication associated with platelet depletion. It is vitally important to work closely with all members of the health-care team, but particularly hematologists, to provide timely diagnoses and interventions and ongoing management. A careful physical exam from head to toe may reveal cues that point to decreased platelet count and possibly thrombocytopenia. These cues include bruising, purpura, petechiae, excessive bleeding from minor cuts or injuries, bleeding from gums, hematomas, hematuria, heavy menstrual bleeding, frequent or spontaneous nosebleeds, and blood blisters in the mouth or on the body. Other cues to analyze are downward trends in platelet counts and vital sign deviations such as tachycardia, hypotension, and, in severe cases, hypoxia. A past medical and social history may reveal recent exposure to heparin or heavy alcohol use, which may cause thrombocytopenia.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

When deciding on hypotheses and solutions, nurses should always prioritize a patient's airway, breathing, and circulation. Because thrombocytopenia is a circulation problem, it is important to perform a comprehensive physical exam, paying attention to potential clinical manifestations. The nurse should consider the potential causes of thrombocytopenia, including immune-mediated causes, decreased production of platelets from bone marrow or nutritional disorders, or medications such as heparin or other anticoagulants.

Taking action includes the nursing interventions of administering prescribed medications, coordinating blood transfusions and products as ordered, providing patient education on bleeding and injury prevention, and

collaborating with the health-care team. Actions to reduce further bleeding include avoiding sharp objects and using an electric razor or a soft toothbrush to avoid tissue integrity issues. Safety implications include identifying patients at high risk of falling and educating patients to avoid contact sports. Dietary and nutrition interventions include avoiding alcohol (which decreases platelet production) and avoiding foods that may disrupt the intestinal lining. In the event the patient sustains a fall or trauma, imaging, such as a head CT scan, may be clinically warranted to rule out bleeding in the brain.

Thrombocytopenic conditions that have been acutely stabilized also require thorough education. Patients should be taught the pathophysiology of the disease and the importance of adhering to the treatment plan and identifying signs and symptoms of acute bleeding and hemorrhage. As demonstrated during the COVID-19 pandemic, vaccinations for COVID-19 and influenza can decrease or even eliminate risk for exacerbation of forms of ITP that have been caused by viral illness (ITP Support Association, n.d.).

Evaluation of Nursing Care for the Patient with Thrombocytopenia

Evaluation of interventions for thrombocytopenia requires an ongoing and methodological process to assess their efficacy and assess any changes that implemented measures have on the patient's hemostasis levels. The nurse should keep the following points foremost in mind:

- The primary focus of evaluation is to monitor the patient's platelet counts to detect improvements or declining trends.
- It is also important to evaluate the patient's response to medications. The nurse should be aware of side effects and adverse reactions to prescribed medications, which may include nausea, vomiting, and clot formation.
- Documentation is essential to visualize trends in vital signs, blood components, and clotting times. Indications that the patient is improving include normalization of vital signs and blood tests showing stabilizing or improving platelet levels and decreasing clotting times.

Medical Therapies and Related Care

Medical treatments for thrombocytopenia depend on its cause, severity, symptoms, or complications associated with its presence. Treatment plans are individualized, requiring close collaboration among health-care providers and ongoing monitoring to assess treatment efficacy and make necessary adjustments. Patients should be taught to recognize signs of bleeding and to prioritize follow-up care.

HIT presents serious clinical challenges, so prompt recognition, appropriate management strategies, and collaboration among health-care providers are critical in mitigating its associated complications. HIT can be managed effectively by immediately stopping all forms of heparin therapy and other anticoagulant agents like direct thrombin inhibitors (e.g., argatroban, bivalirudin, fondaparinux) to avoid further thrombosis. Warfarin typically should be avoided during the acute stage of the condition due to the risk of skin necrosis. Other essential components of care for managing HIT effectively include monitoring platelet counts regularly and conducting ongoing assessment for potential complications. The removal, treatment, and return or replacement of blood and blood products, known as **plasmapheresis**, may be performed help remove antibodies when treating HIT.

There are several interventions for ITP, including:

- corticosteroids, such as prednisone or dexamethasone, which are immunosuppressant medicines used to moderate immune system activity and help protect from immune-mediated thrombocytopenia. They are the first-line treatment for ITP.
- immunosuppressive therapy, which is given when the patient's immune system is attacking itself. It carries the risk of depleting the body's ability to fight pathogens naturally, but it can be a helpful treatment for ITP, when the immune system is hypersensitive and destroying its own platelets. Medications such as azathioprine, mycophenolate mofetil, cyclophosphamide, and rituximab can help decrease the autodigestion of valuable platelets.
- **intravenous immunoglobulin infusion therapy (IVIG)**, in which antibodies collected from multiple donors are administered intravenously over several days or weeks. IVIG treatment keeps immunity active but controlled, protecting affected tissues from further injury while the body fights infection by pathogens.
- removing the spleen, which can help decrease platelet destruction and increase platelet counts, increasing

their numbers significantly. This treatment should only be considered when chronic ITP does not respond to other therapies.
- thrombopoietin receptor agonists, which form a class of medications for chronic ITP. They work by stimulating the production of platelets from the bone marrow.

Regardless of the cause, platelet transfusions can be used to directly increase the body's platelets levels. This intervention is often used in cases such as severe bleeding or when platelet numbers have dropped dangerously low. Effective treatment is also contingent on addressing the actual cause of thrombocytopenia. If it is alcohol induced, for example, then, in addition to stabilizing platelets, alcohol cessation is key.

16.5 Neutropenia

LEARNING OBJECTIVES

By the end of this section, you will be able to:
- Discuss the pathophysiology, risk factors, and clinical manifestations associated with neutropenia
- Describe the diagnostics and laboratory values in neutropenia
- Apply nursing concepts and plan associated nursing care for the patient with neutropenia
- Evaluate the efficacy of nursing care for the patient with neutropenia
- Describe the medical therapies for neutropenia

A medical condition marked by abnormally low levels of neutrophils is called **neutropenia**. WBCs play an integral part in our immune system's defenses against pathogens. A **neutrophil** is a type of WBC that helps fight against bacteria and fungi. Neutrophils make up most of the WBC populations in the human body: normally, there are up to 8,000/µL of a whole-blood sample (Yale Medicine, n.d.). Someone with mild neutropenia has WBC levels of 1,000–1,500/µL; moderate neutropenia is characterized by WBC levels of 500–1,000/µL, and severe neutropenia by WBC levels below 500/µL (Yale Medicine, n.d.).

Consider the WBCs as the soldiers in the body's army against common pathogens like bacteria and fungi. When the body recognizes invading pathogens, it releases WBCs into the area to attack, engulf, and destroy them. A WBC count higher than 11,000/mm^3 demonstrates the body is fighting an infection, whereas a WBC below 4,000/mm^3 may mean there are no more WBCs left to fight, leaving the body without protection and at risk for a dangerous infection. Nursing assessment and medical treatments are then needed.

Pathophysiology of Neutropenia

There are many causes of neutropenia, including chemotherapy, which suppresses bone marrow production of neutrophils. Certain antibiotics and antiseizure medications can also decrease the number or effectiveness of neutrophils. Cancer, tumors, and conditions such as aplastic anemia and myelodysplastic syndromes can hinder the bone marrow's ability to produce neutrophils, and certain infections, such as HIV, can decrease neutrophil levels. Autoimmune disorders, such as lupus and rheumatoid arthritis, can mistakenly attack neutrophils, leading to neutropenia. Without adequate amounts of neutrophils, the body is at risk of further infections.

Types of Neutropenia

Classifying neutropenia assists health-care providers in understanding its cause, forecasting its progression, and deciding on appropriate interventions. The following types of neutropenia are defined based on their respective causes:

- Autoimmune neutropenia is when the immune system mistakenly attacks and destroys neutrophils, leading to low neutrophil counts.
- Chronic idiopathic neutropenia is characterized by persistently low neutrophil counts without apparent cause.
- Congenital neutropenia is present at birth and is generally due to a genetic mutation in the bone marrow, where blood cells are created.
- Cyclic neutropenia is a form of neutropenia in which individuals experience regular, cyclic fluctuations in their neutrophil counts; a complete cycle typically happens every 21 days.
- Drug-induced neutropenia is caused by certain chemotherapy drugs and antiseizure medications such as carbamazepine. Other drugs, such as certain antivirals, antibiotics, and antipsychotics also can have an impact.

- Infectious neutropenia is caused by the body's normal response to external pathogens.
- Post-transplant neutropenia is a side effect of immunosuppressive medications taken after organ or stem cell transplant.
- Secondary (acquired) neutropenia is caused by another condition such as a bacterial, fungal, or viral infection. Underlying conditions may be HIV, hepatitis, cancer, aplastic anemia, or autoimmune diseases.

Treatment and management strategies depend on identifying the specific type and addressing underlying causes whenever possible.

LINK TO LEARNING

The Immune Deficiency Foundation provides more information about the diagnosis and treatment of chronic neutropenia (https://openstax.org/r/77neutrop) on this website.

Clinical Manifestations

Symptoms include traditional characteristics of any infection, such as fever, fatigue, sore throat, swollen lymph nodes, ulcers in the mouth or anus, pain, swelling at an infection site, diarrhea, and dysuria if a bladder infection is present.

Diagnostics and Laboratory Values

A common test to identify the body's neutrophil level is a CBC count. Additional tests may include a bone marrow sample to identify cell growth and features. Identifying the cause of infection may require additional blood tests, as well as diagnostic radiography. A comprehensive physical exam and complete history can also help identify causes of infection or exposure that may have caused the neutrophil disorder. If there is high degree of suspicion for neoplastic (tumor related) causes, a bone marrow biopsy may be warranted.

Nursing Care of the Patient with Neutropenia

Patients with neutropenia require close nursing supervision to reduce infection risks and promote overall well-being. Close cooperation between all members of the health-care team and patient education are also integral parts of effective nursing interventions for neutropenia management (Yale Medicine, n.d.).

Recognizing and Analyzing Cues

By completing the normal nursing duties of obtaining a health history and completing a thorough physical exam, the nurse can optimize care for a patient with neutropenia. Subjective data may include fatigue, sore throat, pain, and urinary symptoms such as urgency and frequency. Objective data may reveal signs of infection such as fever, swollen lymph nodes, mouth ulcers, rash, and inflammation. Assessing nutritional status may help the nurse evaluate any nutritional deficiencies that may contribute to neutropenia. Diets that are deficient in folate and vitamin B_{12} may lead to neutropenia (Yale Medicine, n.d.). A CBC count will reveal low WBC levels.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Acute neutropenia requires hospitalization to avoid further risks of infection. To reduce infection transmission, patients are typically given their own room, a positive pressure isolation room if available, and placed on **reverse precautions**, also known as neutropenic precautions, which are measures to avoid introducing additional pathogens to the patient, such as:

- Fresh flowers are avoided to decrease exposure to chemicals or *Aspergillus* fungi infection.
- Fresh fruit and uncooked meats are avoided to avoid foodborne contaminants.
- Meticulous hand hygiene and upholding aseptic techniques all are directed at reducing nosocomial infection.
- Providers, staff, and visitors wear masks to protect the patient from opportunistic infections.
- Routine surveillance of temperature, monitoring absolute neutrophil counts, and thorough skin assessments are performed to help identify the source of an infection or signs of a potentially worsening infection.
- The nurse educates the patient to use good oral and pulmonary hygiene to avoid oral fungal infections and nosocomial pneumonia.

To optimize immune functioning, adequate hydration and protein in nutrition are instrumental. Administration of

antibiotics, antivirals, and corticosteroids may be necessary. Although neutropenia places patients at risk for bacterial infections, perpetual drops in WBC count and other aspects of immunity place patients at risk for **pancytopenia**, which is a reduction in platelets, RBCs, *and* WBCs.

Evaluation of Nursing Care for the Patient with Neutropenia

Evaluation of nursing interventions for neutropenia involves observing how patients react to care, monitoring for any indications of improvement, and making necessary modifications as required. For every nursing intervention, the nurse must evaluate the patient's response to the intervention for effectiveness as part of the nursing process (Yale Medicine, n.d.). Table 16.5 describes how common nursing interventions for neutropenia should be evaluated.

Nursing Intervention	Evaluation
Regularly monitor neutrophil count	Assess for trends and notify provider of progress or decline.
Assess signs and symptoms of infection	Assess for fever, infection, fatigue, and signs of inflammation.
Monitor vital signs	Evaluate stability of blood pressure and temperature. Document findings to recognize trends.
Observe skin and mucous membranes	Evaluate skin integrity and protect skin as needed to prevent breakdown. Assess for petechiae, ecchymosis, and pancytopenia.
Patient education	Instruct patient about the importance of adhering to medication orders and hand hygiene. Instruct patient how to practice hand hygiene. Address any barriers to understanding.
Neutropenic precautions: hand, oral, and respiratory hygiene	Evaluate staff and family adherence to neutropenic precautions and re-educate as needed. Provide needed supplies and signage.
Collaborate with health-care team	Evaluate team's ability to communicate and support the plan of care. Address any barriers to understanding.
Administer prescribed medications	Evaluate the patient's response to medications by monitoring the WBC count. Take precautions to avoid side effects or adverse reactions.

TABLE 16.5 Evaluating Common Interventions for Neutropenia

Medical Therapies and Related Care

Therapies should be focused on stimulating WBC creation to replace and recover healthy neutrophils. Classifying neutropenia helps health-care providers better comprehend its cause, predict its course, and tailor interventions accordingly. Treatment and management strategies entail identifying each specific type while targeting any possible root causes underlying it (Yale Medicine, n.d.). Regular blood count monitoring as well as cooperation among health-care providers are integral for successfully treating neutropenic conditions.

Antibiotic treatment can directly fight many bacterial and fungal pathogens. Corticosteroids can help suppress the body's immune response if the neutropenia is caused by an autoimmune condition that destroys the body's own WBCs. Medications to stimulate neutrophil genesis in bone marrow include filgrastim. Granulocyte colony-stimulating factor medications promote WBC production in the bone marrow. Antithymocyte globulin is an immunosuppressant that may be used to treat neutropenia from aplastic anemia. A bone marrow or stem cell

transplant may be performed if the underlying cause of neutropenia is a condition such as aplastic anemia or leukemia. Additionally, implementing reverse precautions can protect the patient from further infection during treatment.

16.6 Thrombotic Disorder

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss pathophysiology, risk factors, and clinical manifestations associated with thrombotic disorders
- Describe the diagnostics and laboratory values in thrombotic disorders
- Apply nursing concepts and plan associated nursing care for the patient with a thrombotic disorder
- Evaluate the efficacy of nursing care for the patient with a thrombotic disorder
- Describe the medical therapies for thrombotic disorders

A **thrombotic disorder** is a condition that interferes with hemostasis, which is the body's ability to clot or stop the flow of blood. A **thrombus** is a clot that forms inside a blood vessel. To effectively treat thrombotic disorders, nurses must understand the complex mechanisms of **coagulation**, which is the process of a liquid changing into a semi-solid or solid state. For blood, coagulation depends on **platelet aggregation**, which is the clumping together of platelets around RBCs (Figure 16.3). This process is supported by complex cascade of enzymatic reactions and essential proteins that combine to form a stable blood clot.

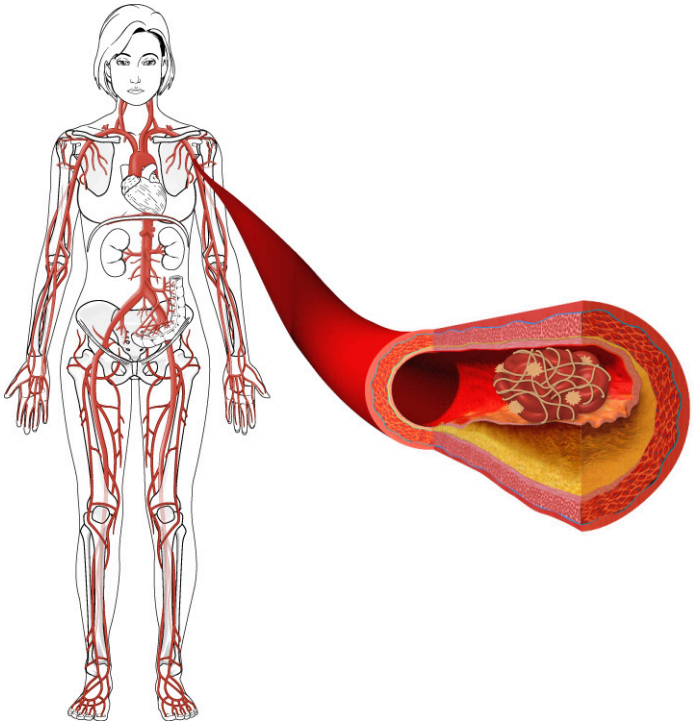

FIGURE 16.3 Platelets aggregate around, or bind to, red blood cells to form a clot within a blood vessel. (credit left: modification of work from Anatomy and Physiology, 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license; credit right: modification of "Blood Clot" by Blausen.com staff (2014) from "Medical Gallery of Blausen Medical 2014"/WikiJournal of Medicine, CC BY 3.0)

Pathophysiology of Thrombotic Disorders

Understanding the pathophysiology of thrombotic disorders is vital to an accurate diagnosis and successful management. There are three main types of clotting disorders: vascular, platelet, and coagulation.

Vascular disorders are conditions that may lead to bleeding. Examples include aneurysms and vasculitis, or inflammation of blood vessels; disruptions in blood flow due to blood vessel structure can also lead to vascular disorders. Constricted blood vessels can restrict the lumen of a vessel, provoking RBC aggregation and creation a blood clot.

Platelet disorders are caused by abnormalities in the quantity or quality of the platelets (Yale Medicine, n.d.).

Internal conditions of the bone, such as bone marrow cancer or tumors, can disrupt the normal production and quality of platelets. As previously discussed in 16.4 Thrombocytopenia, thrombocytopenia, or low quantities of platelets, can result in impaired clot formation. Irregular or abnormal qualities of platelets also disrupt normal coagulation.

Coagulation disorders stem from disruptions to the cascade of reactions that happens during clotting. Vitamin K deficiency is essential for clot formation; if not properly absorbed or deficient, clotting cannot occur. Because vitamin K is processed in the liver, people with liver disease may not be able to metabolize vitamin K and can be at increased risk for impaired clotting. An acquired disorder of coagulation is **disseminated intravascular coagulation (DIC)**, which triggers activation of the clotting cascade using up all the clotting factors, resulting in a mix of clotting and bleeding. Sepsis, trauma, and other diseases can trigger DIC.

Another pathology of coagulation disorders is due to fibrinolytic disorders. The breaking down of blood clots, or **fibrinolysis**, is needed to return the blood to homeostasis. Disorders in the ability to create a clot and then dissolve it are grouped in the pathology of fibrinolytic disorders.

Hereditary Thrombotic Disorders

Hereditary thrombotic disorders can often be detected when there is a family history of repeated venous thromboembolism. Genetic testing can confirm their presence and provide vital data for risk analysis as well as managing appropriate strategies such as anticoagulant treatment. It is crucial that individuals with family histories of blood clots seek appropriate medical care as soon as they experience repeated blood clots, so they can mitigate increased risks efficiently and avoid bleeding events. Two of the most common hereditary thrombotic disorders are factor V Leiden mutation and prothrombin G20210A mutation. Each occurs due to deficiencies in clotting factors from a genetic mutation in a particular gene (Stevens et al., 2018).

A **factor V Leiden mutation** is caused by a mutation in the *F5* gene, which prevents normal production of the factor V needed for clotting. The factor V Leiden mutation is one of the most frequently hereditary thrombotic disorders. The pathophysiology of *F5* gene mutation leads to the production of a factor V Leiden variant that resists inactivation by protein C, which is an anticoagulant protein. It acts as its own barrier against inactivation by anticoagulants such as warfarin. Individuals carrying a factor V Leiden mutation are more at risk of DVT and PE than people without this mutation.

A **prothrombin G20210A mutation** is a mutation that involves changes to the prothrombin (F2) gene, resulting in higher prothrombin levels, an essential clotting factor. High prothrombin levels contribute to blood clot formation by amplifying the coagulation cascade. Individuals carrying the prothrombin G20210A mutation have an increased risk of venous thromboembolism. Prothrombin G20210A carriers may also have an increased chance of DVT and PE, often in response to environmental influences like oral contraceptive use or pregnancy.

Venous Thromboembolism

In **deep vein thrombosis (DVT)**, a type of venous thromboembolism (VTE), a blood clot forms within a deep vein, most commonly in the leg or pelvis. This happens when blood clots form within the vessels of muscles as opposed to superficial veins of the skin. Pooling of the blood within the veins occurs, creating soreness, redness, and pain (Figure 16.4). Risk factors include immobility; surgery or trauma; certain medical conditions such as cancer, obesity, and inflammatory disorders; and other conditions that damage vessels. An unprovoked occurrence of DVT is typically linked to an inherited disorder. Genetic mutations involving factor V Leiden or prothrombin can increase the risk of incorrect clotting (Ginsberg et al., 2019).

FIGURE 16.4 With deep vein thrombosis, blood pools in the peripheral veins due to thrombosis. (credit: "Behçet's Syndrome and Thrombosis" by E. Seyahi & S. Yurdakul/National Library of Medicine, CC BY 2.0)

An untreated DVT may lead to serious health complications, including PE, and become a medical emergency. A clot that migrates from the deep veins and occludes the pulmonary arteries has a mortality risk of 25 percent (CDC, 2023).

A **pulmonary embolism (PE)** is a medical emergency caused when a blood clot from DVT migrates through the circulatory system and lodges itself within a pulmonary artery in a lung, blocking off oxygen and potentially leading to life-threatening consequences (Figure 16.5). Risk factors for PE include a previous history of PE or DVT, as well as immobility, prolonged bedrest after surgery, surgery itself, cancer, and chemotherapy; genetic mutations and medications that can cause blood clots are also risk factors for PE.

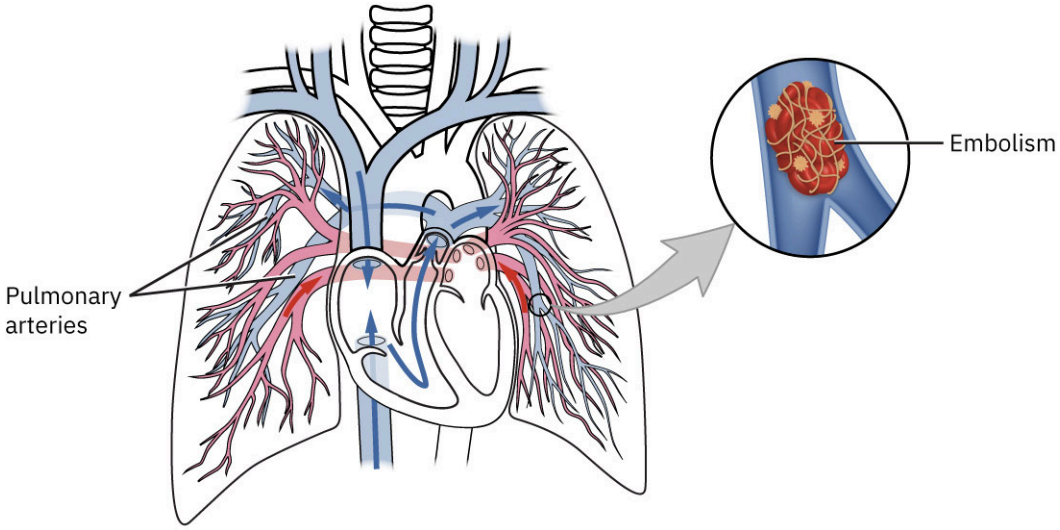

FIGURE 16.5 With a pulmonary embolism, a blood clot breaks free and travels through the circulatory system to the lungs, where it lodges in a pulmonary artery. (attribution: modification of work *from Anatomy and Physiology*, OpenStax, under CC BY 4.0 license)

Clinical Manifestations of VTE

Common symptoms of DVT include pain or tenderness of the leg or calf on the affected side, as well as swelling, edema, warmth, and redness. Complications can happen if the blood clot loosens and travels through the

bloodstream as an **embolism**. This can cause a pulmonary embolism in the lung, stroke if lodged in the brain or carotid arteries, or heart attack if lodged in the coronary artery.

The clinical presentation of a PE needs to be recognized quickly by a nurse because the prognosis is poor if oxygen is blocked within the lung and cannot perfuse into the main circulation. Symptoms include sudden shortness of breath, anxiety, chest pain that is sharper with inhalation, tachycardia, exertional dyspnea, cough with possible bloody sputum, sweating, dizziness, and disorientation (Ouellette, 2020). The complications from PE can be life-threatening because the clot blocks blood flow to the lungs, creating an increase in pulmonary artery pressure, which affects the right heart. Consequently, PE can exacerbate right-sided heart failure, leading to poor cardiac output and death.

Diagnostics and Laboratory Values of VTE

The most common diagnostic imaging tool for identifying DVT is ultrasound, which is noninvasive and allows providers to visualize the blood flow within a patient. A venous duplex is an ultrasound that examines for patency of veins in the legs. Coagulation laboratory studies can also look at the following factors relevant to clotting:

- **partial thromboplastic time (PTT)**: measures the intrinsic clotting cascade and the time it takes blood to clot. It is often used to measure the therapeutic effectiveness of heparin treatment. The normal range is 18–24 seconds.
- **prothrombin time (PT)**: uses extrinsic clotting factors to measure the time it takes for blood to clot. The normal range is generally 9–12 seconds.
- **international normalized ratio (INR)**: a standard measurement of PT that is used across different laboratories, because many laboratory values for PT and PTT may vary. The INR is also used to measure the therapeutic range of coagulation. The normal ratio is 1:2 (Favaloro, 2017).

Diagnosis of a PE should be quick for best patient outcomes. Imaging studies are helpful in visualizing the blood clot within the lungs. Computed tomography pulmonary angiography can visualize the pulmonary arteries within minutes to help expedite a diagnosis. Other laboratory work is slower but can include clotting factors, CBC count, PT, PTT, and INR. A laboratory test that has been done for decades but is now known to be less specific is the **D-dimer test**, which measures a protein in the blood created when a clot dissolves. A normal D-dimer result is considered less than 0.50 (Bounds & Kok, 2023). An elevated D-dimer result may indicate the presence of a blood clot or clotting disorder (Cleveland Clinic, n.d.). Current recommendations endorse using this test simply as a qualitative test when there is a low suspicion of PE (Bounds & Kok, 2023).

Nursing Care of the Patient with VTE

Treatment goals include managing the symptoms of existing clots and preventing further clot formation. Common interventions include administering anticoagulant medicines (blood thinners) to avoid additional clotting (Peck & Brown, 2020). Nursing interventions also include monitoring the patient's vital signs, assisting with airway and breathing, sitting the patient up in bed, and educating the patient about their condition.

Recognizing and Analyzing Cues

Nurses must remain diligent when it comes to monitoring patients for cues of excess blood clotting. To obtain cues, the nurse should complete a medical history, including any family history of clotting disorders, and examining risk factors—especially for those undergoing surgical procedures and for high-risk populations. Timely recognition of signs and symptoms along with collaboration among health-care providers allows prompt diagnosis and intervention in individuals at higher risks of blood clots. Education and preventive measures are also essential components of nursing care for these high-risk groups.

Completing a thorough physical exam can help the nurse identify cues such as warmth or redness in the lower legs or sudden respiratory problems that may be indicative of a DVT or PE. Laboratory work should be reviewed for clotting levels, including PT, PTT, and INR. Nurses should assess for changes in skin color and temperature, sudden chest pain worsened by deep breathing or movement, tachycardia, cough, hemoptysis, and laboratory studies (Anderson et al., 2021). One endorsed mnemonic to consider when assessing for the possible presence of DVT are the 6Ps: pulselessness, pallor, pain, perishingly cold, paresthesia (numbness), and paralysis. Capillary refill may be delayed by longer than 2 seconds. For recognizing PEs, a combination of subjective and objective complaints should be analyzed. The patient may appear pale, work harder to breathe at rest, appear anxious, or have a drop in their

oxygen saturation level during ambulation. Vital signs may demonstrate tachycardia and may or may not show hypoxia.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The priority of care in patients with VTE is maintenance of hemodynamic stability and oxygenation. Patients with DVT should maintain bed rest and avoid further ambulation; the latter may promote clot migration. The nurse should avoid massage or rubbing the affected extremity, and the patient should be instructed to abstain from this also. The nurse should also perform a neurovascular assessment (using the 6Ps) and monitor capillary refill every shift—more frequently if the patient underwent an interventional procedure to surgically break down the clot.

Patients with acute PE tend to have a higher degree of symptom burden in regard to airway and breathing. Supplemental oxygen and putting the head of the bed up to high Fowler's position (i.e., sitting up with spine straight) can assist with ventilation and oxygenation.

First-line therapies for acute VTE management include the initiation of blood thinners, either through the IV infusion of heparin or the administration of subcutaneous, low-molecular-weight heparins or direct oral anticoagulants (DOACs). Patients with a PE may require step-down or intensive care unit (ICU) level of care, with cardiac telemetry and frequent hemodynamic monitoring if there is a significant clot. Identification and treatment of atrial dysrhythmias put patients at risk for VTE occurrence.

Patients who have potential risks for thrombotic disorders should be educated about the risks of smoking while taking oral contraceptives or undergoing hormone replacement therapy, and should be discouraged from smoking while using oral contraceptive therapy. The vasoconstriction from nicotine in addition to the increased viscosity of blood from hormonal contraceptives may put a woman at risk for a pulmonary embolism or DVT. Patients with a hereditary thrombotic disorder may need to explore other methods of birth control to reduce risk of a thrombotic event. During assessment, nurses must interview patients to determine if there is any family history of thrombotic disorders. Patients with factor V Leiden will require lifelong anticoagulant therapy.

VTE prophylaxis is considered a standard of care in medical-surgical nursing. To decrease the risk of VTE occurrence, nurses may use a **sequential compression device (SCD)**, which uses sleeves that fit over a patient's legs and intermittently inflate and deflate to assist with blood mobilization in the legs (Figure 16.6). SCDs should never be used if the patient already has a DVT, because the pressure could dislodge the clot into circulation and increase the risk for PE, stroke, or heart attack. Prophylaxis also includes applying compression hose that help with venous return and decreasing edema. Early mobilization is also a part of the nursing care plan, along with frequent ambulation or with passive range of motion exercises. Adequate hydration and frequent mobilization also help prevent VTE occurrence. Nurses should also provide education on pharmacological therapies, which may be short term (e.g., 6 months) or longer.

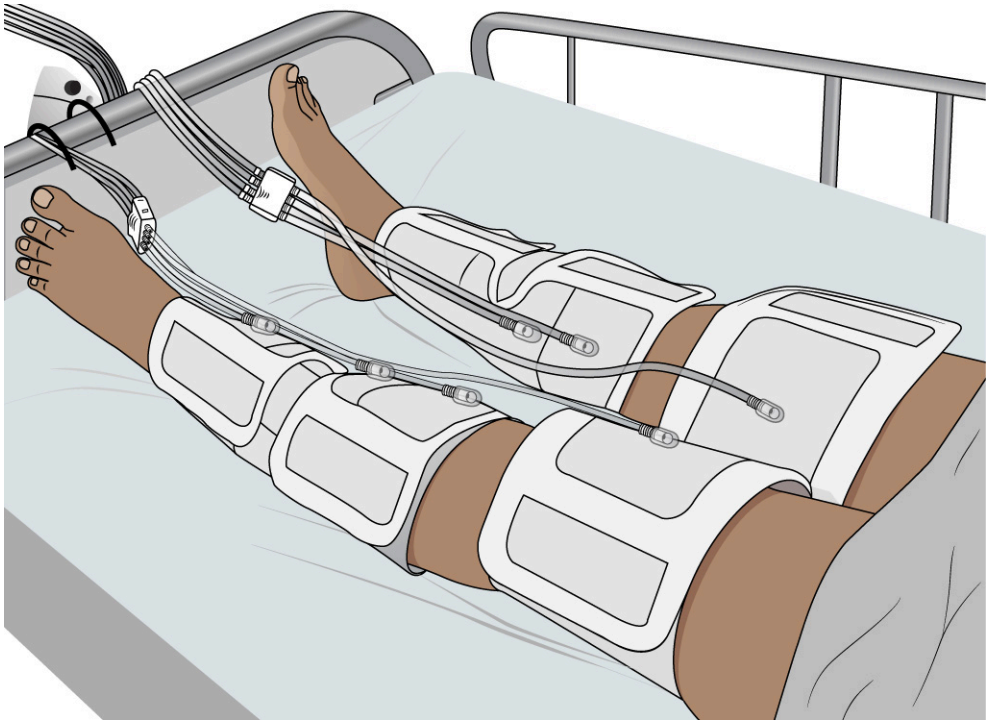

FIGURE 16.6 Sequential compression devices wrap around the patient's legs and intermittently inflate and deflate. This assists with mobilizing blood when the patient is bed-bound. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Evaluation of Nursing Care for the Patient with VTE

As part of the nursing process, reevaluation is an important step to identify how the plan of care should be modified, if needed, based on the patient's response to treatments and interventions. The nurse should evaluate the progress and patient response to nursing interventions for common problems seen in thrombotic disorders. Evaluating trends for impaired gas exchange, pain, impaired mobility, and risks of infection and bleeding can alert the nurse to take action.

Evaluating Outcomes

Evaluation of nursing care may depend on the acuity or chronicity of the VTE. Examples of improvement include

- Patient will report decreased shortness of breath and exhibit normalization of respiratory rate and oxygen saturation levels.
- The patient will identify risk factors that promote VTE occurrence, such as smoking and concurrent use of oral contraceptives or hormone replacement therapy.
- The patient will report decreased pain, swelling, warmth, and redness of the affected extremity.
- The patient will verbalize the importance of adherence to anticoagulation therapy.

Medical Therapies and Related Care

Treatment involves targeting the root cause of the thrombotic disorder, providing replacement clotting factors if applicable, or taking anticoagulant drugs as appropriate based on each disorder's individual presentation. The most frequently used anticoagulants include heparin, warfarin, and apixiban. For chronic management, the choice of medication should be made collaboratively with the patient to ensure compliance and ease of administration, as well as consideration of cost. Historically, warfarin was the common drug of choice; however, it requires frequent blood monitoring. Newer DOACs do not require surveillance with bloodwork, but they may be more expensive.

16.7 Blood Products and Transfusion Principles

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the physiology of the antigen response with blood types
- Identify examples of blood products
- Explain the legal and ethical implications of administering blood products
- Describe the pertinent nursing assessments included in the care of a patient receiving a blood transfusion

A **blood transfusion** is a medical procedure involving the transfer of blood or its components from one individual (donor) to another individual (recipient). Blood transfusions have been performed for centuries (Figure 16.7). The first recorded transfusion was attempted in 1628, shortly after an English physician discovered the process by which blood circulates through the body (AABB, n.d.). Unfortunately, many early blood transfusions failed; practitioners were not aware of the differences of blood types. Once scientists identified the ABO system of blood types, in the early 20th century, transfusions became much safer because providers could ensure that patients receive only compatible blood.

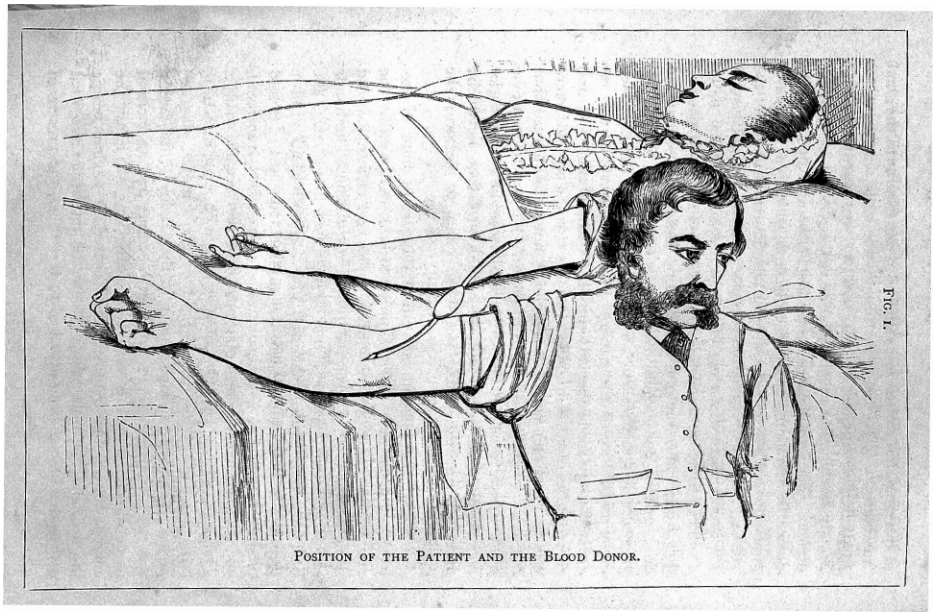

FIGURE 16.7 This illustration from a 19th-century English medical journal shows a man giving blood to a sick woman via a direct transfusion. (credit: "Immediate transfusion in" by J. H. Aveling/Wellcome Images, CC BY 4.0)

Blood transfusion protocols must adhere to stringent specifications to guarantee patient safety, including compatibility testing, proper storage, observance of expiration dates, and close supervision during administration. Transfusions may be administered based on clinical indications as well as tailored to a patient's unique medical conditions. Advances in blood component separation and processing techniques continue to enhance both the safety and efficacy of these processes.

Blood Typing and Antigen Response

ABO blood typing is a laboratory procedure used to ascertain an individual's blood type based on the different antigens (proteins) on the surface of the RBCs. The **ABO system** classifies these antigens into four main blood types: A, B, AB, and O. This test is essential in blood transfusion procedures to ensure compatibility between donor's and recipient's blood types. Blood typing is critical because if incompatible blood is given, the immune system treats the donor cells as if they were foreign invaders and attacks them accordingly. Mismatching of blood products has profound physiological effects if not done so correctly; a catastrophic effect of a severe immune response could have dire consequences, even death.

Table 16.6 lists the types of blood products that are compatible with each blood type (Poh et.al., 2021). Note that recipients with type AB blood can receive blood from any donors, and donors with type O blood can give blood to recipients of any blood type.

Blood Product	Recipient Blood Type	Donor Blood Type	Rh Compatibility
Red blood cells	A B AB O	A, O B, O AB, A, B, O O	Rh-negative patients must receive Rh-negative RBCs. Rh-positive patients must receive Rh-positive RBCs.
Plasma	A B AB O	A, O B, O AB, A, B, O O	Not applicable
Platelets	The same blood type is preferable but not necessary.		Rh compatibility is preferable but not necessary.
Cryoprecipitate (clotting proteins)	The same blood type is preferable but not necessary.		Not applicable

TABLE 16.6 Blood Products by Type

Examples of Blood Products

Recall that blood is composed of fluid (plasma, which contains clotting factors, electrolytes, and nutrients) and the three major formed elements (RBCs, WBCs, and platelets). These components can be separated and given as treatment for specific medical deficiencies. Table 16.7 outlines the major blood products for each component (American Red Cross, 2021).

Blood Product	Component	Indications	Storage
Packed red blood cells	RBCs, some plasma, and platelets as whole blood	For anemia resulting from blood loss, surgery, trauma, or medical conditions such as sickle cell disease	Typically stored refrigerated; have a shelf life of ~42 days
Fresh frozen plasma (FFP)	Plasma that contains clotting factors, proteins, and electrolytes	Corrects coagulation deficiencies, such as those caused by liver disease, massive transfusions, or clotting factor deficiencies	Frozen within 8 hours of collection and typically stored for up to 1 year
Platelets	Concentrated platelets with less plasma	For conditions with low platelet counts, such as leukemia, chemotherapy-induced thrombocytopenia, or platelet function disorders	Stored at room temperature with a shorter shelf life compared with other blood products (up to 5 days)
Cryoprecipitate	Derived from FFP; contains high concentrations of clotting factors, including fibrinogen	To treat bleeding disorders, particularly those related to fibrinogen deficiencies, such as in cases of trauma, surgery, or liver disease	Frozen within 8 hours of collection and typically stored for up to 1 year

TABLE 16.7 Blood Products and Components

Blood Product	Component	Indications	Storage
Albumin	Albumin, which is a protein-rich component of plasma	Used to treat hypovolemia, burns, or conditions for which plasma volume expansion is required	Stored at room temperature; has a longer shelf life compared with other blood products; provided in a glass bottle
Granulocyte transfusions	Granulocytes, which are a type of WBC	For severe infections or neutropenia in which the patient is not responding to antibiotics	Have a short shelf life; typically administered shortly after collection

TABLE 16.7 Blood Products and Components

Nurses need to understand the rationale for administering each blood product and the rationale for type and crossmatch. Transfusion reactions must be avoided, so donated blood must be compatible with the blood of the patient who is receiving the transfusion (Andiç, 2022). More specifically, the donated RBCs must lack the same ABO and Rh D antigens that the patient's RBCs lack (Andiç, 2022). For example, a patient with blood group B can receive blood from a donor with blood group B, because they lack the A antigen, or they can receive from blood group O because donors with blood group O lack all ABO blood group antigens (Andiç, 2022). Proper blood administration protocols must be followed exactly to avoid the devastating aftermath of mismatch transfusions.

If a patient has a low platelet level but is at risk for fluid volume overload, administering a smaller volume of 50 mL of cryoprecipitate is better than administering a full unit of whole blood (which is approximately 240 milliliters). If a patient's blood pressure, Hb, and Hct values are low and the laboratory values of platelets are within the normal range, then the volume of whole blood is the better choice. If the Hb, Hct, and vital signs are stable and a provider orders a unit of blood for transfusion, the nurse may need to call the provider and clarify the order.

READ THE ELECTRONIC HEALTH RECORD

Laboratory Values after PRBCs

The nurse is caring for a patient who reports feeling weak and tired all the time. The patient has a history of right-sided congestive heart failure, atrial fibrillation, and anemia. The nurse notes atrial fibrillation on the telemetry monitor. The provider ordered two units of PRBCs, each unit to be infused over 4 hours. Laboratory values show the following:

Laboratory Values	Normal Range	Result
Hct	37–52	↓ Hct: 22.4%
Hb	12–18	↓ Hgb: 6.9 g/dL
Blood urea nitrogen	4–10	↑ 21 mg/dL
WBCs	5–10	↑ 10,000/μL
Platelets	150–400	300,000/μL
Creatinine	0.6–1.2	↑ 1.8 mg/dL

TABLE 16.8 EHR

Laboratory Values	Normal Range	Result
Potassium	3.5–5.0	3.7 mEq/L
Sodium	135–145	137 mEq/L

TABLE 16.8 EHR

1. What information on the electronic health record concerns you?
2. Are any of these findings expected?
3. Is there any information you should question?

Legal and Ethical Implications

Nurses should be aware of the following legal and ethical considerations regarding blood transfusion. These considerations ensure the standards of care are followed and care takes place safely, responsibly, and with due regard for individuals' rights and well-being.

- Informed consent: Prior to administering blood transfusion services, health-care providers must obtain informed consent from either the patient or the patient's legal representative. Informed consent ensures that patients understand all potential risks, benefits, and alternatives associated with any procedure or health-care service offered to them. Respect for patients' autonomy and right to make informed health-care decisions are vital elements of ethical standards of care. Health-care providers must communicate clearly and transparently, providing accurate information for patients to make educated decisions based on facts (INS, 2024). The role of the nurse is to advocate for the patient and witness the consent, ensuring the information was provided in a manner the patient fully understands before the consent form is signed.
- Testing and screening: Blood donors must undergo stringent screening and testing protocols to guarantee safe blood donation practices. Legal regulations govern testing procedures to safeguard transfusion patients against infectious disease transmission through transfusions. Assuring blood product safety also reflects the ethical obligation to shield patients from potential harm. Rigorous testing is essential to safeguarding the health-care system and limiting disease transmission.
- Blood donation policies: Legal frameworks dictate who can donate blood and under what conditions. These regulations may include age and health requirements as well as restrictions based on recent travel or high-risk behaviors. From an ethical perspective, blood donation policies attempt to strike an appropriate balance between meeting an adequate blood supply while protecting donor and recipient well-being. Fairness in donation policies is vitally important in upholding public trust.
- Privacy and confidentiality: Information related to blood transfusions is protected under privacy legislation, offering legal certainty regarding data handling practices. Health-care providers must abide by stringent confidentiality standards. Respecting patient privacy is an ethical imperative and helps develop trust between health-care providers and patients. Protecting sensitive health information is critical for maintaining individuals' dignity and confidentiality. Legal frameworks may recognize religious or cultural exemptions to certain medical procedures, including transfusions. Health-care providers must navigate these exemptions while upholding patient safety.
- Reporting adverse events or complications: This may be legally mandated, but there are ethical considerations as well. Transparent reporting of adverse events creates an atmosphere of accountability and learning that makes possible continuous improvement of blood transfusion practices to protect patient safety and mitigate risks.
- Resource allocation: A network of local, state, and national guidelines regulates the dispersal of blood products. Ethical considerations begin with the limited supply of blood products. How should providers determine who receives a product if the demand exceeds the supply? How much should products cost, and what role, if any, should cost play in determining whose needs are met?

CULTURAL CONTEXT

Cultural and Religious Beliefs Regarding Transfusions

Ethical nurses consider the cultural diversity and religious beliefs of their patients when providing health care. Some religious groups do not accept blood transfusions. For example, Jehovah's Witnesses believe the Bible prohibits consumption of blood (Pavlikova & van Dijk, 2022). From their perspective, most believe receiving a blood transfusion, even in life-threatening cases, would violate this prohibition (Pavlikova & van Dijk, 2022). Providers must be prepared to offer alternative interventions that do not use blood products. For example, a bolus normal saline fluid may be used to maintain blood pressure, and the hormone epoetin may help stimulate natural bone marrow production of RBCs.

Nursing Care of the Patient Receiving Blood Products

Though an everyday nursing procedure, administering blood transfusions requires close monitoring to ensure patient safety and well-being. The following are key nursing interventions for blood transfusions:

- Patient assessment: Assess the patient's baseline vital signs such as temperature, heart rate, blood pressure, and respiratory rate before starting the transfusion process. This information will enable you to quickly notice any deviations that indicate a potential reaction to the transfusion. Document any signs or symptoms of anemia or other conditions necessitating transfusion. The nurse ensures all appropriate informed consent forms are comprehensively completed by the patient or their legal representative prior to the transfusion procedure. The nurse should also educate the patient and their caregivers about the blood transfusion processes, including the purpose, risks, and benefits, to ensure an optimal experience during the blood transfusion.
- Blood product verification: Institutional policies require two registered nurses to implement the verification. The nurses should confirm the patient demographics, medical record number, signed consent form, the blood product type, the registered number that is applied to the product, and the product expiration time and date.
- IV access: Establish IV access and ensure patency before retrieving the blood product. The specialized filtered tubing made for blood products is called Y tubing. It allows a unit of the blood product to be hung on one side of the tubing and normal saline to be on the second side of the Y. Typical IV gauges used for routine or nonurgent transfusions are 20–22 gauge for adults, whereas 16–18 gauge or central venous catheters are preferred for rapid administration (Lotterman & Sharma, 2023). Access assessment is critical because blood products must be administered within a certain time once arriving on the patient's floor.
- Patient monitoring: Before, during, and after the transfusion, the patient should be monitored carefully. Assessments typically occur within the first 15 minutes after the transfusion, then hourly and at the completion of the transfusion (Lotterman & Sharma, 2023). Delivery of the blood differs between patients, depending on the perfusion requirements and how well the patient can handle volumes. Patients with a history of heart failure may require a slower transfusion due to an impaired heart ventricle that cannot tolerate fast infusions. In contrast, patients with active hemorrhage may receive blood products more rapidly, as prescribed.

REAL RN STORIES

Nurse: Nancy, BSN
Years in Practice: Forty-five
Clinical Setting: Surgical step-down unit
Geographic Location: Washington, DC

I have been a nurse for a long time! I remember giving blood in the 1980s before HIV was identified. Before the blood-transmitted virus was identified, our blood transfusion delivery was much less strict. The testing and safety measures for any unit of donated blood were less stringent. It has been interesting to watch the evolution of a much more detailed process for blood donations and administration. Although it takes the nurse much longer to prepare

and administer a single unit of PRBCs, it is satisfying to know the blood we are giving a recipient has been strictly screened for a myriad of potential problems. Blood is life, but giving the wrong blood can be death!

Recognizing and Analyzing Cues

The most critical cues for a nurse to be aware of during a transfusion is for a transfusion reaction within the first 15 minutes of transfusion (Bates & Owusu-Ofori, 2020). Table 16.9 lists important cues by body systems.

System	Cues
Neurologic	Dizziness, anxiety, localized pain Disorientation if the reaction develops into shock
Integumentary	Flushing, itching, hives, chills Edema if the reaction is due to fluid volume overload
Respiratory	Wheezing, shortness of breath, dyspnea
Cardiac	Tachycardia, hypotension, shock
Gastrointestinal	Nausea, abdominal pain
Genitourinary	Dark or blood-tinged urine, hematuria, lower back pain
Renal	Hematuria, hemoglobinuria

TABLE 16.9 Most Common Transfusion Reaction Cues by Body System

There are different types of reactions to a blood transfusion. Treatment varies depending on the cause (Cleveland Clinic, n.d.).

- A **febrile nonhemolytic reaction**: This is the most prevalent reaction type. It usually manifests through an increase of 1° in temperature over baseline. When this happens, patients typically receive acetaminophen for treatment before returning for further transfusion if deemed safe by their medical provider.
- An **allergic reaction**: This happens when there is an allergy to one or more proteins present in donor blood. Symptoms may range from mild irritation to serious anaphylaxis (which is rare). Most often, this reaction will not require disrupting transfusion, because diphenhydramine may provide sufficient relief.
- An **acute hemolytic reaction**: This reaction, typically due to an administrative mistake, is caused by an ABO mismatch between donor and recipient. The patient may complain of low back pain, itching, or increased body temperature. It can lead to serious symptoms, including low blood pressure and shock, hemoglobinuria, nausea, vomiting, pain, chills, and fever. The patient can show extreme distress, including hypotension from shock as well as nausea, vomiting, chills, fever, and **hemoglobinuria** (the breakdown of Hb in the urine).
- A **delayed hemolytic reaction**: Most transfusion reactions happen within 15 minutes of transfusion. If the reaction happens after 15 minutes, it is considered delayed. Delayed hemolytic reactions manifest with similar clinical symptoms as other transfusions.
- A **septic reaction**: Septic reactions arise when blood products, particularly platelets, are improperly stored and become contaminated. Shortly after the transfusion, patients may exhibit signs of severe infection, including high fever, chills, hypotension, and tachycardia, as well as nausea, vomiting, dyspnea, and even cardiovascular collapse. Septic transactions usually happen within hours or soon after blood transfusion has taken place.
- A **transfusion-related acute lung injury (TRALI)**: Transfusion reactions can often result in acute respiratory distress syndrome due to an immune response between donor antibodies and antigens in a recipient, which triggers mediator release, resulting in pulmonary edema and causing rapid tissue swelling. Signs and symptoms manifest during or shortly after transfusion; they include respiratory distress symptoms such as shortness of breath. On physical assessment, the patient may have rales in the lung fields.

- A **transfusion-associated circulatory overload (TACO)**: This reaction happens when fluid volumes exceed expectations. Symptoms include shortness of breath and coarse lung sounds. This condition could also include possible widespread edema. Patients with background heart failure may receive a dose of diuretics, such as furosemide, to mitigate this reaction.

LINK TO LEARNING

A further explanation of the differences between TACO and TRALI (https://openstax.org/r/77TACOTRALI) is given in this video.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

When administering a blood transfusion, nurses use clinical judgment and critical thinking to identify a transfusion reaction. Prioritizing actions is critical to avoid serious complications. For example, knowing the patient's baseline vital signs and clinical status are key to be able to compare baseline values with any changes throughout the transfusion. Immediately stopping the blood transfusion when a reaction is occurring is important. Knowing the steps to take to stop a transfusion reaction helps the nurse generate solutions and act quickly:

- Stop the transfusion.
- Disconnect the blood tubing and flush the patient's IV with normal saline.
- Prime new IV tubing with normal saline and infuse at a lowered rate to keep the vein open (typically 20 mL/h).
- Notify the provider.
- Monitor the patient's vital signs and remain with the patient.
- Prepare to obtain blood and urine specimens from the patient to send to the laboratory.
- Send the used blood bag and IV tubing to the blood bank for further testing.

Evaluation of Nursing Care for the Patient Receiving Blood Products

Evaluating nursing care for patients receiving blood products is essential to ensure both safety and effectiveness during a transfusion. Evaluation involves gauging a patient's response to the transfusion, observing for any possible complications, and quickly responding to any issues as soon as they arise. The following are key questions to ask during evaluation:

- Did the patient's vital signs remain stable during administration of blood products? Did they normalize after the transfusion?
- Did the patient's blood Hb, Hct, platelets, and RBC levels return to target norms?
- Does the patient report improvement in fatigue?
- Did the patient tolerate the blood transfusion without any incidence of transfusion reaction?

By conducting systematic nursing care evaluations before, during, and after blood transfusions, nurses can identify any problems, respond quickly to complications that arise, and promote patient safety and well-being. Continuous quality improvement efforts further optimize this process and the patient outcome.

Summary

16.1 Anemias

- Anemia is a deficiency of red blood cells (RBCs) or hemoglobin (Hb). It impairs the blood's oxygen-carrying capacity. Clinical signs and symptoms of anemia include fatigue, weakness, pale skin, and shortness of breath. Pathophysiology of anemia includes nutritional deficiencies, chronic diseases, genetic factors, and chronic bleeding.
- Diagnostics and laboratory values include a variety of blood tests and a physical examination to identify manifestations of the disorder and diagnose the cause. The main diagnostic is a hemogram, a detailed analysis of a blood sample that examines not only the quantity of RBCs, WBCs, and platelets but also their size and color and the percentage of iron in them.
- Nursing care for patients with anemia involves regular monitoring of vital signs and review of hematology laboratory tests. Management of symptoms includes helping the patient conserve energy effectively. Medication administration includes nutritional supplements and erythropoietin as ordered. Blood products may also be administered when necessary. Patient education is provided on diet, lifestyle modifications, and adherence to medications. Nurses also provide emotional support by providing resources and acknowledging the patient's fatigue.
- To evaluate the effectiveness of nursing interventions, the desired goal must first be identified and then compared with the outcomes. The following are a few examples of outcomes the nurse would evaluate for a patient with anemia: assessing vital signs to determine if ranges are met, assessing the patient for continued syncope or altered consciousness, and identifying if there has been an improvement in overall symptoms.
- The medical therapies that apply to the care of the patient with anemia include medication administration, such as iron supplements. In severe cases, blood transfusions may be necessary.

16.2 Hereditary Disorders

- Pathology of hematological disorders includes genetics, and hereditary disorders such as sickle cell anemia (SCA) and thalassemia are common in ethnic and racial groups, such as the those of African, Mediterranean, Middle Eastern, or South Asian descent (sickle cell anemia) or Mediterranean, Asian, or African descent (thalassemia).
- Identification of these disorders includes specific diagnostic testing, such as bone marrow aspiration, complete blood cell (CBC) count, total bilirubin test, genetic testing, hemoglobin solubility test, hemoglobin electrophoresis, peripheral blood smear, and reticulocyte count.
- Nursing care is directed if the patient is experiencing an acute exacerbation or through prevention. Acute interventions include hydration, pain control, or, if required, transfusion. Chronic management may be medications, iron chelation therapy, or bone marrow transplantation.
- The efficacy of nursing care is measured by symptom control during an exacerbation, normalization of laboratory test results toward target goals (clinically driven), and prevention of complications.
- Medical treatments for patients with hereditary hematological disorders include medication administration, blood transfusions, and iron chelation therapy.
- Emphasize infection prevention measures like vaccinations and proper hygiene, given the greater susceptibility to infection associated with some hematologic disorders.

16.3 Polycythemia

- Polycythemia is an abnormal increase in the number of red blood cells in the bloodstream.
- The two types of polycythemias are primary polycythemia (polycythemia vera), which is caused by a gene mutation, and secondary polycythemia, which is caused by an external factor triggering an increase in EPO production.
- Clinical manifestations include headache, dizziness, fatigue, pruritus, and jaundice.
- Diagnosis is based on CBC count, genetic testing, and, in some cases, bone marrow biopsy.
- Treatment includes therapeutic phlebotomy, myelosuppressive medications, aspirin, anticoagulants, and JAK2 inhibitors.
- Lifestyle measures include smoking cessation, adequate hydration, and regular exercise and nutrition to support normal RBC production.

- Nursing actions include medication administration, patient education, identification of complications, collaborative care, and monitoring of laboratory tests.

16.4 Thrombocytopenia

- Thrombocytopenia is a hematologic disorder with the hallmark feature of decreased platelet count, which increases the risk of bleeding.
- The causes of thrombocytopenia include immune-mediated destruction, decreased platelet production, and increased consumption of platelets.
- Nursing actions for patients with thrombocytopenia include frequent monitoring of vital signs and assessing any signs of bleeding. Monitoring laboratory results of platelet counts is crucial to awareness of trends of improvement or decline.
- Patient education must include bleeding precautions, such as using a soft toothbrush, and injury prevention. Patients must be taught to notify their provider of any increase in bleeding.
- Medical treatments include corticosteroids and immunosuppressive drugs for immune-related thrombocytopenia. Intravenous immunoglobulin (IVIG) and thrombopoietin receptor agonists stimulate platelet production. Splenectomy is a last resort for chronic ITP resistant to other treatments. Platelet transfusions can be given to immediately increase platelet counts in the acute care setting. Plasmapheresis may be used to remove antibodies in HIT.

16.5 Neutropenia

- Neutropenia refers to abnormally low levels of neutrophils, a type of white blood cell that is critical to fighting bacterial and fungal infections.
- Neutropenia can be caused by chemotherapy, radiation, certain medications, bone marrow disorders, infections, autoimmune diseases, and congenital genetic mutations.
- Nursing interventions include infection prevention, assessment, and monitoring; patient education; and management of neutropenic precautions.
- Medical treatments for neutropenia include antibiotics targeting the offending pathogen, adjustment of medications that may be causing neutropenia, bone marrow stimulants, granulocyte colony-stimulating factor, bone marrow or stem cell transplantation, monitoring of laboratory test results, and overall infection control.

16.6 Thrombotic Disorder

- Two common thrombotic disorders are deep vein thrombosis (DVT) and pulmonary embolism (PE).
- A thrombotic disorder creates a blockage in a blood vessel, threatening adequate oxygen delivery to tissues.
- The pathology of thrombotic disorders includes hypoxemia and tissue hypoxia.
- Classic symptoms of DVT include redness and warmth of the affected limb, as well as pain or tenderness.
- Classic key symptoms of a PE include tachypnea, redness of sputum, difficulty breathing, especially on exertion, disorientation, and anxiety due to lack of oxygen to the brain.
- Nursing actions include completing a thorough medical history and physical exam, stabilizing breathing, notifying the provider of changes, monitoring vital signs, preparing the patient for diagnostic studies, and administering anticoagulant medications as ordered.
- Medical treatment is focused on identification of the thrombus and use of anticoagulants.

16.7 Blood Products and Transfusion Principles

- Blood typing is a necessary safety procedure because the antigen response differs among blood types.
- Examples of blood products include PRBCs, plasma, FFP, cryoprecipitate, and proteins, such as albumin, which can each be given separately depending on the patient's specific need.
- A type and crossmatch of blood ensures the recipient of a blood donation receives the correct ABO match and as well as the least possible risk of adverse reactions.
- There could be cultural considerations that spill into the ethical and legal protections when administering blood products. Informed processes are in place to respect these.
- Nursing assessments of the patient's tolerance of administered blood products are required before, during, and after administration and are critical to ensure the safe administration of blood.
- Blood transfusion reactions can be caused by improper handling and storage of blood products,

incompatibility, contamination, and fluid overload.
- Safe transfusion is a priority in patient care.

Key Terms

ABO system categorization of blood into four main types—A, B, AB, and O—based on the different antigens on the surface of red blood cells

acute hemolytic reaction transfusion reaction due to an ABO mismatch, which can lead to serious signs and symptoms, including low blood pressure and shock, hemoglobinuria, nausea, vomiting, pain, chills, and fever

alcoholic thrombocytopenia condition in which excessive alcohol consumption results in decreased platelet count in the blood, leading to decreased clotting mechanisms and increasing the risk for bleeding and bruising

allergic reaction transfusion reaction due to an allergy to one or more proteins present in donor blood; symptoms may range from mild irritation to serious anaphylaxis

anemia medical condition characterized by deficient production of red blood cells or of hemoglobin

blood transfusion medical procedure involving the transfer of blood or its components from one individual (donor) to another individual (recipient)

bone marrow aspiration test to verify the presence of sickle cell anemia by measuring the production of red blood cells in the bone marrow

coagulation process of a liquid (e.g., blood) changing into a semi-solid or solid condition

complete blood count (CBC) measurement of the number of red blood cells, white blood cells, and platelets in a sample of blood

D-dimer test test that measures a protein in the blood produced after the breakdown of blood clots

dactylitis hand-foot syndrome manifesting as swelling (edema) and pain of the hands and feet during a sickle cell crisis

deep vein thrombosis (DVT) medical condition marked by the formation of blood clots within deep veins in the legs

delayed hemolytic reaction transfusion reaction that happens more than 15 minutes after transfusion, with similar symptoms to other types of reactions

disseminated intravascular coagulation (DIC) acquired disorder that activates the clotting cascade, using up all the clotting factors and resulting in a mix of clotting and bleeding

embolism blood clot that has come loose and can travel through the body

erythropoiesis hemoglobin production

erythropoietin (EPO) hormone made in the kidneys that stimulates bone marrow to produce red blood cells

factor V Leiden mutation disorder caused by a mutation to the *F5* gene, which prevents normal production of the factor V needed for clotting

febrile nonhemolytic reaction most prevalent type of transfusion reaction, usually manifesting as an increase of 1° in temperature over baseline

fibrinolysis breaking down of blood clots after they form

folate-deficiency anemia type of anemia in which inadequate levels of the vitamin folate within the body cause low levels of red blood cells and hemoglobin; also called megaloblastic anemia

hematopoietic system body structures responsible for the formation of blood cells

hemoglobin (Hb) protein in red blood cells that is key to the transport of oxygen from the lungs to cells and tissues

hemoglobin electrophoresis test to diagnose sickle cell anemia by distinguishing different forms of hemoglobin to detect the form and characteristics of sickle-shaped red blood cells

hemoglobin solubility test quick screening method to detect sickle hemoglobin by mixing blood with a reducing agent to inactivate hemoglobin and form characteristic crystals

hemoglobinuria breakdown of hemoglobin in the urine

hemogram detailed analysis of a blood sample that examines not only the quantity of red blood cells, white blood cells, and platelets but also their size, color, and percentage of iron

hemolysis destruction of red blood cells

hemostasis physiological process that prevents and controls bleeding

heparin-induced thrombocytopenia (HIT) immune-mediated side effect caused by prolonged use of anticoagulants like heparin

idiopathic thrombocytopenic purpura (ITP) autoimmune condition marked by an abrupt and significant drop in

platelet count, leading to increased risks of bleeding and anemia; more frequently referred to as immune thrombocytopenia

international normalized ratio (INR) standard measurement of prothrombin time that is used across different laboratories

intravenous immunoglobulin infusion therapy (IVIG) intravenous administration of antibodies collected from multiple donors to maintain a controlled immune response that fights infection without further injuring tissues damaged by idiopathic thrombocytopenic purpura

intrinsic factor essential protein needed for the absorption of vitamin B_{12} by the small intestine

iron chelation therapy therapy in which medications bind to excess iron in the bloodstream, creating a compound that can then be expelled from the body through excretion

iron-deficiency anemia anemia due to inadequate levels of iron

jaundice yellowing of the skin and sclera

mean corpuscular hemoglobin concentration (MCHC) concentration of hemoglobin in a red blood cell

mean corpuscular volume (MCV) average size of red blood cells in a sample

neutropenia medical condition marked by abnormally low levels of neutrophils

neutrophil type of white blood cell that helps fight against bacteria and fungi

pancytopenia reduction in platelets, red blood cells, and white blood cells

partial thromboplastic time (PTT) measurement of the time it takes blood to clot, based on the intrinsic clotting cascade

peripheral blood smear test enabling analysis of red blood cell shape and condition for diagnostic purposes

pernicious anemia anemia due to inadequate levels of vitamin B_{12}; also referred to as vitamin B_{12} malabsorption anemia

plasmapheresis removal, treatment, and return or exchange of blood and blood products

platelet aggregation clumping together of platelets in the blood

polycythemia hematologic condition marked by an abnormal increase in the number of red blood cells

polycythemia vera type of polycythemia that originates from the bone marrow and is caused by a genetic mutation; also called primary polycythemia

prothrombin G20210A mutation disorder caused by a mutation to the prothrombin (*F2*) gene, which results in higher levels of the clotting factor prothrombin

prothrombin time (PT) measurement of the time it takes for blood to clot, based on extrinsic clotting factors

pulmonary embolism (PE) blood clot from deep vein thrombosis that migrates through the circulatory system and lodges within a pulmonary artery in a lung, blocking off oxygen

purpura large, discolored, purple areas that may be seen throughout the body, due to internal bleeding

reticulocyte count measures the number of young RBCs in a blood sample

reverse precautions measures to avoid introducing additional pathogens to the patient

secondary polycythemia type of polycythemia caused when erythropoietin stimulation occurs as an adaptive reaction to other conditions

septic reaction transfusion reaction resulting from blood products that have been incorrectly stored and thus become contaminated

sequential compression device (SCD) external sleeves that wrap around a patient's legs and inflate and deflate to promote blood flow

sickle cell anemia (SCA) one of the many types of sickle cell diseases that causes severe anemia

sickle cell disease inherited blood disorder caused by abnormal hemoglobin production that forms red blood cells into crescent-shaped "sickles"

thalassemia group of hereditary blood disorders that affect the hemoglobin genes, leading to decreased erythropoiesis

therapeutic phlebotomy removal of excess red blood cells by reducing overall blood volume

thrombocytopenia hematologic condition characterized by decreased platelets in the bloodstream, significantly impairing the blood's ability to clot effectively; also called low platelet count syndrome

thrombopoietin protein released by the liver

thrombotic disorder condition that interferes with hemostasis, or blood clotting

thrombus clot that forms inside a blood vessel

total bilirubin test blood test that measures the amount of bilirubin in a patient's system, indicating liver strain

from the accelerated turnover of RBC cells caused by sickle cell anemia

transfusion-associated circulatory overload (TACO) transfusion reaction that happens when fluid volumes have exceeded expectations; symptoms include shortness of breath, coarse lung sounds, and possible edema formation

transfusion-related acute lung injury (TRALI) transfusion reaction manifesting as acute respiratory distress syndrome due to an immune response between donor antibodies and antigens in a recipient

vaso-occlusive crisis result of sickle cell anemia caused by constricted blood vessels and hypoxemia; also known as a pain crisis and sickle cell crisis

Assessments

Review Questions

1. What is the primary function of RBCs in humans?
   a. to carry oxygen directly to tissues
   b. to fight off infections
   c. to form clots
   d. to regulate blood pressure

2. As a nurse caring for a patient with a past surgical history of a gastric bypass, which type of anemia would the nurse anticipate the patient to be most at risk for?
   a. pernicious anemia
   b. iron-deficiency anemia
   c. hemolytic anemia
   d. folate-deficiency anemia

3. A 45-year-old female presents to the emergency room and is diagnosed with moderate anemia. What would you expect the patient's Hb level to be?
   a. 12.5 g/dL
   b. 11.7 g/dL
   c. 13.2 g/dL
   d. 9.1 g/dL

4. What clinical finding in your patient with anemia would lead you to believe that the treatment plan was working?
   a. The patient's blood pressure dropped from 116/76 mm Hg to 96/62 mm Hg during the shift.
   b. The patient's Hb increased from 8.6 g/dL to 9.9 g/dL over 8 hours.
   c. The patient is maintaining an oxygen saturation of 90% with oxygen supplementation through a 2-L nasal cannula.
   d. The patient has a delayed capillary refill.

5. What is a characteristic feature of sickle cell disease?
   a. microcytic RBCs
   b. macrocytic RBCs
   c. crescent-shaped RBCs
   d. normocytic RBCs

6. What is the primary cause of pain crises in individuals with sickle cell disease?
   a. bacterial pneumonia infection
   b. RBCs blocking blood flow to tissues
   c. increased bleeding
   d. increased bilirubin levels in the body

7. In sickle cell disease, what complication can arise due to the destruction of RBCs and release of excess bilirubin?

a. hematuria
b. splenomegaly
c. jaundice
d. thrombocytopenia

8. The nurse is caring for a patient with thalassemia who receives frequent blood transfusions. What potential complications of these transfusions should the nurse watch for? (Select all that apply.)
a. iron overload
b. hypoxia
c. hemolysis
d. thrombocytopenia
e. neutropenia

9. What is the primary feature of polycythemia?
a. elevated WBC count
b. increased platelet count
c. elevated Hb and Hct levels
d. decreased RBC count

10. In secondary polycythemia, what is a pathophysiology that causes increased RBC production?
a. decreased EPO levels
b. chronic hypoxia
c. genetic mutation
d. excess energy

11. What are appropriate nursing interventions for managing polycythemia? (Select all that apply.)
a. administering anticoagulants
b. initiating therapeutic phlebotomy
c. encouraging smoking cessation
d. administering antibiotics

12. What laboratory result would indicate thrombocytopenia?
a. increased RBC count
b. decreased platelet count
c. decreased RBC count
d. decreased plasma level

13. How do corticosteroids help to treat thrombocytopenia?
a. They directly increase platelet production in the bone marrow.
b. They inhibit immune-mediated platelet destruction.
c. They decrease clotting factors III, IV, and VIII.
d. They decrease destruction of platelets in the spleen.

14. What organ can cause platelet destruction that results in ITP?
a. liver
b. kidneys
c. spleen
d. bone marrow

15. What type of medication should the nurse expect to administer to a patient with neutropenia?
a. anticoagulant medications
b. nonsteroidal anti-inflammatory drugs
c. bone marrow stimulant

d. antacids

16. What nursing intervention is appropriate for a neutropenic patient?
a. encouraging a diet high in fresh fruits
b. administering antivirals
c. advising the patient to take very large doses of vitamin C
d. educating the patient on hand, oral, and respiratory hygiene practices

17. A patient was admitted to the emergency room with a fever and swollen lymph nodes. What additional cue would lead you to suspect that the patient has neutropenia?
a. The patient was recently diagnosed with and is being treated for candidiasis.
b. The patient recently fractured their toe.
c. The patient is a smoker.
d. The patient ran a marathon 48 hours ago.

18. What condition is a contributory risk factor for the development of DVT?
a. hypernatremia
b. prolonged immobility
c. vitamin C deficiency
d. hypothyroidism

19. What laboratory test is commonly used to assess for PE?
a. venous duplex
b. computed tomography pulmonary angiography
c. PT
d. CBC count

20. What medication(s) would the nurse anticipate for treatment of a DVT? (Select all that apply.)
a. warfarin
b. aspirin
c. low molecular-weight heparin
d. clopidogrel
e. apixiban

21. If a patient has type A blood, what type(s) of blood can the patient receive? (Select all that apply.)
a. A
b. B
c. AB
d. O

22. The nurse finds that a patient has developed a rash and lower back pain 15 minutes after receiving a blood transfusion of cryoprecipitate. What is the nurse's priority action?
a. Stop the infusion.
b. Hang 1,000 milliliters of normal saline at 100 mL/h.
c. Call the provider.
d. Send the blood bag and tubing to the laboratory.

23. The nurse started the transfusion of one unit of PRBCs. What clinical finding(s) indicate a transfusion reaction? (Select all that apply.)
a. lower back pain
b. same blood pressure as before the transfusion
c. urticaria
d. pruritus

e. wheezing

24. A trauma patient comes into the emergency room with signs of hemorrhage. Vital signs are as follows: heart rate, 130; blood pressure, 84/62 mm Hg; respiratory rate, 24 per minute; oxygen saturation, 92%. Given this clinical assessment, what IV access device should the nurse start?
   a. 18 gauge
   b. 22 gauge
   c. 20 gauge
   d. central line

25. What blood type can be donated to anyone?
   a. O
   b. AB
   c. A
   d. B

Check Your Understanding Questions

1. Identify a condition that may be complicated due to anemia, and explain why.

2. You are the nurse working with a dietitian to create a high-iron diet for your patient with iron-deficiency anemia. Describe a meal that would be a good source of iron for the patient. Explain your reasoning.

3. What nursing intervention could you suggest for someone experiencing pernicious anemia? Explain your answer.

4. What dietary supplements may be needed for patients with thalassemia?

5. Explain the difference between primary and secondary polycythemia.

6. Identify causes of secondary polycythemia.

7. A patient follows up at their annual hematology visit for polycythemia. How would the nurse evaluate that the patient is not having any complications?

8. What medical therapies would the nurse anticipate for polycythemia?

9. Identify several appropriate nursing interventions for a patient with thrombocytopenia.

10. A nurse is caring for a patient who drinks alcohol daily and has been receiving heparin. Explain how these behaviors put the patient at risk of thrombocytopenia.

11. Describe the approach used when deciding which treatment to use for patients with neutropenia.

12. Describe how you would evaluate that nursing care is effective for a patient with neutropenia.

13. Identify several assessment findings that are indicative of a PE.

14. Identify several appropriate nursing interventions for people at risk for thrombotic disorders.

15. Explain why a patient who smokes and also takes oral contraceptives is at a higher risk for VTE.

Reflection Questions

1. As a nurse, what are some key challenges associated with caring for patients with anemia? What nursing actions can help to overcome these challenges?

2. You are caring for a patient with thalassemia who has high iron levels due to frequent blood transfusions. The patient is confused about the recommended iron chelation therapy. Explain in your own words what it is and how it helps.

What Should the Nurse Do?

1. Your 16-year-old patient was recently diagnosed with SCA after experiencing a vaso-occlusive crisis. What are some ways you can evaluate how well the patient understands signs and symptoms to report to their provider?
2. You are a nurse on a medical-surgical unit caring for a patient diagnosed with polycythemia vera. You have recently witnessed sudden pain, swelling, and discoloration to their left lower leg. After conducting an assessment, you suspect there might be a deep vein thrombosis present, causing the leg symptoms. What should you do?
3. An off-duty nurse at a family function observes a loved one, known to have thrombocytopenia, sustain a fall with head trauma and a forehead laceration. What should the nurse do?
4. Describe three ways a nurse would assess the efficacy of nursing care for a patient with alcohol-induced thrombocytopenia.
5. You are the nurse caring for a patient on neutropenic precautions. You have heard from other staff nurses that a family member named Mark, who visits daily, does not follow the neutropenic precautions, and you are concerned. Today, you notice Mark is bringing several other friends into the patient's room. What should you do?
6. The nurse is caring for J.T., a 34-year-old male, trauma patient who was in a motor vehicle accident two days ago. He is now stabilized in the ICU. He has already received 4 units of PRBCs over the past 3 days. His Hb value today is 14.2 g/dL, Hct is 48%, and blood pressure is 122/80 mm Hg. The doctor has ordered another unit of PRBCs. What should the nurse do?

Competency-Based Assessments

1. Develop a teaching aid to give your patient as a supplement to VTE prevention education.

CHAPTER 17

Nervous System and Chronic Diseases of the Nervous System

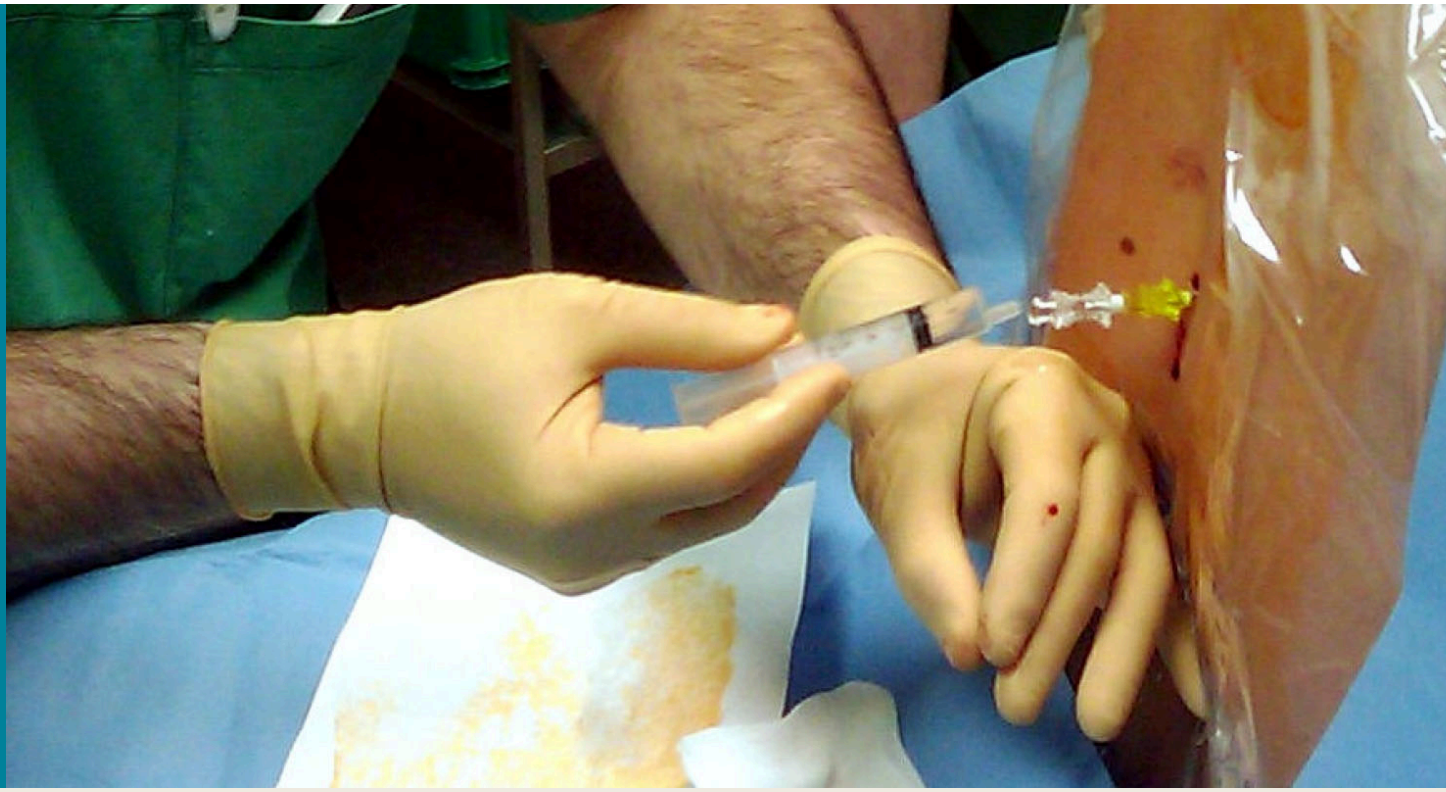

FIGURE 17.1 The structure and function of the human nervous system begins in the brain and spinal cord. The image shows a lumbar puncture, a procedure used to identify infections in the cerebral spinal fluid. (credit: modification of work from *Anatomy and Physiology 2e.* attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

CHAPTER OUTLINE

INTRODUCTION The body's communication and response systems are comprised of trillions of neurons, and billions of these are within the brain. When these neurons function properly, they route signals to the brain, enabling the brain and nervous system to support the body's performance, including activities such as breathing, walking, and reading this textbook.

Sometimes, neurons are injured, which may negatively affect the brain's ability to function. This chapter discusses disorders and diseases that injure neurons and explores how this affects the brain and the body. For patients who experience any of these conditions, nurses provide essential services as caregivers and advocates. If patients must

learn to live with their disease or condition, nurses provide them with information and support to help them make this adjustment. Regardless of the patient's disease or condition, nurses should keep in mind that they must always collaborate and communicate effectively with the patient's health-care team. This may include physicians, neurologists, surgeons, therapists, dieticians, pharmacists, and other health-care professionals. As appropriate, nurses should work with these team members and use interdisciplinary approaches to develop a comprehensive health-care treatment plan. Working with the health-care team, nurses should monitor each patient and address changes in the patient's care plan as needed.

17.1 Intracranial Pressure Changes

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the Monro-Kellie doctrine
- Discuss the pathophysiology, risk factors, and clinical manifestations for intracranial pressure changes
- Describe the diagnostics and laboratory values in the disease of intracranial pressure changes
- Apply nursing concepts and plan associated nursing care for the patient with intracranial pressure changes
- Evaluate the efficacy of nursing care for the patient with intracranial pressure changes
- Describe the medical therapies that apply to the care of intracranial pressure changes

To stay healthy and function optimally, the brain must have stable **intracranial pressure (ICP)**, which refers to the pressure within the rigid confines of a skull. In the skull, brain tissue, blood, and **cerebral spinal fluid (CSF)**—a colorless fluid found within the subarachnoid space of the meninges of the brain, which surrounds both brain and spinal cord, acting to maintain health and functioning of the brain—exist together. Proper regulation of ICP is vital to achieve an ideal **cerebral perfusion pressure (CPP)**, which is the net pressure gradient required to ensure sufficient oxygen delivery to the brain and allow optimal pressure levels for proper brain health.

This first part of this section covers the Monro-Kellie doctrine, which helps explain why maintaining ICP is so critical. The section discusses the pathophysiology, risk factors, and clinical manifestations for intracranial pressure changes and describes the expected diagnostics and laboratory values for the disease of intracranial pressure changes. The remainder of the section describes nursing concepts and explains the role of nurses in caring for patients who experience intracranial pressure changes as well as techniques and therapies that enable nurses to provide the best possible care to these patients.

Monro-Kellie Doctrine

The **Monro-Kellie doctrine** is an important concept in neurology and neurosurgery that establishes relationships among brain, blood, and CSF volumes within the rigid confinement of a skull (Figure 17.2). Scottish doctors Alexander Monro, George Kellie, and John Hughlings Jackson independently contributed to the doctrine's development between 1795 and 1810. The doctrine's basic principle recognizes that craniums are closed and nonexpandable structures that house the brain, blood, and CSF. Because skulls have rigid constraints, intracranial volume remains constant. As such, if the volume of the brain, blood, or CSF increases or decreases, this change in volume must be counterbalanced by a corresponding change in the volume of one or both of the other components inside the skull. Nurses must apply the concepts of this doctrine to understand and treat conditions that affect ICP, such as traumatic brain injuries, tumors, cerebral edema, and hemorrhages.

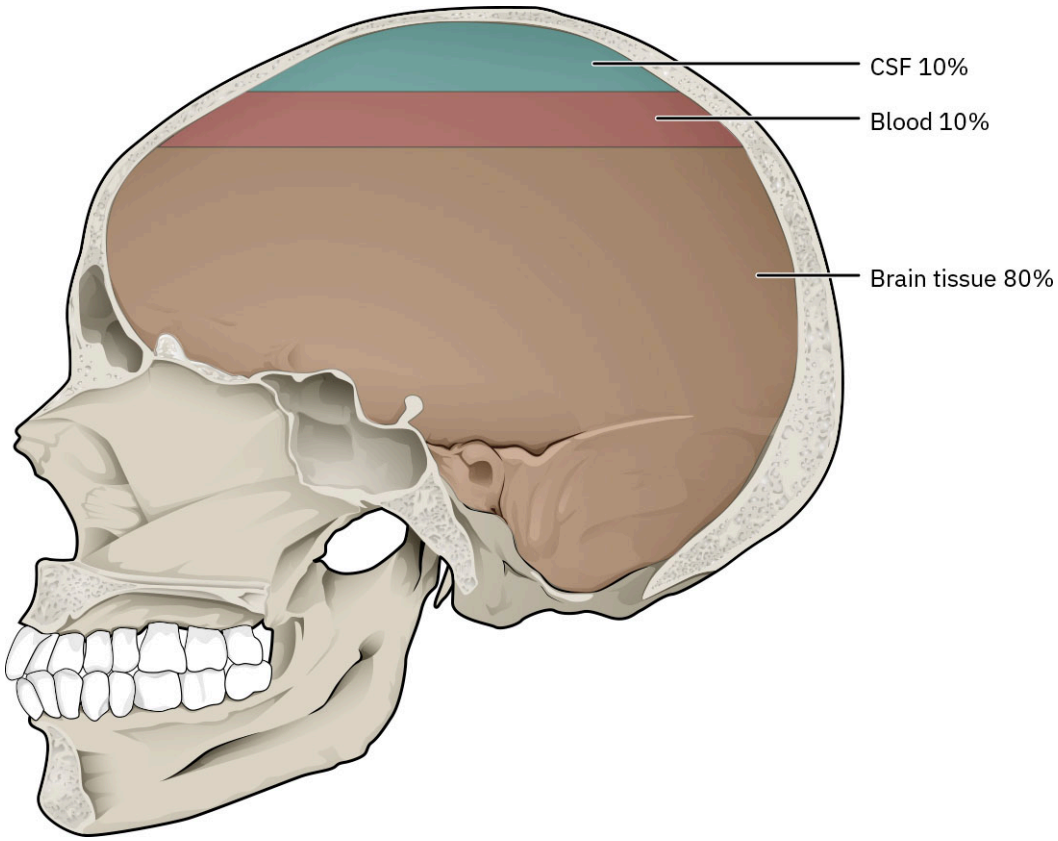

FIGURE 17.2 The Monro-Kellie doctrine states that the skull is a fixed space and any change within the brain tissue, blood, or cerebral spinal fluid (CSF) will force the others to compensate. Increased ICP

ICP is determined by measuring the pressure exerted by fluids in the brain, such as CSF. Typically, ICP levels are measured in millimeters of mercury (mm Hg). While a patient is in a prone position, normal ICP should be between 7 and 15 mm Hg. When a patient is upright, this measurement should not be more than 15 mm Hg (Munakomi & Das, 2024).

ICP can be affected by many factors, including changes to blood volume, changes in the rates of CSF production and absorption, fluctuations in brain tissue volume, and obstruction of CSF flow. When **increased intracranial pressure (IICP)** occurs, it can cause compression of brain tissues and blood vessels, making it a serious condition with the potential to damage the brain.

Pathophysiology of Increased ICP

Common causes for IICP include head trauma, brain tumors, bleeding within the brain (intracerebral hemorrhage), vascular disorders such as aneurysms, and conditions such as infections that cause brain swelling. When any of these occur in the brain, they cause displacements of brain tissue, blood, and/or CSF, and may lead to IICP.

Clinical Manifestations of IICP

The clinical manifestations of IICP may include headaches, nausea, vomiting, altered mental status and level of consciousness (LOC), seizures with sensory and motor function impairments, and changes to speech patterns. Patients may also have visual disturbances, such as impaired eye movement, pupillary changes, and swelling in the optic disks known as **papilledema**.

Some patients with IICP may experience abnormal body posturing, including the following: **decerebrate posturing**, which is a neurological reflex movement of muscles causing the limbs to extend and hold rigidly at the sides of the body; **decorticate posturing**, which is a neurological reflex movement of muscles causing the limbs to flex and hold rigidly across the chest; and **flaccid posturing**, which occurs when muscles lack tension and go limp. IICP may also cause changes in a patient's vital signs that result in **Cushing's triad**, which is a combination of widened pulse

pressure (or larger distance between diastolic and systolic measurements) in the blood pressure, bradycardia (low pulse rate), and irregular breathing patterns. In infants, IICP may cause issues such as bulging fontanels, cranial suture separation, increased head circumference, and a high-pitched cry.

Assessment and Diagnosis of IICP

To assess IICP, health-care professionals, including nurses, should obtain the patient's medical history and do a physical examination that assesses the patient's mental alertness, orientation, reflexes, bodily movements and functions, pupils and eyes, and overall behavior. This process may include using the Glasgow Coma Scale (GCS) to assess a patient's consciousness level, evaluating the patient's motor response, eye openings, and verbal responses. Patients with a GCS score lower than 8 should be monitored for IICP (Munakomi & Das, 2024).

LINK TO LEARNING

The Glasgow Coma Scale (GCS) (https://openstax.org/r/77GlasgowComa) can be a vital tool to assess a patient's level of consciousness. The GCS has been used by health-care professionals since 1974 and is recognized as an accurate, reliable resource.

Diagnostics and Laboratory Values

The diagnostic tools generally used for IICP include computed tomography (CT) scans, magnetic resonance imaging (MRI), and lumbar punctures. CT scans or MRIs may show structural abnormalities, tumors, hemorrhages, or other conditions that change the volumes of a patient's brain, blood, or CSF, causing IICP. Also useful is **cerebral angiography**, a type of x-ray that creates digital images of the anatomy of the brain with a focus on the blood vessels within and around the brain. Cerebral angiography identifies blockages and other abnormalities in the blood vessels of a patient's head and neck that may be causing IICP. CSF analysis, which examines the actual contents of CSF, including pathogens, may help determine the cause of IICP.

LINK TO LEARNING

CSF can help determine the cause of IICP testing (https://openstax.org/r/77CSFTesting) by evaluating the concentrations and levels of cells and various substances in CSF.

ICP monitoring with vital signs is also necessary. Monitoring devices include intraventricular catheters and parenchymal monitors. Intraventricular catheters are inserted through a hole in the skull and put in place to measure the skull's internal pressure as well as drain excess CSF (Figure 17.3). Parenchymal monitors are placed inside brain tissue to monitor pressure. In other words, intraventricular catheters and parenchymal monitors may reveal abnormal pressure readings. Pressures greater than 20 mm Hg require treatment (Munakomi & Das, 2024).

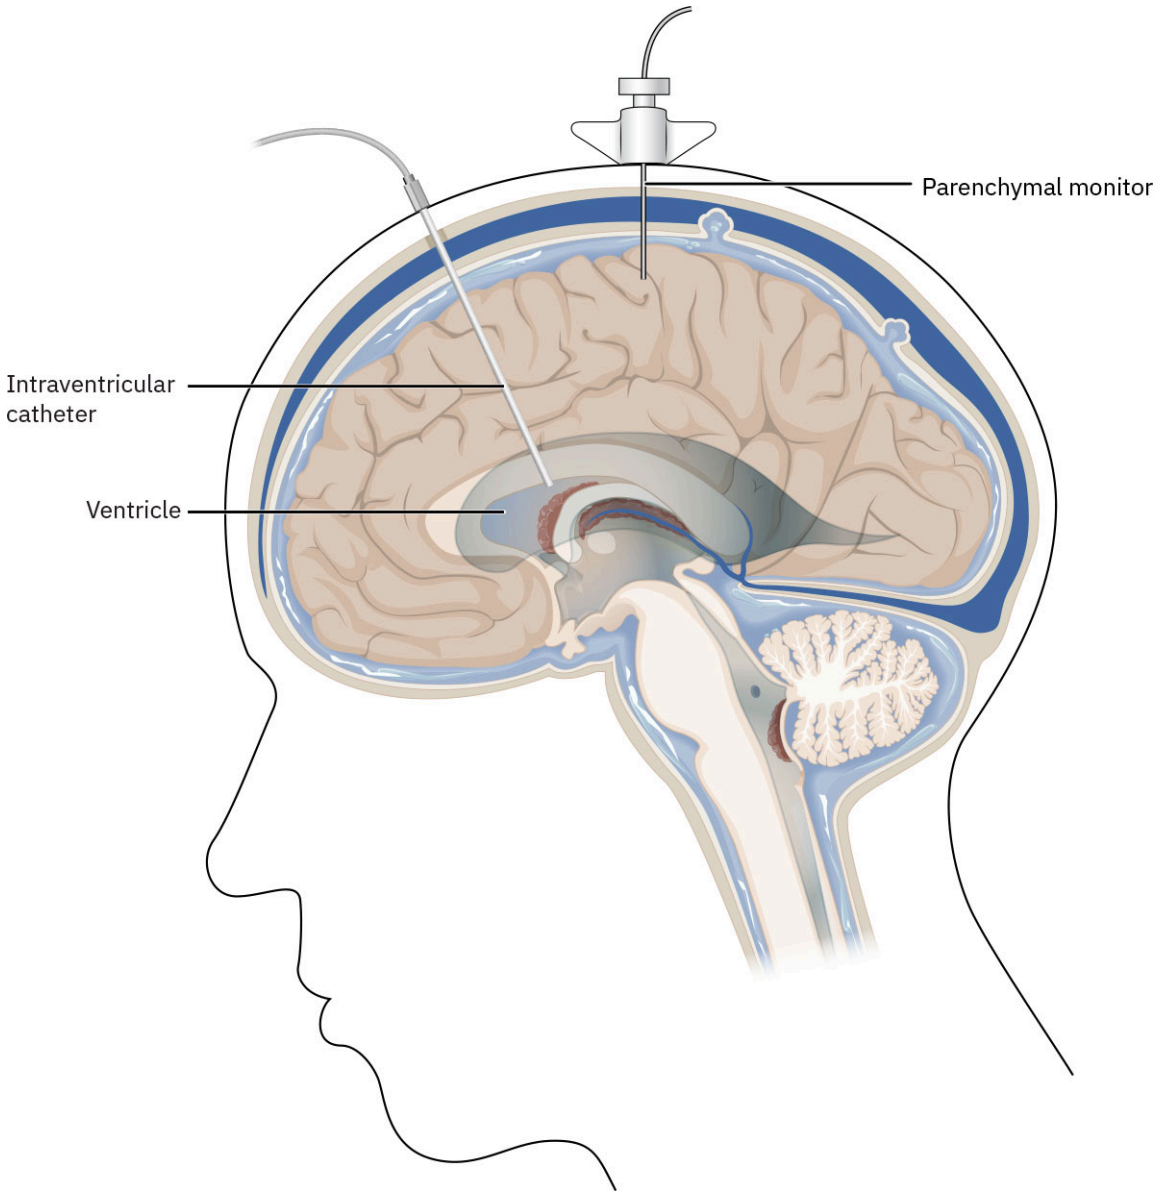

FIGURE 17.3 Intraventricular catheters can be useful tools for ICP monitoring. The catheter should be inserted into the skull via a small hole. Once the catheter is in place, it can be used to measure the skull's internal pressure. LIFE-STAGE CONTEXT

Age-Related Changes in Intracranial Pressure

Consider age-related changes in ICP from the very young to older adults when assessing neurological status. For example, in pediatric patients, an important consideration is fontanelle assessment. In infants, the fontanelles are soft and can even be visually bulging when the infant is experiencing IICP or sunken with decreased ICP. Bulging fontanelles may be a sign of IICP from inflammation and infection caused by hydrocephalus or meningitis.

In older adults, as well as younger patients with decreased mental functioning, mental status may be more challenging to assess for changes in the patient with major neurocognitive disorder (MND) or Alzheimer disease. Sudden confusion or disorientation, however, is never a good sign and is cause for further investigation.

Communication of symptoms is difficult in both the very young, older adults, or those who have trouble communicating. Motor functions may be difficult to assess in an infant who does not yet walk, or in an immobile

older person. Verbalizing headache symptoms can be difficult in a nonverbal infant or a confused adult.

Nursing Care of the Patient with IICP

IICP is generally an acute clinical concern that needs immediate medical attention. To provide care for patients with IICP, nurses use a physical examination and patient's subjective statements to gather data from a patient's vital signs, neurological status, and response to interventions.

Recognizing Cues and Analyzing Cues

The cues that indicate IICP include confusion, high blood pressure, headache, slurred speech, muscle weakness, difficulty breathing, blurred vision, and vomiting. Using patient statements, as well as test results, nurses should analyze these cues to identify causes of or contributors to IICP. Test results may reveal an underlying condition such as an infection, head injuries, high blood pressure, tumors, aneurysm, and swelling in the brain. If the patient has an ICP monitoring device, the nurse should include data from this device as part of the process to determine if the patient's ICP is above normal.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

Prioritize according to severity for patients with IICP, including urgency of intervention and potential impact of ICP levels. For instance, sudden neurological changes or signs of **herniation**, which is a protrusion of tissue displacing the brain, may necessitate immediate medical intervention. As noted precedingly, the cues and signs may include changes to a patient's mental alertness, blood pressure, ability to breathe, vision, bodily functions, muscle weakness, and general behavior. Solutions generated should be aimed at decreasing ICP as well as decreasing the risk of further harm caused by the IICP.

As with all diseases and conditions, the process to generate solutions should include collaborating with the patient's health-care team members, including neurologists and neurosurgeons. Use interdisciplinary approaches and include health-care professionals such as physical therapists, respiratory therapists, and pharmacists to develop a comprehensive care plan that also anticipates potential complications related to IICP, such as seizures or declining neurological status. Act by implementing the nursing interventions described in Table 17.1.

Nursing Care	Rationale
Complete focused neurological assessments	Changes in LOC, pupillary response and shape, motor function, speech, and vital signs indicate health issues.
Monitor vital signs.	VS are controlled in the medulla oblongata/brain stem, and worsening changes can signal herniation in the brain from IICP.
Elevate head of bed (HOB) 30 degrees.	Elevation of HOB can help with venous drainage to decrease ICP. Keep the body in alignment to protect spinal cord.
Avoid Valsalva maneuvers; use stool softeners/laxatives to avoid bowel straining.	Avoiding or minimizing bowel straining, coughing, or bearing down will reduce the risk of increases in ICP.
Monitor and maintain fluid and electrolyte balance.	Disruptions in hydration could affect ICP.
Implement measures to prevent fever.	Fever can increase ICP and exacerbate IICP.
Administer analgesics and complementary pain relief measures.	Pain and stress can cause IICP.

TABLE 17.1 Nursing Interventions for Patients with IICP

Nursing Care	Rationale
Support oxygenation and ventilation.	Adequate oxygenation and ventilation helps maintain appropriate ICP.
Monitor intracranial pressure.	Changes in ICP readings may indicate improvement, as well as declining health that needs attention.
Implement seizure precautions.	IICP can cause seizures.

TABLE 17.1 Nursing Interventions for Patients with IICP

Evaluation of Nursing Care for the Patient with IICP

The desired outcome for patients with IICP is a lower level of ICP. To determine if the patient's ICP is lower, nurses should evaluate the ICP pressure levels and GCS results, as well as the results of the patient's lab tests, including data for glucose and white blood cell (WBC) levels.

Medical Therapies and Related Care for IICP

Once IICP is diagnosed, treatment for these patients should focus on the cause of IICP. For example, patients with brain swelling may need medications, such as diuretics and corticosteroids, which help reduce swelling. Patients with tumors or hematomas may need surgical interventions to remove lesions. If the patient's IICP is caused by CSF drainage problems, the patient may need a ventriculoperitoneal shunt, external ventricular drainage system, or lumbar drain to control CSF drainage. A ventriculoperitoneal shunt is a thin tube that is inserted into the brain's ventricles to drain excess CSF. With an external ventricular drainage system, the patient's head is positioned to allow intracerebral pressure and gravity to work together to drain CSF. A lumbar drain is a small tube that is placed in the lumbar spine, rather than the brain's ventricles, to drain excess CSF.

Patients who have IICP due to infection or metabolic disturbances may need medications, such as antibiotics or aspirin. To determine the appropriate therapy to meet the needs of each patient, nurses should have a thorough understanding of the patient's condition, including the cues that indicate IICP, and should collaborate with other members of the patient's health-care team.

Decreased Intracranial Pressure

Although not as common as IICP, some patients experience decreased ICP, or intracranial hypotension. As noted previously, normal ICP should be between 7 and 15 mm Hg when a patient is lying down (Munakomi & Das, 2024).

Pathophysiology

When pressure within the skull and brain drops below normal, decreased intracranial pressure presents. Generally, this results from CSF leakage, which may occur as a result of trauma, surgery, or conditions such as dehydration. Decreased ICP may also occur because of **brain atrophy**, which is a loss of neurons and synapses sometimes caused by disorders such as MND, infections, and cerebral palsy. Keep in mind the principle of the Monro-Kellie doctrine that any change in the volumes of a patient's brain, blood, or CSF causes intracranial pressure changes.

Clinical Manifestations

The clinical manifestations of decreased ICP typically include headaches, which may vary from mild to severe and may be dull or throbbing. Often, patients can relieve their headaches by lying flat. Other clinical manifestations of decreased ICP may include poor reflexes, dizziness, lightheadedness, lack of orientation, and blurred vision as changes occur in cerebral blood flow. Patients may also experience ringing in the ears, along with a sense of imbalance, and their neck may feel stiff and/or painful. Some patients with ICP also have gastrointestinal symptoms, such as nausea and vomiting.

Assessment and Diagnostics

As with IICP, to assess decreased ICP, nurses and other members of the patient's health-care team should review the patient's medical history and conduct a physical examination. The assessment should consider the patient's overall behavior, visual acuity, reflexes, orientation, and coordination and functioning.

Diagnostics and Laboratory Values

Diagnostic tests to identify decreased ICP may include MRIs, CSF pressure measurements, and a neurological examination. MRIs may show problems such as sinus engorgement, pituitary enlargement, and subdural hematomas that are causing decreased ICP. CSF pressure measurement may yield a low pressure reading. Imaging may show a problem such as **brain sagging**, which is a disorder that causes cognitive dysfunction and other issues typically associated with MND. Brain sagging causes decreased ICP and is diagnosed when imaging shows the brain in a sagging position (Liaquat & Jain, 2023).

Nursing Care of the Patient with Decreased ICP

Low intracranial pressure is generally not considered an acute clinical concern like IICP, which is life-threatening and requires emergency treatment. However, because normal range ICP is necessary to ensure proper cerebral perfusion and neurological function, patients should receive treatment to restore their ICP to an appropriate level.

Recognizing Cues and Analyzing Cues

To recognize the cues of decreased ICP, nurses should conduct a physical examination of the patient and note issues in their level of consciousness, pupillary response, motor function, speech, and vital signs. Issues that provide cues of decreased ICP include positive or negative changes in a patient's blood pressure, mental alertness, ability to speak, reflexes, visual acuity, and other vital signs and behaviors, including nausea and gastrointestinal issues. If applicable, nurses may also find cues in the readings of the patient's ICP monitoring device, such as a parenchymal monitor. To analyze these cues, nurses should consider whether they deviate from normal for the patient.

Prioritizing Hypotheses, Generating Solutions, and Taking Action

The analysis of the data gained through the nursing assessment can enable the nurse to prioritize hypotheses. The findings may include cues, such as a lack of mental alertness, blurred vision, and low blood pressure, as well as test results such as sagging brain or low CSF pressures. When such cues are part of the findings, the nurse may conclude that the patient has decreased ICP. The nurse should generate solutions to decrease or maintain ICP and take actions to help the patient, which may include those portrayed in Table 17.2.

Nursing Care	Rationale
Complete focused neurological assessments.	Changes in LOC, pupillary response and shape, motor function, speech, and vital signs indicate health issues.
Monitor vital signs.	VS are controlled in the medulla oblongata/brain stem, and worsening changes can signal dehydration of brain tissue.
Place patient in flat HOB position.	Flat HOB positioning can increase ICP because ICP tends to be higher when patients are in a flat position.
Monitor and maintain fluid and electrolyte balance.	Disruptions in hydration could affect ICP.
Monitor ICP levels.	Compare ICP levels to baseline.
Support oxygenation and ventilation.	Maintain patient's airway and assist with respiratory care to ensure adequate oxygenation and ventilation. Patients with head trauma may be in an induced coma and on ventilator support.
Monitor intracranial pressure.	Follow hospital protocols to obtain ICP readings and alert the provider of any worsening trends.

TABLE 17.2 **Nursing Interventions for Patients with Decreased ICP**

Evaluation of Nursing Care for the Patient with Decreased ICP

The desired outcome for patients with a decreased ICP is a higher level of ICP. To determine if the patient's ICP is higher, nurses should use pressure measurements as well as evaluate the results of the patient's lab tests, such as MRIs and neurology examination.

Medical Therapies and Related Care

As with IICP, once patients are diagnosed with decreased ICP, treatment and medical therapies should focus on the cause of the condition. Because the most common cause of decreased ICP is a CSF leak in the brain or lumbar spine, treatment options may include an **epidural blood patch**, which is the process of injecting a small amount of autologous blood into a patient's epidural space to plug the leak. If the patient's decreased ICP is caused by other issues, such as dehydration, treatment should focus on therapies, such as rehydration, to restore equilibrium to the brain's water balance. Therapies such as potassium supplements and salt tablets, as prescribed by the patient's provider, may be helpful.

17.2 Acute Disorders of the Nervous System

LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the pathophysiology, risk factors, and clinical manifestations for brain tumors, Guillain-Barré syndrome, and meningitis
- Describe the diagnostics and laboratory values in the disease of brain tumors, Guillain-Barré syndrome, and meningitis
- Apply nursing concepts and plan associated nursing care for the patient with brain tumors, Guillain-Barré syndrome, and meningitis
- Evaluate the efficacy of nursing care for the patient with brain tumors, Guillain-Barré syndrome, and meningitis
- Describe the medical therapies that apply to the care of brain tumors, Guillain-Barré syndrome, and meningitis

Acute disorders of the nervous system include injuries and conditions caused by trauma as well as sudden-onset diseases that can compromise neurological functioning. This section will explore brain tumors, Guillain-Barré syndrome, and meningitis.

Approximately one million Americans have a primary brain tumor, and in 2023, brain cancer was the tenth leading cause of death among patients with cancer (National Brain Tumor Society [NBTS], 2024). The median age for diagnosis of a brain tumor is 61 years. Although most brain tumors occur among adults, almost 4 percent of cases occur in children aged 14 or younger. The majority of brain tumors are benign, and patients learn to live with them. But about 28 percent of brain tumors are malignant. During 2023, almost 19,000 people died from a brain tumor (NBTS, 2024).

Guillain-Barré syndrome (GBS) is a less common neuropathy causing central nervous system weakness that can lead to paralysis. GBS occurs when the immune system fails, possibly as a result of infection, and attacks the body's peripheral nerves. The estimated annual incidence rate for GBS is one to two cases per 100,000 individuals (Nguyen & Taylor, 2023).

Meningitis is an infection that causes inflammation in the brain and spinal cord. Meningitis has five types—bacterial, viral, fungal, parasitic, and amoebic. Bacterial meningitis is the most serious and may even cause death. Viral is the most common type and also the least serious, with some patients recovering without medical treatment. Regardless of the type of meningitis, patients should be monitored and seek medical treatment as needed.

To successfully manage acute neurological disorders—including tumors, GBS, and meningitis—nurses must understand the fundamental principles of nervous system anatomy and physiology (Figure 17.4). The nervous system is divided into the central nervous system, which includes the brain and spinal cord; and the peripheral nervous system, composed of all of the spinal nerves that innervate the body's muscles.

The peripheral nervous system is further divided into the following systems:

- autonomic system, which regulates internal organs and glands

- somatic, or muscular response, system, which helps control voluntary movements and processes, such as the senses of sound, touch, smell, and taste

The autonomic system is further divided into two systems:

- sympathetic system, which controls the fight, flight, or freeze arousal response
- parasympathetic system, which controls the feed and breed, or rest and digest, calming response

The somatic system is further divided into two divisions that serve as a balancing force within the body to maintain homeostasis:

- sensory input division
- motor output division

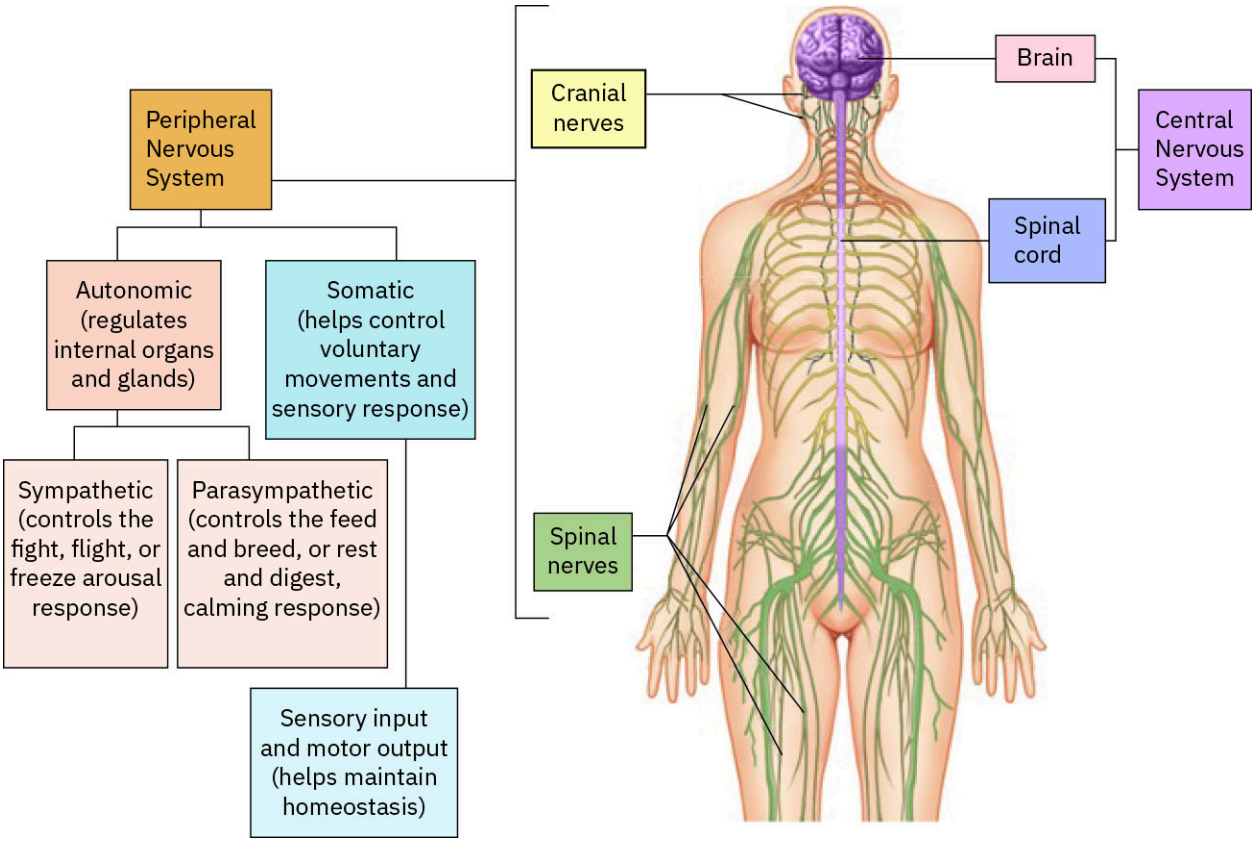

FIGURE 17.4 The divisions of the nervous system include the autonomic, somatic, and sympathetic systems. (credit: modification of work from Cenveo on AnatomyTool.org, attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license, original creator should also be credited)

Brain Tumors

A **brain tumor** is any abnormal growth of cells found within the brain or near it. Typically, a brain tumor, which can be **benign** (noncancerous) or **malignant** (cancerous), results from unchecked cell division and abnormal tissue growth. Benign brain tumors generally grow slowly and rarely spread to remote parts of the body. Although benign tumors are not cancerous, they can be dangerous if they constrict or damage areas of the brain. Malignant brain tumors usually grow fast and spread, moving aggressively through the brain's tissue layers and possibly into the spinal column.

Given the brain's complex functions and delicate anatomy, diagnosis of brain tumors can be challenging. Brain tumors are classified based on their location, behavior, and cell type. Whereas **primary brain tumor**s originate within or near the brain itself, **metastatic brain tumor**s, also referred to as secondary tumors, originate elsewhere in the body—such as the lung, breast, or colon—and then spread into brain tissue.

LINK TO LEARNING

The American Brain Tumor Association (https://openstax.org/r/77BrTumorAssoc) provides information for patients and health-care professionals about brain tumors, research, and resources.

Pathophysiology

Brain tumors involve genetic, molecular, and cellular changes, which contribute to abnormal cell proliferation in the central nervous system or brain. When cells do not experience **apoptosis**, which is the normal, controlled process of cell death, cancer may occur. Cancer cells have uncontrolled division and produce additional abnormal cells when they duplicate. These cells are undifferentiated and may compress blood vessels and vasculature. They also outgrow their own vasculature and sometimes develop new vasculature, while releasing toxins to surrounding tissues.

Cancers, including brain tumors, are varied and have different causes. Medical professionals are not certain what causes brain tumors, but typically, brain tumors result in genetic and molecular alterations, abnormal cell proliferation, **angiogenesis** (the formation of new blood vessels), infiltration and compression of normal body tissues, obstruction of CSF flow, and abnormal immune response.

Genetic and molecular alterations in oncogenes and tumor suppressor genes play an integral part in brain tumor onset. Typically, **proto-oncogene**s enable cells to stay alive by growing and dividing properly. Their work is complemented by that of tumor suppressor genes, which control cell divisions, while also repairing DNA errors and forcing cells to die when they reach the end of their lifespan. If patients experience DNA alterations that affect the functioning of proto-oncogenes and tumor suppressor genes, brain tumors may result. When a proto-oncogene becomes mutated, it is known as an **oncogene**.

One goal of cancer research is to determine the triggers that turn on oncogenic genes and turn off tumor suppressor genes. Research has identified contributing factors, including obesity, poor diet, stress, and smoking.

Types of Brain Tumors

Brain tumors include several types of benign and malignant growths. The benign tumors include the following (American Association of Neurological Surgeons [AANS], n.d.):

- **meningioma—**the most common type of benign intracranial tumor. As their name suggests, meningiomas begin growing in the meninges around the brain and spinal cord.
- **schwannoma—**common type of benign brain tumor found in adults. Schwannomas are found near nerves and may displace a nerve rather than invading it. Although schwannomas are benign, they can be serious health threats, even causing death, if they exert too much pressure on nerves and/or the brain.
- **pituitary adenoma—**also common, this type of benign tumor begins in the pituitary gland. Typically, pituitary adenomas affect individuals in their 30s and 40s, although children may have them.
- **craniopharyngioma—**typically arises from the pituitary gland and becomes embedded deep in the brain near critical structures. Patients with craniopharyngiomas usually need hormone replacement therapy, even though these tumors are benign.
- **chordoma—**rare, slow-growing tumor that generally occurs in individuals between the ages of 50 and 60. Typically, chordomas are found at the base of the skull or in the lower spine.
- **gangliocytoma—**rare tumor that involves the neoplastic nerve cells, which are nervous system cells that have become cancerous, and typically occurs in young adults.
- **glomus tumor—**rare tumor that occurs in the head and neck, often near the jugular vein.

The more serious brain tumors are malignant. The most common type of malignant brain tumor is a **glioma**, produced from the brain's glial cells. A **glial cell** is a supporting cell that provides nourishment to neurons. The different types of malignant brain tumors include the following (AANS, n.d.):

- **astrocytoma—**common type of glioma that grows from astrocytes. An **astrocyte** is a star-shaped glial cell that forms part of the brain's supportive tissue. Typically, astrocytomas form in the brain's cerebrum and can occur in individuals of all ages.

- **glioblastoma multiforme (GBM)—**the most invasive of the glial tumors. GBMs tend to be comprised of multiple types of cells, including astrocytes and oligodendrocytes, and they tend to grow quickly, spreading to other tissues. GBMs typically affect individuals between ages 50 to 70 and tend to occur in men more than women. For individuals who have a GBM, the prognosis is usually poor.
- **medulloblastoma—**typically occurs in children, affecting the cerebellum, and tends to be high-grade. Medulloblastomas usually respond to chemotherapy and radiation, making them more treatable than some brain tumors.
- **ependymoma—**less common brain tumor that occurs when the ependymal cells that line the ventricular system experience a **neoplastic transformation**, which occurs when oncogenes are activated while tumor suppressor genes are inactivated.
- **oligodendroglioma—**occurs in the cells that produce the brain's myelin, which insulates the brain's wiring.

Clinical Manifestations

Brain tumor symptoms vary according to the tumor's location, size, and growth rate. Generally, all brain tumors cause headaches. Other common symptoms include vertigo, nausea, fatigue, and changes in appetite. Additional manifestations, depending on the part of the brain affected by the tumor, include the following (Mayo Clinic, 2023a):

- Frontal lobe tumors tend to cause personality changes, disinterest in normal activities, forgetfulness, balance issues, and difficulty walking.
- Parietal lobe tumors, in the upper middle section of the brain, typically cause issues with the senses, including hearing and vision problems.
- Occipital lobe tumors, in the back of the brain, may cause vision problems, including blindness.
- Temporal lobe tumors, on the lower sides of the brain, may cause memory loss as well as issues with the senses, such as tasting or smelling something that does not exist.

Assessment and Diagnostics
